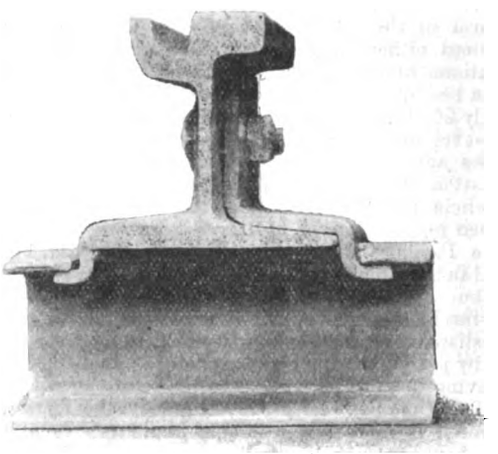
Some interesting information about lightning arresters for alternating and continuous current circuits is contained in pamphlet No. 182, just issued by the British Thomson-Houston Company, Limited, Rugby, to supersede Nos. 113 and 70. Tramway and railway motors are especially exposed to danger from lightning discharges, as the frames are always connected to earth. Discharges may take place from the line to earth conductors simultaneously at several points, and under these



The "Ratqua No. 2" Rail Anchor.

conditions the generator current, though not of sufficient E.M.F. to start an arc across the air-gap of the arrester, is capable of maintaining one or several arcs started by the lightning discharge. These arcs, if continued, would not only destroy the arrester, but would in many cases permit such an excessive flow of current as to overload or destroy the generator or other apparatus. Provision has been made in B.T.H. lightning arresters for extinguishing the arcs which would be formed in this manner. The company's alternating-current lightning arresters consist of a group of metal cylinders (Fig. 1) arranged with short air-gaps between them, and with a non-inductive resistance in series with the air-gaps. The action of the arresters is dependent upon the cooling effect of the metal cylinders, aided by the periodic

Digitized by Google

passage of the generator current through zero value, and on the non-inductive series resistance being of sufficient value to limit the flow of the dynamo current, but not sufficient to impede the progress of the lightning discharge. These arresters have been standardised for all voltages up to 25,000 volts, and they have been designed for and successfully used on line voltages up to 60,000 volts. Owing to the fact that under numerous conditions destructively high potentials may exist between conductors on alternating-current circuits, it is often necessary to arrange a discharge path between the conductors, as well as from conductors to earth. A special arrangement of arresters has been

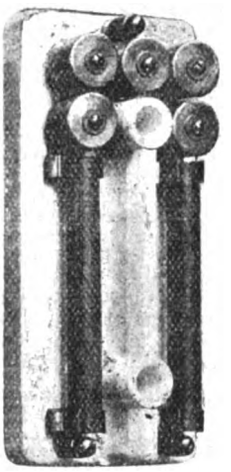


FIG. 1.—B.T.H. Type "GE" Alternating-Current Lightning Arrester, 2,000 Volts, Double Pole.

designed for this purpose, known as the "multiplex" arrester, the connections of which are shown for the particular case of a three-phase circuit in Fig. 2 herewith. The feature of the multiplex arrester, as contrasted with star or delta connected arresters for use on systems where the mid point is not earthed, is that suitable protection is afforded at the same time both for discharges between phases and for discharges to earth. Star-connected arresters do not provide adequate protection between phases, whilst delta-connected arresters do not provide for discharges to earth. The construction of an arrester for

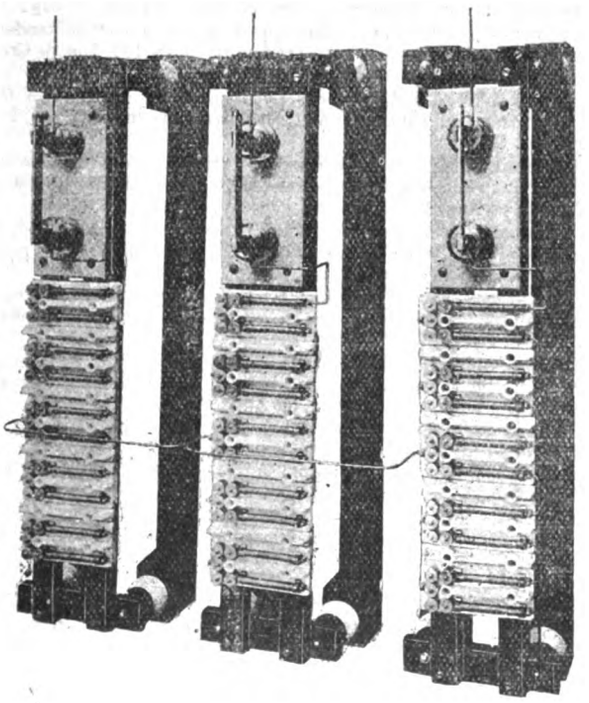

FIG. 2.—B.T.H. Type "GE" Alternating-Current Lightning Arrester, with Multiplex Connections for 12,500 Volts.

continuous-current circuits involves the same general principles as an arrester for alternating-current circuits, but in view of the fact that it is much more difficult to rupture a continuous-current arc than an alternating-current arc, some additional means are necessary for breaking the arc after a discharge has taken place. The magnetic blow-out type of lightning arrester, as supplied by the British Thomson-Houston Company, has been found to be most reliable for this service. The arrester consists of a single spark gap with a non-inductive resistance in series therewith to limit the discharge current. The spark gap is protected by the well-known magnetic blow-out, the coil of which is a shunt to a portion of the non-inductive resistance. The lightning discharge passes directly through the spark gap and resistance to the ground, and should any current from the generator follow the lightning discharge and tend to maintain the arc, such current will pass through the blow-out coil and produce a strong magnetic-field, thereby blowing out the arc. The magnetic blow-out arrester is furnished for lighting and power circuits from 60 to 375 volts, for railway and power circuits from 250 to 850 volts, and for series arc circuits from 2,000 to 6,000 volts. The box and cover of the arrester are made of glazed porcelain, and the spark-gap terminals are threaded, and attached to the lid of the box, thus affording a ready method of adjustment, positive grip on the terminals, and easy access for inspection and cleaning.

COMPANIES' MEETINGS AND REPORTS

GREAT NORTHERN AND CITY RAILWAY.

The fourteenth half-yearly meeting of this Company was held on the 4th inst. at the Westminster Palace Hotel, S.W.

The EARL OF LAUDERDALE, in moving the adoption of the report and accounts, stated that the receipts from all sources had increased by £9 730 during the six months ending June 30 last, as compared with the half-year ending Dec. 31 last. The average earnings per week were £1,778, as against £1,404 during the same period, showing an average increase of £374 per week. The passenger traffic was at at the rate of 245,830 per week, as against 201,062, or an increase of 44,768. These figures were exclusive of season tickets, and were most encouraging Since the opening of the line they had had a continuous increase, and he hoped that would be maintained in the future. He was glad that building operations in the districts between Wood Green and Tottenham were being extensively carried out. This all contributed additional traffic to their line, seeing that they had formed very convenient connections at Finsbury Park with the tramway services of that district. The arrangement for three-rate season tickets was in full operation, and payments were regularly made by the Great Northern Railway Co. to this Company. He wished to say, as the question was asked at the last general meeting in regard to the working expenses that the rate payable to Messrs. Pearson on this account, and until the Company took over the line, was 50 per cent. of the gross receipts. He did not see at present why, when they took over the line, this should be exceeded. Of course, they must clearly understand that whether this would really be so or not, must depend materially upon the increase or otherwise of the traffic; meanwhile, Messrs. Pearson had informed them that the ratio of working expenses to gross receipts had diminished. Since the opening of the line they were in the position which enabled them to deal with a large increase in traffic without materially affecting the working expenses. The number of passengers carried per car mile had increased from 5·65 to 7·68 as compared with last year. Provision was being made for additional rolling stock to meet the demands of the expected increase in the winter traffic. Contracts had been given for the supply of additional cars, and these would be delivered from time to time, commencing in October next. The directors were still of opinion that the extension to Lothbury should be proceeded with as soon as the raising of the necessary capital admitted of this being done.

The report was unanimously adopted.

TYNESIDE TRAMWAYS.

The half-yearly meeting of this Company was held last week at Newcastle, Lord Armstrong presiding.

The report stated that the surplus of receipts over expenses was £3 151. 10s. 3d., which, with the balance from last half-year of £58. 6s. 10d., made a total to the credit of profit and loss account of £3,209. 17s. 1d., and after deducting interest for debentures, loans, etc., there remained an available balance of £1,604. 9s. 2d. Out of this the directors proposed the payment of a dividend at the rate of 2 per cent. per annum, leaving £265. 14s. to be carried forward. Notwithstanding the electrification of the North-Eastern Railway, the surplus of traffic receipts over working expenses shows a material increase compared with any previous half-year. The sanction of Parliament has been obtained to the issue of the remaining capital of the Company, either as preference or ordinary shares. The question of depreciation will, as heretofore, be dealt with at the close of the financial year.

The report was adopted.

CHLORIDE ELECTRICAL STORAGE.

The report for the year ending June 30 shows a trading profit of £27,298. 3s. 3d. After deducting debenture interest, depreciation, and interim dividend on preference shares, the available balance for the year is £4,965. 6s. 11d., to which must be added £7,013. 13s. 4d. brought forward from last year, making a disposable balance of £11,979. 0s. 3d. The directors propose the payment of a dividend of 6 per cent. on the preference shares for the financial year, less interim dividend already paid, and a dividend of 8 per cent. on the ordinary shares, free of income tax, together amounting to £4,520, and to carry forward the balance £7,459. 0s. 3d. The retiring directors are Mr. W. Bannister and Mr. J. de Berniere Smith, who, being eligible, offer themselves for re-election. The auditors, Messrs. Parkinson, Mather, and Co., chartered accountants, also offer themselves for re-election.

Digitized by Google

LIVERPOOL OVERHEAD RAILWAY.

The half-yearly meeting of this Company was held at Liverpool on Tuesday, Sir William Forwood presiding.

The CHAIRMAN stated that for the first time in the history of the Company they had been unable to pay a dividend on the ordinary shares. The railway had been most successful in promoting and assisting trade and cheapening the expenses of the port. It would have been of still greater service to the port if the Dock Board had permitted it being constructed for goods as well as passenger traffic. Extensions of the line had been carried out from time to time, all proving valuable feeders, and there was no doubt that but for the introduction of the electrical tramways system by the Corporation the prosperity of the railway would have continued, and to-day it would have been one of the most flourishing concerns in the country. Little did the directors think that the most up-to-date method of traction would so soon have to give place to the electric tramway. That, unhappily, was their misfortune; but they had not stood idly looking on and taking this competition "lying down." They had done their utmost to remodel their methods, by accelerating the service and lowering the fares, in which direction they had gone as far as was prudent. Last half-year they carried nearly 4½ million passengers, the reduction from the best half-year being only 233,000 passengers, but the reduced fares gave them a considerably smaller return. They also suffered keen competition from the electric service on the Lancashire and Yorkshire Railway at the north end of the overhead system. In the endeavour to recoup their losses they were arranging for a through service of trains on the Southport line, which they hoped would restore a good part of the traffic they had lost.

The report was adopted.

CAPE TOWN CONSOLIDATED TRAMWAYS AND LAND.

The fourth ordinary general meeting was held at the offices, 1, London-wall-buildings, Baron Emile B. d'Erlanger presiding.

The CHAIRMAN reviewed the position generally, and quoted figures to show the severe period of industrial oppression through which the district was passing.

The report was adopted.

A resolution was afterwards passed approving the arrangements made by the Board for obtaining from Messrs. Erlanger and Co. and Messrs. Wernher, Beit, and Co., in equal shares, a loan, as and when required, to the amount of £26,000, carrying interest at 6 per cent. per annum, and authorising the directors to borrow from the same two firms any further sum which might be necessary for the Company's purposes.

NEW COMPANIES REGISTERED.

Patent Electric Carbonising Co., Limited.—Capital, £2,000. Objects: To acquire patent No. 4 593 of 1905, granted to S. Roberts, of the Observatory, Liversedge, Yorks., or any other patents relating to electric or other processes of carbonising wool waste, nails, rags, and fibrous substances, and to turn to account the same.

North Melbourne Electric Tramways and Lighting Co., Limited.—Capital, £200,000. Objects: To acquire the benefit of an Order in Council of the State of Victoria and its dependencies, entitled the "Town of Essendon and the Borough of Flemington and Kensington Electric Lighting and Power Order, No. 21, 1904," and of a further Order in Council, made on May 4, 1904, under the authority of the Tramways Act, 1890, relating to the construction of electric tramways in the town of Essendon and the borough of Flemington and Kensington, and to carry on the business of engineers, electricians, etc. Registered office: Worcester House, Walbrook, E.C.

Illuminated Signs, Limited.—Capital, £3,000. Objects: to carry on the business indicated by the title and that of electricians, suppliers of light and power. Registered office: 21A, Manor-street, Clapham, S.W.

E. Brook, Limited.—Capital, £5,000. Objects: to acquire the business of electrical engineers carried on at Threadneedle-street, Huddersfield, by E. Brook, and to carry on the same and the business of manufacturing electricians, mechanical engineers, etc. Registered office: Threadneedle-street, Huddersfield.

Liens Registered.

Northern Counties Electricity Supply Co., Limited.—A trust deed dated July 14, 1905, to secure £100,000 debenture stock, created by resolution of July 3, 1905, has been registered. Property charged: The company's freehold and leasehold lands and hereditaments at Cowpen Quay, Alnwick and Hirst, all in Northumberland, at Merrington, Felling, Shildon, Hartlepool, Heworth and Hebburn, all in Durham, and at Thirsk and Malton, both in Yorkshire, and its other assets, present and future, except uncalled and unpaid capital. Trustees—C. Emmott, Snow Hall, near Darlington; Major G. F. T. Leather, Hiddleston Hall, Belford, Northumberland; and F. Millburn, 6, Fenham-terrace, Newcastle-on-Tyne.

Electric Light Insurance and Maintenance Co. (1904) Limited. A charge on 150,000 electric lamps, dated July 27, 1905, to secure £500, has been registered. Holders: Wm. Whiteley, Limited, Westbourne-grove, W.

Ferranti Limited, Hollinwood, near Manchester.—Trust deed, registered Aug. 9, for securing £100,000 first mortgage debenture stock; trustees: H. R. Boyce, Winchester House, E.C., William Jones, of Manchester; charged on leasehold property at Failsworth and Manchester, the undertaking, and all other property and assets, present and future, including the uncalled capital; and debenture registered Aug. 9, for £50,000; holders: Parr's Bank Limited; charged similarly to the above debenture stock, but subject thereto.

LEGAL INTELLIGENCE.

DUST DESTRUCTOR.

In the Chancery Division last week Mr. Justice Farwell heard the action brought by the Attorney-General to restrain the Pontypridd Urban District Council from using any part of a plot of land situate at Gwern-y-gerwn, Treforest, near Pontypridd (which was acquired by the Urban District Council in 1902 from the trustees of the late Lady Llandover's will for the purpose of erecting a station for generating and supplying electric energy) for any other purpose than that for which it was acquired, and in particular to restrain them from erecting a dust destructor on a portion of the land which the trustees allege will cause a nuisance and deteriorate the value of the Llandover estate property in the neighbourhood.

Mr. DANKWERTS, K.C., for the defendants, contended that the destructor was admissible as part of the electric station plant because it was by the heat produced by the destructor that the necessary steam boilers of the station would be worked in the production of electricity. The learned counsel cited several authorities in support of his contention.

HIS LORDSHIP, in giving judgment, said that the proposition by the defence that they had power to use the land as they proposed was very wide-reaching and entirely contrary to the powers given to the Council as to the supply of electricity. He could not apply that principle to the present case. He could find nothing in the Electric Lighting Act which would allow him to treat them other than separately, and he, therefore, held that the action of the defendants was *ultra vires*, but he granted an injunction accordingly, with costs, but he made an order for no costs on the question of nuisance.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Sophia.—The District Finance Commission require tenders for telegraph material by Aug. 25.

Florianopolis (Brazil).—The Municipality require tenders for the lighting of the town by Oct. 2.

Turn-Severin (Roumania).—The Mayor invites tenders for the electric lighting of the town. Tenders by Sept. 10.

Pentypridd.—The Urban District Council invite tenders for (Section A) permanent way. Tenders by 12 noon on Sept. 2.

Olympia 1905 Exhibition.—The Executive Committee invite tenders for the loan or hire of 300-kw. direct-coupled steam set.

Edinburgh.—Tenders are invited for the electric lighting installation at the mortuary buildings, High School Yards, Edinburgh, for the Lord Provost, Magistrates, and Council. Tenders by Sept. 11.

Paris.—The Post and Telegraph Department require tenders for rubber-insulated copper wire. Tenders to above, 103, Rue de Grenelle, by Aug. 24.

Madrid.—The Public Works Department require tenders for the construction and working of an electric tramway in Zaragoza. Tenders by Sept. 12.

Madrid.—The Public Works Department require tenders for the construction and working of an electric tramway in Malago (Malaga). Tenders by Aug. 19.

Swansea.—The Corporation invite tenders for switchboard, transformer pillars, transformers, switchgear, etc. Tenders by noon on Aug. 26. See advertisement.

Taunton.—The Corporation invite tenders for a water-tube (straight) marine-type boiler, superheater, economiser, pipe extensions, etc. Tenders by Sept. 2. See advertisement.

Acton.—The Urban District Council invite tenders from manufacturers for the supply of arc lamp carbons and house fuse-boxes for a period of 12 months. Tenders by Aug. 21.

Larne (Ireland).—Tenders are invited for lighting the public streets and roads of the urban district of Larne by means of coal gas or electricity for three years from Aug. 1, 1906. Tenders by 10 a.m. on Sept. 2.

Alicante (Spain).—The Harbour Board (Junta des Obras del Puerto) require tenders for two electric cranes, capable of lifting 10.000 ko. and 1,500 ko. respectively. Tenders by Sept. 15. Estimate, 107,010·10 pesetas.

Chelmsford.—The Town Council invite tenders for lighting the public streets and public clock within the borough with electricity, gas, or other illuminating power for three or five years from March 25, 1906. Tenders by Sept. 8.

Earsdon (near Newcastle-on-Tyne).—The Urban District Council invite tenders for work in connection with the electric lighting of part of the district. Tenders by Aug. 18 to Mr. Alfred Dale, clerk, 85-86, Howard-street, North Shields.

Paris.—The Waterworks Department of the Municipality require tenders for supply and erection of motors, pumps, and generators for the proposed waterworks at Chantilly. For particulars apply to above authority. Tenders by Oct. 12.

Stalybridge.—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery, and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

Merthyr Tydfil.—Tenders are invited by the Urban District Council for the erection of refuse destructor plant capable of effectually burning 120 tons of refuse per day, together with all buildings and contingent works connected therewith. Tenders by Sept. 1.

Digitized by Google

Ashton-under-Lyne.—The Electricity Committee invite tenders for (Section A) one 500-kw. direct-current generator; (B) one water-tube boiler with superheater, to be worked in conjunction with a refuse destructor; (C) two superheaters for Lancashire boilers. Tenders by 12 noon on Sept. 2. See advertisement.

Erdington.—Tenders are required for the construction of Section No. 1 of the Erdington tramways, comprising the laying of the permanent way, including copper bonding, wood block paving, and other works incidental to the laying of about 2½ miles of double-track tramway, for the Tramway Committee. Tenders to the joint engineers, Mr. Robert Green (of Messrs. Pritchard, Green, and Co.), of 37, Waterloo-street, Birmingham, and Mr. Herbert H. Humphries, engineer to the Council, Public Hall, Erdington.

Municipal Board of Mussoorie (India).—The Municipal Board invite tenders for the supply, delivery, and erection at sites, in complete working order, of the following plant: (*a*) steel power pipes; (*b*) water-motors; (*c*) alternators with exciters; (*d*) switchboards with instruments and apparatus; (*e*) transformers; (*f*) induction motors; (*g*) pumps; (*h*) workshop machines. Also for the supply and delivery of the following: (*a*) bare copper wire for overhead mains; (*b*) insulators and lightning arresters; (*c*) arc and incandescent lamps; (*d*) telephone equipment; (*e*) workshop tools; (*f*) general stores. Specifications, form of tender, and general conditions can be obtained on application to Mr. C. H. Shanan, municipal electrical engineer, Municipal Office, Mussoorie, India (telegraphic address, Shanan, Mussoorie), on payment of a deposit of Rs.75 (£5), which amount will be returned on receipt of a bona fide tender. Tenders by Oct. 23. See advertisement in previous issue.

RESULTS OF TENDERS.

Manchester.—The Corporation have accepted the tender of Veritys Limited for their "Aston" motors for the 2, 3, and 4½ h.p. sizes.

Darlington.—The Corporation have accepted the tender of W. E. Dove and Co. for "Aston" motors, to be supplied by Veritys Limited.

Baroda.—The tender of Rowland Carr and Co. for the supply of arc lamp columns and carriers has been accepted by the Huzur Public Works Department for Baroda State.

Middlesex.—The County Asylum Authorities have placed with the Hart Accumulator Co., Stratford, London, the order for renewing battery at Wandsworth Asylum with 112 of their standard lighting-type cells.

Burton-upon-Trent.—The following tenders have been accepted for alterations and additions to the electric lighting, and also for alterations to be made to the heating apparatus at the town hall: Gough and Felgate, Uxbridge-street, Burton-upon-Trent, heating, £138. 14s. 9d.; J. Richards, High-street, Burton-upon-Trent, electric lighting, £199.

Islington.—The Borough Council have accepted the following tenders: Willans and Robinson, one 1,500-kw. steam turbo-generator, exciter, condensing plant, etc. (the alternator to be of Dick-Kerr's manufacture), £8,258; Balcke and Co., one natural-draught cooling tower in two sections, £1,118; John Spencer, Limited, 800ft. of 20in.-diameter steel rivetted pipe for circulating mains, together with 12 bends of the same diameter, £466. 12s.

Grimsby.—The following tenders have been received for electric lighting of the new highways yard:

Central Electric Co.	£96	4	0
D. J. Dolby	94	9	10
Robinson and Emerson	89	15	0
Northern Electrical Co.	85	0	0
A. C. Dickens and Co., Grimsby (accepted)	68	14	0

Accumulators.—The A.B.P. Accumulator Co. report the following orders: 27 cells, 82 type, 7 plates, 210 ampere-hour battery, for Riston, Lancashire; 55 cells, 83 type, 9 plates, 280 ampere-hour battery, for South Wales; 58 cells, 89 type, 21 plates, 700 ampere-hour battery, for Pudsey, Yorkshire; 230 cells, 86 type, 15 plates, 490 ampere-hour battery, for India; 254 cells, 86 type, 15 plates, 490 ampere-hour battery, for India; and also a maintenance contract from the Barnstaple Town Council for five years, at £120 per year.

Grimsby.—The Highways and Public Works Committee have received the following tenders for the fixing of an electric pump in the Doughty subway:

W. H. Allen and Son	£121	0	0
Crompton and Co.	88	0	0
D. J. Dolby	81	10	0
A. C. Dickins and Co.	59	8	0
Gwynne and Co.	95	0	0
Indiarubber and G. P. Telegraph Works	98	0	0
Northern Electrical Co.	72	0	0
Pulsometer Engineering Co.	96	0	0
Mather and Platt	90	0	0

Port Louis (Mauritius).—Messrs. Johnson and Phillips, of Old Charlton, Kent, have obtained the complete contract for the power generating plant and high-tension overhead transmission line for transmitting the energy generated over a distance of four miles for Port Louis, Mauritius, which includes the following plant: 2,700 foot run of 34in. diameter steel water pipes and fittings; 75-kw. single-phase alternator, with exciter, direct coupled to Pelton wheel of 103 b.h.p.; main and distributing switchboards; high-tension transmission line material, consisting of steel poles, overhead line wire, porcelain insulators for carrying line wire, lightning arresters, etc.; two 40-kw. single-phase transformers for transforming down to low tension; low-tension network main for street lighting, consisting of bare overhead line wire, insulators for carrying same, insulated cable for connecting to street lights; 1,000 incandescent lamp brackets, complete with necessary fittings and lamps for fixing on posts.

BUSINESS NOTES.

TRACTION.

Perth.—It is reported that the cars are ready for delivery as originally designed.

Belfast.—The work of reconstructing the central portion of the tramway system was commenced on Wednesday.

Bombay.—The introduction of electric traction on local trains in Bombay is being discussed.—*Indian Engineering.*

Dundee.—A post-card *plébiscite* is to be taken on the question of Sunday running, all replies to be sent in by Sept. 2.

Hastings.—There was a big rush for the trams round about Bank Holiday. From Aug. 4 to 10 no fewer than 186,896 passengers were carried.

Bath.—The Rural District Council and the promoters of the Lansdown light railway have practically agreed upon terms for road widenings.

Huddersfield.—The Tramways Committee have resolved to ask the Council to pay the employés at the rate of time and a quarter for Sunday labour.

Weymouth.—Apparently the Town Council have not yet made up their minds as to applying for powers to construct an electric tramway, the matter having been referred to committee.

Cleckheaton.—The Board of Trade have intimated that they are unable to assent to the application of the British Electric Traction Co. for leave to abandon their Spen Valley scheme. The company has been granted a month to make further arrangements.

Birmingham.—The tramways extension scheme entered upon another phase on Monday, when the process of reconstructing the line in Hurst-street, south of Bromsgrove-street, was commenced.

Musselburgh.—The success of the electric car service has been quite beyond the expectations of the management, and now after only nine months' traffic an extension of carshed accommodation is required. Four new cars, just delivered, make a total of 14 at the depôt.

Dewsbury.—On the Dewsbury, Batley, and Birstall steam tramways, the first of the kind established in this country, the final journey with that form of traction was made last week. The roads are now in the hands of workmen, who are preparing them for electric traction.

Notification.—A communication appeared in the Press the other day from Mr. W. Gentry Bingham, 80A, King's-road, Brighton, to the effect that the transfer of the electric lighting and tramways concession to the Bombay Electric Supply and Tramways Co. is subject to his approval.

Pontypridd.—On Saturday night the electric car service was brought to a standstill, owing to one of the overhead wires becoming disarranged. Mr. Teasdel, the engineer, was fortunately passing at the time, and at once took steps to have the wire repaired, which was done in a comparatively short time.

Felixstowe.—The trial trip of the three new electric cars which are to run on the new pier at Felixstowe took place on Monday morning, Mr. Lambert, the electrical engineer for the Coast Development Corporation, being present. The trip was perfectly satisfactory, and the Board of Trade inspection is expected to take place in a day or two.

Sunderland.—The tramway company are pushing their extension rapidly forward, and it is expected that in a very short time electric trams will be running direct from Sunderland to Hetton, by way of Houghton-le-Spring. The company have only been at the work for six weeks, and in that time they have made a lot of progress. The rails are now laid practically into Hetton.

Light Railways.—The Board of Trade have confirmed the following orders made by the Light Railway Commissioners: Bath Electric Tramways (Light Railway Extensions) Order, 1905, authorising the construction of a light railway in the rural districts of Bath and of Keynsham, in the county of Somerset, being an extension of the existing and authorised undertaking of the Bath Electric Tramways, and the County of Middlesex Light Railways (Extension of Time) Order, 1905, amending the County of Middlesex Light Railways Order, 1901.

Blackpool and Fleetwood Tramroad.—The report for the half-year ended June 30 last states that, including the sum brought forward from last half-year, the balance of profit, after providing for debenture interest, is £3,852, and the directors recommend a dividend at the rate of 4 per cent. per annum, which will absorb £3,000, writing off a sum of £500 to depreciation reserve and £288 to general reserve, leaving a balance of £64 to be carried forward. The number of passengers carried during the half-year was 802,150. Receipts from all sources amounted to £10,389.

Stockport.—Colonel von Donop, representing the Board of Trade, last week inspected the new Lord-street line, a special car containing the inspector, members of the Tramways Committee, and officials, running over the new line, which is a comparatively short length. The inspector expressed himself as satisfied with the trial. Much satisfaction has been caused in Gorton and district now that the Urban District Council has been authorised to lay new tramways along Reddish-lane, Hyde-road, Wellington-street, and Gorton-lane. By the new route Stockport will be connected with Reddish, Gorton, Openshaw, etc.

Gosport.—At the meeting of the Urban District Council a letter was read from Mr. J. F. Glenn, engineer to the Provincial Tramways Co., with regard to the tramway scheme. Mr. Glenn explained that the Stoke-road line would be commenced in about three months' time, and with regard to the Fareham line, he pointed out that the company had considerable difficulty with the War Department in respect to a piece of land near the present terminus. The price demanded by the War Department was something like £1,250 an acre, and as that was

Digitized by Google

quite impossible he had decided to lay the lines at the side of the road as near to the War Department hedge as possible.

Leeds. — Some members of the Tramways Committee visited Calverley the other day and looked over the route of the proposed tramway between the village and the Leeds boundary at Rodley—the present terminus of the municipal system. The Calverley District Council have obtained a provisional order for constructing tramways in their area, but they are inviting the Leeds Corporation to take over these powers and extend its own system along the mile and a half of roadway between Rodway and Calverley village. Nothing definite has been settled, but the Tramways Committee, which is said to be favourably disposed towards the scheme, will shortly have the matter before it.

Salford.—From the annual report, just to hand, of the Corporation trams for the year ending March 31 we observe that the income amounted to £209,672, leaving a gross profit of £74,780. Out of this capital charges, etc., absorb £38,105, a sum of £16,168 is accounted for by rents paid to other authorities, £8 934 is placed to depreciation account, and £13 000 is handed over to the borough fund. The car miles were 4 884 590; the passengers, 39,213,560; units of energy consumed, 6,927,805; average traffic revenue per mile, 10·29d.; average working expenses (excluding power) per mile, 4·51d.; average working expenses (including power) per mile, 6·62d.; percentage of expenses to receipts, 64 per cent. It is gratifying to note that the figures as to traffic show a steady increase.

Sheffield.—At the meeting of the City Council the lord mayor proposed a resolution to appoint a committee to consider the subject of the tramway finances, and particularly the question of the adjustment of fares, and the further development of the tramway undertaking. His Lordship expressed the opinion that the adjustment of the fares was absolutely necessary if the finances of the undertaking were to be maintained on a sound basis. There was no tramway system in the kingdom which carried its passengers so far for 1d. as they did in Sheffield, with the result that the revenue was insufficient to meet the proper charges for renewals. Eventually the following resolution was carried: "That the question of tramway finance, and particularly the adjustment of fares, and its relation to the future development of the tramways undertaking, be referred to the Tramways Committee with instructions to report thereon."

Leith.—The Board of Trade inspection of the first section of the new electric tramway system in Leith was made on Saturday by Colonel Von Donop, among those present being Mr. James More, tramways engineer; Mr. W. P. Rutherford, electrical engineer; Mr. John Wilson, tramways manager; and Mr. W. Relph, assistant tramways engineer. After Colonel Donop had inspected the car at the depôt, the journey to Craighall-road was begun. At one or two places on the route, Colonel Donop had the car stopped in order to examine and make inquiries regarding details of the overhead equipment, and the placing of the poles. Everything appeared satisfactory, and after the car was taken back to the foot of Leith-walk, and thence again over the Leith-walk section to Pilrig, Colonel Donop, it is understood, expressed himself satisfied with the inspection. It is probable that cars will be running on a part of the system this week.

Parliamentary Bills.—At the eleventh hour the North-East London Railway Bill, to which we referred last week, was agreed to by the House of Commons and allowed to be proceeded with, the Lords' amendments being acquiesced in. The Newry, Keady, and Tynan Light Railway Bill was also passed. The Tramways Orders Confirmation (No. 1) Bill came before the Committee on Unopposed Measures last week, the Deputy-Chairman of Committees (Mr. Laurence Hardy) presiding. The Bill confirms orders made provisionally by the Board of Trade empowering the Corporations of Bradford, Leeds, Keighley, and Pudsey to construct tramways. Mr. Bonnor Maurice explained that there was a contest in the House of Lords because the railway companies did not consider that they were sufficiently protected. The clause objected to had been struck out of the Bill and new ones inserted. These had been agreed to by all the parties interested, as well as by the Board of Trade. The Bill passed through committee, and was sent for third reading in the Commons.

Inquest.—Dr. Gordon Hogg held an inquest last week at Teddington on the body of Arthur Henry Scott, carman, of Elm-road, Kingston. Deceased was in charge of a load of hay in Hampton Court-road, and was sitting on the shaft when the van was run into by a tramcar. He was thrown off and struck by the car, receiving such serious injuries on the body that on arrival at Teddington Cottage Hospital he was found to be dead. The evidence of John Macdonald, driver of the electric car, was to the effect that the night was dark, and he could not see the van until within half a car's length of it. He saw no light on the van. He sounded his gong, and stopped the car within a length and a half, but it struck the rear of the van, startled the horse, and the deceased fell to the ground. The tramcar was going at about eight to nine miles an hour. Other witnesses stated that they heard no gong sounded, but the conductor corroborated the driver's statement that it was sounded. The jury returned a verdict that deceased died from an accidental fall from a van, but they considered the driver of the tramcar was to some extent to blame for not observing the van.

Heywood.—At the monthly meeting of the Corporation the town clerk reported receipt of sanction from the Board of Trade to the borrowing of £37,200 for the electrification of the tramways, to be repayable partly in 30 years and partly in 20 years. Councillor Popple (chairman, Tramways Committee) proposed the adoption of the Committee's report. He was sorry he could not say absolutely that they had arranged for the working of the Heywood trams by their neighbours. They had all but arranged with Bury; he might say that they had practically settled with Bury, and they had not lost heart with Rochdale. They had had many meetings and pleasant discussions, and to some extent some stormy discussions, and the Heywood representatives felt they could adopt either Bury's suggestion, if Rochdale would fall in; or they could adopt Rochdale's suggestion if Bury would fall in with it, but they could not have two systems, one on the one side of the borough and one on the other. He thought, however, he could say confidently that before they had another monthly meeting the thing would be arranged for the working of their system either by one neighbouring authority or by the two. If they could not agree with Rochdale, Bury was quite prepared to take over the whole system, including the Hopwood section. The minutes were approved.

Bury.—In the annual report of the borough engineer (Mr. A. W. Bradley) for the year ended March 31 last some interesting figures are given concerning the cost of the tramway track entrusted to Mr. Bradley. It appears that the net estimated expenditure after the routes had been definitely decided upon was £92,902. 6s. 7d., and the actual cost was £88,290. 1s. 10d., or £4,604. 4s. 9d. less than the estimates. The figures would have been even more favourable than they are but for one or two heavy contingencies having to be met which were not provided for in the estimates. The main amounts under this head are £1,489. 9s. 6d. for car depôt tracks and £708. 2s. 6d. for extra paving required by the Lancashire County Council in Tottington. Other extras included in the actual expenditure were an outlay on the temporary track and maintenance at Blackford Bridge during the rebuilding, part of which outlay will be recovered from the County Council, and the cost of repaving Crostons-brow owing to the alterations to the feeder bridge. The cost of work on the different sections, as ascertained by measurement at the prices of the contractor who carried out the earlier work, would have been £31,082. 10s. 8d., and the actual cost was £29,516. 4s. 9d., a difference in favour of the Council doing the work itself of £1,566. 5s. 11d. Mr. Bradley expresses the opinion that the Corporation have got full value both in labour and materials employed, and that the quality of the work was not inferior to that of a contractor. It was also completed within the time fixed.

Liverpool.—At the fortnightly meeting of the Tramways Committee the traffic returns for the fortnight ended Aug. 5 were submitted, and showed that the receipts amounted to £22,874. 19s. 5d., an increase of £157. 15s. 2d. over the corresponding period of last year; the passengers carried numbered 4,913,607, an increase of 79,809; and the mileage run was 474,156 miles, a decrease of 3,809. The general manager, Mr. C. R. Bellamy, submitted the following traffic return for the five days ended Bank Holiday, Aug. 7, covering the period of the Agricultural Show at Wavertree, together with the figures for the corresponding period of last year. The following are the increases in the receipts—viz.: Thursday, Aug. 3, £25. 10s. 1½d.; Friday, Aug. 4, £215. 12s. 9d.; Saturday, Aug. 5 £297. 4s. 9d.; Sunday, Aug. 6 £51. 15s. 4½d.; Monday, Aug. 7, £260. 16s. 10½d.—total, £850. 19s. 10½d. The mileage run for the Bank Holiday amounted to 45,945 miles, against 44 588 last year, an increase of 1,357, or 3 per cent. The passengers carried on the same day numbered 529,132, being an increase of 35,984 over the same day last year, or 7·3 per cent., while the receipts amounted to £2,702. 19s., against £2,412 2s. 1½d last year, an increase of £260. 16s. 10½d., or 10·7 per cent. The total mileage for the five days amounted to 182 469 miles, an increase of 7,466 miles over the corresponding period of last year, or 4·3 per cent. The passengers carried numbered 1,962,784, an increase of 141 045, or 7·7 per cent.; while the total receipts amounted to £9,478. 19s. 8d., against £8,627. 19s. 9½ d. last year, an increase of £850. 19s. 10½d., or 9·9 per cent. The receipts during the Agricultural Show would doubtless have been better but for the bad weather. The receipts for the Bank Holiday constitute a record, with the exception of Coronation Day.

London County Council.—The extension of tramways in the North of London is rapidly approaching completion. Hitherto the trams from Highgate-hill downwards have only come as far as the Archway, while those going northwards in that direction have turned off at the corner of Junction-road. Now, however, rails are being laid down from the Arch to Junction-road, which will thus fill up the gap of about a quarter of a mile and effect an important connection between the two systems. A large and representative South London Protest Committee on the House of Lords' rejection of tramways over the bridges is being formed, and includes Mr. J. W. Benn, M.P., Mr. John Burns, M.P., Mr. R. K. Causton, M.P., Mr. Will Crooks, M.P., Mr. J. Cumming Macdona, M.P., Dr. Macnamara, M.P., Mr. J. P. Nannetti, M.P., and the Mayors of Lambeth, Southwark, Woolwich, Deptford, Camberwell, Battersea, and Lewisham, with Councillor W. Westcott, of the Reformers' Club, St. Agnes-place, Kennington Park, S.E., as hon. secretary (*pro tem.*). A meeting will be called as soon as possible to decide what action shall be taken. There has been a baseless rumour in circulation that the County Council had abandoned the proposed Lordship-lane tramways because of the impossibility of getting cars beneath the railway bridge at Lordship-lane. The roadway will have to be lowered, as has been done on the Streatham line at Brixton Station, and on the Tooting line at Clapham-road Station. The County Council is proceeding with widenings, etc., in connection with the trams over Denmark-hill. At the meeting of the North Metropolitan Tramways Co. on Wednesday the agreement with the County Council for the surrender of the balance of the company's lease was ratified. At a meeting on Wednesday of the South London Protest Committee, referred to above, the association was formally called into existence, and it was decided to use every effort in support of the Bill, which the committee hoped the County Council would reintroduce next session.

North-Eastern Railway.—At the half-yearly meeting of this company last week, Sir Edward Grey, who presided, stated that the dividend was ¼ per cent. less than for the corresponding period of last year. From the report it would be seen that there had been a falling off in the gross receipts of £28,184, but a reduction in the expenditure of £31,292, leaving an increase in the net receipts of

Digitized by Google

£31,080. It was not, therefore, the falling off in the gross revenue which was the cause. From the capital account it would be seen that they had to pay interest upon considerably more capital than was the case a year ago, and it required £36,000 more to pay a dividend at the same rate as a twelvemonth back. The real cause, therefore, of the reduction of the dividend was the increase in their capital. Had their capital remained the same as it was a year ago they would have been able to pay the same dividend. Turning to the electric train working at Newcastle, the Chairman said they had now a year's figures to work on, and comparison with the last year of steam working showed a gain in passengers of 20·9 per cent., and in receipts of 17·6 per cent. So far electrification of these suburban lines had resulted in some increase of net revenue and convenience to the public. In reply to a question as to whether motorcars were to be run in Hull streets in opposition to trams, Sir Edward said the company had no special plan in their minds when they obtained powers, and they had not yet developed any large scheme for making experiments. They should take the utmost care that none of their experiments were futile ones likely to be costly to shareholders. During the past half-year the company spent £36,000 in the Newcastle district on electric power and lighting, which had nothing to do with the electrification of the railway. This was part of a large expenditure they were incurring in substituting electric power for steam power in their Gateshead shops, the new warehouses in New Bridge-street, and all works of that kind in the Newcastle district. When it was completed they would be able to do away with the steam power they were now using, and by having electric power and lighting in their works they estimated that there would be a saving as compared with the older methods. The report, recommending a dividend at the rate of 4¾ per cent., was adopted.

Glasgow.—At the meeting of the Corporation last week, Mr. Hugh Alexander moved the adoption of the tramway accounts for the past financial year, particulars of which appeared in our issue of the 4th inst. He stated that he had not any wonderful tale to tell, but he could congratulate the members on the year's business. The revenue had risen by about £40 000, and out of that they had £10,000 of clear surplus. One little matter was not quite so satisfactory. The earning capacity per car-mile was steadily falling. Some years ago he had warned the house not to expect a growing increase in the surplus. During the past five years the earning capacity had fallen 1½d. That was due, not as some of their friends would be telling them, to their cars being run too far into the country, but because they had placed upon the streets something like 186 cars more than they had five years ago, and were travelling something like 88 miles more; and those two figures showed an increase far and away out of proportion to the natural increase in the population. The meaning of that was that the citizens within the tramway area were getting a much better service—a much more frequent and a much more desirable service—than formerly. The question of depreciation had been well looked after. The natural depreciation—or rather, he should say, the normal depreciation—had been met. They had set aside £81,000 for depreciation, which figured out at 3 per cent., not on an attenuated capital, but on their whole capital used since the tramways were inaugurated. They had not attempted to write down the depreciation on £1,783,000, which was their net liability to-day. In addition to that they had set aside £72,176, equalling 2½ per cent., for the renewal of the permanent way, which was considerably in excess of anything they set aside before. Notwithstanding that they had laid aside £450 per car mile to renew the track, it had been borne in upon the general manager and the committee that after using the track for five years they would require more than £450 per annum per car mile to renew the track when the time came to do so, and, therefore, on this occasion they laid aside £500 per car mile. After all that had been done, and £25 000 had been handed over to the common good, they had still a surplus of £93,000. Out of that they proposed to set aside £68,000, equal to 2¼ per cent., for special depreciation. When they took the normal depreciation, the fund for renewal, and the special depreciation, they had out of their working for the year just passed laid aside no less than 8 per cent. of the total capital employed. That was evidence that the tramway undertaking was being conducted on perfectly safe lines. After some discussion as to an extension of ½d. fares, the report was adopted. The inhabitants of Newton Mearns have appointed a second deputation to wait upon the Corporation in reference to an extension of the line.

Liverpool Accident.—The inquest upon the victims of the accident on the electrical section of the Lancashire and Yorkshire Railway was held last week, and we extract the following particulars of the evidence from the *Liverpool Post*: William Rimmer, the driver, said he had been in the employment of the company for 17 years. The Coroner: When you approached Hall-road, am I right in saying that you came to four signals—the outer distance, inner distance, outer home, and inner home?—Witness: Yes; the outer distance signal was "on"—that is, against the train. Am I right in saying that you are allowed to pass the outer distance signal even when it is against you?—Yes; you are allowed to pass them. You are also allowed to pass the inner distance signal. Witness added that the outer distance signal—No. 40—was against him. Was the inner distance signal against you?—Whilst I was travelling the 500 yards between the outer distance and inner distance signals the inner distance signal was taken off. That is the one for Hall-road. The Coroner: I do not want to press you, but do not you know as a matter of fact it is physically impossible to take off No. 39—the outer home signal—and give you a free road unless No. 38 is right for the main line?—Witness: When I got to the outer home signal the signalman was at the window of his box waving his green flag I put off the current and blew my horn to find out whether the signal was for me, and the signalman waved the flag continuously, showing it was for me, and I put on the current again. When I got to the end of the platform the inner home signal was then thrown on, I had not very much room, and at the time I noticed that the points were set for the middle siding. I at once shut off the current and applied the brake with all the speed I could. I had not sufficient room to pull up.—The Coroner next directed the attention of the witness to the rules and regulations for signalmen, and particularly to the regulation which stated that when a signal became defective or was not working efficiently, a competent person must be placed at the signal post with a hand signal. He asked the witness to point to anything in the rules which warranted him in accepting the signal.—The Witness said he took it for granted that the flag was for him. The pointsman was a competent man.—The Coroner: Can you show me in these rules anything that entitles you to accept a green flag waved violently from the cabin window as a signal for anything?—Witness: Oh, yes.—The Coroner: Well, I cannot find it.—Witness: If he had intended me to stop he would have given me the red flag.—Counsel for the company: You passed without receiving the verbal instructions required by this notice?—Witness: Yes, sir.—The foreman of the jury asked if the method of signalling used on this occasion had ever been used before.—Witness replied that when he was "firing" he remembered seeing it done several times.—Mr. Fletcher (the driver's solicitor): Was there any doubt in your mind as to your duty to obey the signalman?—Witness: It was my duty to obey the signalman.—The Coroner: You have raised a very serious point, Mr. Fletcher. Is it going to be seriously contended that when a motorman is in charge of an electric train and sees the signal against him, that he is going to pass a home signal with the waving of a green flag from the cabin window?—Mr. Fletcher: I think from this notice he is entitled to do so.—William Boote, the signalman, said that on the day of the accident he signed on at half-past twelve noon, and his duty would cease at at 8.30 p.m. When the Hall-road train which preceded the express was safely into the middle siding, signals 37, 38, 39, and 40 were against the express. It was not possible to get No. 40 signal down in favour of the express unless he first of all closed up the points. Both distance signals were against the driver. The Coroner: The driver told us that when he passed the outer distance signal, which was against him, he came to the inner distance, and that was for him. Could the inner distance signal be for him without the points being set for the main line?—Witness: That is mechanically impossible. He then he says he came to No. 38?—It was against him for a time, but No. 38 could have been in his favour, although the points were set for the main line. When he came to the home signals they were against him?—Yes. Were they bound to be against him mechanically?—Yes; I tried to work the home signal and the electric lock prevented me. Witness said that to get the express train on he waved a green flag. When he found the home signal would not work he tried several times to reverse the signal in favour of the driver. He also reversed the points several times to try and effect this. When he waved the green flag the express was almost at a standstill at the home signal 50 or 60 yards away. He did not say anything to the motorman, and he used no words when he waved the flag. The express then came on and went into the middle siding.—The coroner then called witness's attention to the regulation with regard to a properly qualified person waving a flag at the signal post when a home signal broke down, and asked him to point to any regulation authorising him to wave a green flag from the cabin.—Witness, in reply, said he did not want to delay the express, and he had no one to send down to inform the station-master.—The Coroner: Have you ever brought on a train in the same way as you did on this occasion?—Witness: No, sir, but the station-master has sent a train past the signals.—That was on verbal instructions after communication with you. Yes.—With the home signals against the approaching train the facing points are against the main line?—Yes. Does that not prove that being in a state of uncertainty you should have sent a hand signalman to look at these points and come and tell you, and then you must give instructions as to what the train must do?—Yes. You do not allege, do you, that there was anything in these rules which justifies you in doing what you did?—No. Witness stated that he was perfectly sober, but lost his head. He had three times complained in writing to the company of being overworked. He admitted that he would not have been reprimanded for stopping a train when the signal was against it if the matter were properly explained. An inspector stated that there was no rule that a man would be fined if he stopped an express train. He had had no application to him to put a boy in the cabin to help the signalman to do the booking. Mr. C. B. Byles, signalling superintendent, explained the system of signalling adopted on the electric system, the fundamental principle of which was a duplication of safeguards, and at any failure the signals got into a position showing safety. The Coroner, in summing up, said that the magnitude of the disaster should not influence the verdict of the jury. Nothing had come out in the enquiry to show that the machinery provided by the railway company was at fault. The only thing that it was suggested had been defective was the lock, and that was an extra precaution so as to inform the signalman whether the points were in order or not. The signal machinery was simply perfect if those in charge of it only obeyed what it said to them in dumb language. But in this case the signalman lost his head, he got hold of a green flag and waved on the train. The jury would have to study the rules and say whether he did right. The evidence of the other signalman was that it was against all rules and regulations, and the jury would have to say whether that was the prime cause of the disaster. They would also have to consider the conduct of the motorman. He suggested to the jury that the motorman should have disregarded the signal given by the signalman. If they found these men had been negligent they would have to say whether their conduct was censurable or culpable. Before they were satisfied that they were culpable they would have to find that these men had acted recklessly and without caring what the consequences were.—The jury found that the accident was caused by a mistake on the part of the signalman Boote and the

Digitized by Google

driver Rimmer, through an error of judgment, censurable but not criminal. They recommended the abolition of facing points, that motor guards should be made acquainted with the working of motors, and that signalmen and drivers should be periodically examined to test their knowledge of the rules.—Counsel for the company intimated that the company will not dispute civil liability for the accidents.

LIGHTING AND GENERAL.

Wednesbury.—Current is now to be supplied to consumers by slot meters at the rate of 4d. per unit.

Burrelton.—A committee has been appointed for the purpose of obtaining a telephone call office for the village.

Willington.—The Durham Electric Power Distribution Co. are applying for a provisional order for Willington.

Ryde (Isle of Wight).—The accounts of the Ryde Electric Lighting Co. for the year ending December, 1904, show a profit of £62.

Dunfermline.—The Fife Electric Power Co.'s generating station at Townhill, Dunfermline, was formally opened on the 15th inst.

Brandon.—The County of Durham Electric Power Distribution Co. intend to promote a provisional order for lighting in the Brandon district.

Worthing.—An inquiry has been held into the application of the Town Council for sanction to borrow £3,300 for electric lighting purposes.

Chatham.—A draft agreement with the Kent Electric Power Co. for making the trench in the streets for the company's cables has been approved.

Horncastle.—Permission has been granted the General Post Office to erect an overhead line of telephone wires from Horncastle to Woodhall Spa.

Canary Islands.—In consequence of the recent breakdown of the Canary Islands cable, the Spanish Press very strongly recommends the laying of a second cable.

Cleckheaton.—An inquiry has been held into the District Council's application for sanction to borrow £4,000 for the purposes of the electricity undertaking.

University College, London.—The courses of instruction in mechanical, civil, municipal, and electrical engineering begin on Tuesday, Oct. 3. Full particulars appear in another column.

Manchester.—The lord mayor (Sir T. Thornhill Shann) on the 14th inst. opened an exhibition in the Drill Hall, Wilmslow, designed to illustrate the various uses to which electricity may be put.

London Gazette.—The partnership between Frederick William Rutton May and Edwin George Kennicott Calder, electrical engineers, 4, Newington-causeway, London, has been dissolved by mutual consent.

Ryton.—The Urban District Council have consented to the application to be made by the County of Durham Electrical Power Distribution Co. for a provisional order authorising them to come into the Ryton District.

Scarborough.—The Town Council propose to purchase electrical plant, in order to replace manual labour in stone-breaking, gravel screening, and other work. The saving of ½d. on the rate is expected to result from this move.

Lowestoft.—The Electric Lighting Committee's last report shows that during July 12 new consumers have been connected to the mains, representing 338 8-c.p. lamps. There are now 639 consumers, representing 32 119 8-c.p. lamps.

West Auckland.—We understand that the Cleveland and Durham Electric Power Co.'s tender, of 37s. 6d. per lamp inclusive of all costs, is under favourable consideration. A parish meeting has decided in favour of the proposal by a large majority.

General Post Office Exhibit.—The General Post Office will at the electrical exhibition at Olympia next month show their complete loan exhibit illustrating the growth of the electric telegraph, which was displayed at the recent St. Louis Exposition.

Charing Cross, West End, and City Electricity Supply Co.—The directors have declared an interim dividend on the ordinary shares at the rate of 5 per cent. per annum for the half-year ended June 30, 1905. Warrants will be posted on the 15th inst.

South Metropolitan Electric Light and Power Co.—The transfer register of shares of this company will be closed from 18th to 31st inst., both days inclusive. The interim dividend to June 30 upon the 7 per cent. cumulative preference shares is payable 31st inst.

Dundee.—The electric lighting of the reading-room, free library, and art galleries is being considered, and the suggestion has been made that, instead of the electric current being generated on the premises as is done at present, the town's supply should be used.

Dumbarton.—The Electric Supply Corporation have ordered the mains for Dumbarton. At the next meeting of the Town Council it will be moved that provision be made to put in mains in the principal streets for the purpose of providing these streets with electric light.

Electro-peat Coal.—A plant for the manufacture of electro-peat coal has now been erected at Kiberry Bog, near Athy, co. Kildare, upon the estate of the Duke of Leinster, and will be in operation before the end of the present month, when the fuel is to be placed upon the market.

Sale of Plant.—The South Shields Guardians offer for sale a storage battery. Offers, in writing, should be delivered at the office of Mr. J. W. Coulson, clerk to the Guardians, by Sept. 1 next. Particulars of this and of a sale of two sets of triple-expansion engines, 1,750 h.p., will be found in another column.

Mather and Platt.—After transferring £30,000 to reserve (making it £230,000), the directors, in their report, recommend a further dividend of 3½ per cent., together with a bonus of 3 per cent., making a total distribution of 10 per cent. for the year ended June 30, and leaving a balance of £21,238 to be carried forward.

Yarmouth.—Nineteen applications for electric light on the route of the Gorleston and Southtown tramway have been received, which, if granted, will produce an estimated revenue of £130. Cables are to be laid from the Half-Way House, through High-street, to the Lowestoft-road terminus, at an estimated cost of £530.

Removal.—Messrs. Knight and Co. inform us that in consequence of the great increase in their business they have removed to much larger and more commodious premises which have been specially built for them at 227 to 239, Tooley-street, S.E., where in future their business will be carried on under the style of Chas. Knight and Co., Limited.

Special Work.—We are informed that the London electric firm of George-street, Croydon, make a speciality of direct-current dynamo and motor repairs and rewindings, having made special arrangements for the rapid execution of such work. A recent job for the complete renewal of a 10-kw. commutator has been done by this firm in two days.

Correspondence Classes.—Particulars will be found in another column with regard to the system of teaching electrical and mechanical engineering science by correspondence, exercises, drawings, and instructions, successfully carried on by Prof. Jamieson, at 16, Roslyn-terrace, Kelvinside, Glasgow. We note that correspondents may enrol at any stage and time.

Oswestry.—The Postmaster-General has informed the Council that he had requested the National Telephone Company to provide a direct circuit between their exchange at Oswestry and the Post Office trunk exchange at Wrexham, and this should meet Oswestry's requirements. He could not open a Post Office trunk exchange at Oswestry, nor could he undertake to extend the boundaries of the Wrexham exchange area, in which Oswestry was situated.

Aberaron.—The Council and the South Wales Electrical Power Co. are corresponding with regard to the terms upon which the Council would be prepared to allow the company to run their power mains in the district. They propose to pay the Council a sum equal to 2½ per cent. of the total received for energy supplied, provided that the maximum payment of £50 per annum should not commence until the beginning of the third year's supply. The Council desire the £50 should begin to run from the beginning of the second year.

Cardiff.—Mr. Arthur Ellis, manager of the electric lighting department of the Cardiff Corporation has reported to his committee that he had been asked to quote for a supply of electric current to the Great Western Railway Co., who proposed to use the town supply not only for lighting but for all power purposes in their sidings between Roath and Canton. About 1,600 h.p. would be required for motors. At present the company are using nearly a quarter of a million units, but this will be greatly increased in the future. The Council decided to offer the same terms as to the Ely Paper Works.

Agencies.—Mr. Norman Hamilton has opened business at 19, Waterloo-street, Glasgow, as agent (in Scotland) for Thomas Parker Limited, Wolverhampton, Kelvin and James White, and Jessop and Appleby Bros.—Messrs. Zschocke's Engineering Co., Kaiserslautern, Palatinate, have appointed Messrs. T. Sugden Limited of 180, Fleet-street, London, E.C., as sole agents in Great Britain and Ireland for Zschocke's patent water coolers, blast furnace gas purifying and similar plants. Messrs. Sugden have a branch office in Cardiff and are represented in Birmingham, Lancashire and Yorkshire, Newcastle, Glasgow, Llanelly, and Belfast, etc.

Taunton.—The following notices of motion have been tabled: (1) that, in consideration of the electric light works having a deficit of over £60 on last year's working, and, nothing having been put by for depreciation (over the small sum for sinking fund), which according to the committee's own showing on the boiler it is proposed to sell is 5½ per cent.—£220 off £376, it being now worth £156—no further loan should be sanctioned until sufficient is charged to the consumer to pay working expenses and meet such depreciation; (2) that the resolution passed at the special meeting of the Council on July 21, 1905, to sanction a loan of £5,000, be rescinded.

India.—*Indian Engineering* says the Railway Board has sanctioned the fitting of the two saloon carriages of His Excellency the Commander-in-Chief, the manager's saloon carriage, and six first and second class carriages for service on the Karachi Quetta run with Stone's batteries for supplying electric power for fans and light on the North-Western Railway. An estimate for the extension of electric lighting in Government House, Madras, is under consideration. The cost works out to Rs.34,216, and a provision of Rs.35,000 has been made in the budget for the work. The roadmaking to the new powerhouse for the proposed Mussoorie hydro-electric scheme is nearly complete. About 20 firms up to the present have evinced a desire to tender, but some of them may change their minds. There is plenty of time yet.

Stock Exchange.—The Stock Exchange Committee have appointed Aug. 23 special settling day for County of Durham Electrical Power Distribution Company's 40,000 ordinary shares of £5 each, £2 paid, Nos. 10,001 to 50 000, and 30,000 5 per cent. preference shares of £5 each fully paid, Nos. 20,001 to 50 000; and have ordered the undermentioned securities to be quoted in the official list: County of Durham Electrical Power Distribution Company's 40,000 ordinary shares of £5 each, £2 paid, Nos. 10 001 to 50 000 and 30,000 5 per cent. preference shares of £5 each fully paid, Nos. 20,001 to 50 000; Metropolitan District Railway Company's further issue of £100,000 4 per cent. perpetual debenture stock. Application has been made to allow South Staffordshire Mond Gas (Power and Heating) Company's 33,346 ordinary shares of £10 each, fully paid, Nos. 1 to 3,334 and 4,001 to 34,012 (renewed special application), to be quoted in the official list.

Catalogues.—The 1905 edition of Verity's catalogues contains following sections: Department I.—(P) plant and alternating-current machinery; (M) continuous-current dynamos and motors; (C) main switches, switches, and controllers; (L) arc lamps. Department II.—(A) accessories; (S) wires, cables, and supplies; (R) heating appliances; (B) bells and telephones. Department III.—(A) ornamental fittings; (B) plain fittings; (C) fittings, accessories. They will be forwarded post free to our readers from Verity's Limited, 31, King-street, Covent Garden, London; 3, Queen-square, Bristol; Hardman-street, Deansgate, Manchester; 33, Highbridge, Newcastle-on-Tyne; 40, Bath-street, Glasgow.

King's Lynn.—At last week's meeting the engineer reported that since the previous meeting applications had been received for 105 additional lamps of 8 c.p. or equivalent, making a total of 21,384 from private consumers, and that there are two additional consumers, making a total of 525. He also reported that he had asked the General Electric Co. to quote for apparatus for the switch-board in connection with the generator. An offer of £60 from Messrs. Fielding and Platt for the gas-producer as it stands was accepted. The following report was submitted: Units generated, June 1905, 25,065 (1904, 23 252); total units sold to private consumers (light and power), 15,823 (13,759); units sold at lighting rates, 4,820 (4,102); units sold at power rates, 11,003 (9,657); cost of fuel, stores, repairs, and wages at station, £111. 10s., £113. 2s.; cost per unit generated, 1·0675d. (1·1683d.); wages of lamp-lighters and outside staff, £16. 13s. 7d. (£20. 8s. 11d.).

Wisbech.—Mr. Southwell has been appointed chairman of the Electric Lighting Committee for the ensuing year. The Local Government Board have informed the Council with regard to the application for sanction to borrow £25,000 for electric lighting purposes, that the Board of Trade are not prepared to give their consent under Section 11 of the Electric Lighting Act, 1882, to the proposed agreement between the Town Council and the National Electric Construction Co. They added that if the Town Council desire to raise a loan for the purpose of providing an electric lighting undertaking, and then to transfer the undertaking for a period of years to a company, the Council should seek further powers enabling them with the consent of and by deed to be approved by the Board of Trade to transfer their powers, duties, and liabilities subject to such exceptions and modifications as may be specified in the deed. The Board of Trade would then be prepared to consider an application for their consent to a deed of transfer on the above lines.

Doncaster.—An inquiry has been held into the application of the Corporation for powers to borrow a further sum of £7,172 for the extension of their electrical undertakings. The Town Clerk (Mr. R. A. H. Tovey) stated that although the Corporation had been reluctant to spend over and above what they had authority to spend, they had been compelled to spend a certain amount of money on the extension of their tramway system. It was necessary that they should have sufficient energy to deal with the special race week traffic. Last year they had managed to get through with their present plant. To avoid the risk of breakdowns they had decided to put down another boiler and engine at an estimated cost of £2,250 for the machinery. Then the foundations were estimated to cost £200, the steam pipe and exhaust, switchboard, etc., making a total of £6,420. The former cost of work done had exceeded the estimate by £11, and sundry expenses since had amounted to £741. They hoped to be able to have the additional energy ready for generation for the September race week. The tramways were owned by the Corporation. In Doncaster they had one power station for both lighting and traction. In 1901 the Corporation had generated 90,000 units, last year they had generated 973,266 units. That had been largely due to the tramways undertaking, but the demand for electric lighting had also increased. The profit made over and above expenses during the past year had amounted to £4,007, less interest and redemption, or £850 with interest and redemption. The average charge made by the Corporation for electrical energy was 4·4d. per unit, 2d. for power and 1½d. per unit for tramways. Private consumers were charged 2d. per unit for the first 5,000, 1½d. per unit for the second 5,000, and 1½d. per unit for the third 5,000.

Parliament.—The following private Bills have received the Royal assent: Aberdeen Urban District Council (changed from Aberdare Tramways), Accrington Corporation, Andover Lighting and Power, Baker-street and Waterloo Railway, Birmingham Corporation, Blackpool Improvement, Bolton Corporation, Bootle Corporation, Bristol Corporation, Central Electric Supply, Charing Cross, Euston, and Hampstead Railway, Chelsea Electricity Supply, Colne Corporation, County of London Electric Supply Co., Croydon Corporation, Dublin United Tramways, Ealing Corporation, Edgware and Hampstead Railway, Gosport and Fareham Tramways, Great Northern, Piccadilly, and Brompton Railway (No. 1), Great Northern Railway, Great Western Railway (Additional Powers), Great Western Railway (New Railways), Halifax Corporation, Hastings Tramways, Littlehampton Urban District Council, Liverpool Corporation, Llandrindod Wells Urban District Council, London and North-Western Railway, London County Council (General Powers), London Southern Tramways, London United Tramways (Extension of Time), Loughborough Corporation, Mansfield Corporation Metropolitan and Great Central Railway Companies, Metropolitan District Railway, Metropolitan Electric Supply Co. (Acton District), Metropolitan Electric Supply Co. (Various Powers), Metropolitan Electric Tramways, Metropolitan Railway, Mexborough and Swinton Tramways (Extension of Time), Morley Corporation, Newcastle-upon-Tyne Corporation, North-Eastern Railway, North-East London Railway, North Metropolitan Electric Power Supply, Nottingham Corporation, Oldham and Saddleworth District Tramways, Rhondda Urban District Council, Rhymney Railway, Rotherham, Maltby, and Laughton Railway, Sandgate Urban District Council, Shepton Mallet Gas Co. (Electric Lighting), Shropshire, Worcestershire, and Staffordshire Electric Power (changed from Shropshire and Worcestershire Electric Power), Skegness Water, Southampton and Winchester, Southend and Colchester Light Railways, South Lancashire Tramways, South Wales Electrical Power Distribution Co., Stockport Corporation, Swansea Corporation, Tralee Urban District Council, Tyneside Tramways and Tramroads, Ulster and Connaught Light Railways (changed to Newry, Keady, and Tynan Light Railway), West Cumberland Electric Tramways (Extension of Time), Weybridge and Walton-upon-Thames Electric Supply, Whitby Urban District Council, Whitechapel and Bow Railway, Wigan Corporation, and Woolwich Borough Council. The following provisional orders confirmation Bills have received Royal assent: Electric lighting provisional orders (Nos. 1 to 9), Bury (Rural), Conway, Golbourne, Haydock, Hipperholme, Little Lever, Southall-Norwood, Spalding, Whitwood, and Whitworth; Ballaghaderren; Woolwich; Denny and Dunipace, Grangemouth, Inverness, Pollokshaws, Renfrew, Rutherglen, and Uphall; Andover, Barnsley, Hessle, Litherland, Little Hulton, Penmaenmawr, Ravensthorpe, Stratford-upon-Avon, Surbiton, and Tewkesbury; Barnet, Brockenhurst, Farnham, Gosport and Alverstoke, Houghton-le-Spring, Lichfield, Ludlow, Lytham, St. Alban's, and Ware; Bishop's Stortford, Dover, Hemsworth, Marlborough, Tottington, and Woking; Airdrie, Coatbridge, and Cults and District. Tramways orders confirmation (Nos. 1 and 2), Bradford, Gorton, Keighley, Leeds, Liverpool, and Pudsey; Colchester, King's Norton and Northfield, Luton, Portobello and Musselburgh, and Southampton. Also Scotland: Paisley District Tramways and Wemyss Tramways.

Tottenham.—The agreement which has just been entered into by the Tottenham District Council for the transfer of its powers under its provisional order (obtained in 1902) to the North Metropolitan Electric Power Supply Co. provides that the company shall before Oct. 1, 1906, carry out all necessary works to give a full and proper supply of electrical energy within the compulsory area, and also in certain additional streets. Further distributing mains are to be laid by the company on the requisition of the Council, or of owners or occupiers, and in any notice under Section 25 of Electric Lighting Clauses Act, 1899, the company shall not specify any sum exceeding 8 per cent. upon the cost. Before commencing the works, the company undertakes to submit to the Council full particulars of the system of supply and distribution which it proposes to adopt for the reasonable approval of the Council, the energy to be distributed under the provisions of the order solely from sub-stations or feeding points within the district. The company agrees to reimburse the Council the expense it was put to in obtaining the order and in opposing the company's Bill, and also the amount which, with the consent of the company, or under an order of a court of law, the Council may pay to its late consulting engineer, together with the costs properly incurred by it in defending, at the request of the company, any action brought by him in connection therewith. The charges for the supply of energy are to be: public lighting—2d. per unit between dusk and midnight and 1d. per unit between midnight and dawn, or at the rate of 1½d. per unit for lamps kept alight from dusk to dawn, provided that the Council enter into a contract for the lighting of not more than 110 lamps of an average consumption each of 600 watts for 10 years; private lighting—6d. per unit for the first 100 hours maximum demand, and 2d. per unit for subsequent consumption, or, in the alternative, a flat rate of 5d. per unit; power or heating (if separately metered)—4d. per unit for the first 100 hours maximum demand if 5 h.p. is not exceeded, and 1d. per unit for subsequent consumption. Energy supplied to the Council for public purposes other than street-lighting is to be charged at 10 per cent. less than to private consumers. At the expiration of the first and every subsequent period of seven years, the Council can require a revision of these rates, and in the event of a difference the terms are to be settled by reference to arbitration. If the Council erects a generating station in connection with its refuse destructor, it can compel the company to purchase the energy at the price of 1·43d. per unit metered at the switchboard, but the cost of laying the necessary mains to the company's sub-stations or feeding points must be borne by the Council. At the end of each year after the expiration of 10 years, the company is to pay the Council half of the net profits in excess of a sum of 5 per cent. upon the amount expended by the company in the area of supply, but if the net profits in any previous year have not amounted to 5 per cent., the company will be entitled to make good the deficiency out of the receipts for any subsequent year before the net profits are ascertained. The Council has power, upon giving six months' notice, to require the company to sell to it the undertaking (*a*) at the end of 10 years or of a further period of five years upon paying the capital expended, and a sum equal to one-tenth of that amount, and also refunding the sum paid by the company as the costs of the Council in obtaining the order and in opposing the company's Bill, etc.; (*b*) at the end of 1930 and upon the expiry of every subsequent period of 10 years on the same terms with the exception that the Council would not have to pay a sum equal to a tenth of the capital expenditure; and (*c*) at the expiration of 42 years upon the terms mentioned in Section 2 of the Electric Lighting Act, 1888, the company to hand over on the completion of the purchase the undertaking in good condition and repair. If the Council elects to purchase at the end of 10 or 15 years it will be bound to take its supply in bulk from the company. If it exercises the option on Dec. 31, 1930, or at the expiry of any subsequent period of 10 years, it can call upon the company to supply in bulk. The Council consents to the company supplying electrical energy for power purposes to any company, body, or person within the Council's district, but consumers using less than an average of 30 units per day throughout the year, and whose premises are less than 440 yards distant from the distributing main laid by the company under the order are exempted from the operation of this clause. After the determination of the agreement, the company will pay the Council 5 per cent. of the gross receipts to be derived from the supply of electrical energy for power within the district.

PROVISIONAL PATENTS, 1905.

AUG. 3.

15871. An improved box for enclosing switches, fuses, or the like. George Owen Donovan, 126, Chester-road, Erdington, Birmingham.

15890. Improvements in or relating to switches for electrically driven motors. John Stratton and Ernest Alexander Claremont, Throstle Nest House, Old Trafford, Manchester. (Complete specification.)

15910. Improvements in vapour electric apparatus. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

AUG. 4.

15940. An improved type of four-way disconnecting street-box for the distribution of electricity by single, triple-concentric, or three-core mains. Thomas Henwood, 14, Pelham-square, Brighton.

15945. Novel or improved electromagnetic motor. Henry Ramsden Mortell and Leo Liberiate Mortell, Gough-chambers, Savile-street, Hull.

15969. Improvements in coin-freed apparatus for the supply of electric current. John Hikeley and the Newcastle-upon-Tyne Electric Supply Company, Limited, 46, Lincoln's-inn-fields, London. (Complete specification.)

15993. Improvements in electrical ignition apparatus. Harold Ernest Copp, 77, Colmore-row, Birmingham.

15996. Improvements in or relating to globes or the like for electric lamps or other purposes. Ernest Bohm, Birkbeck Bank-chambers, Chancery-lane, London.

16008. A method of increasing the capacity of electric accumulators. Max Roloff, 18, Southampton-buildings, Chancery-lane, London.

16024. Improvements in and relating to telephone office systems and to methods of establishing connections therein. Clement Lean, Thanet House, Temple Bar, London. (Deutsche Telephonwerke, R. Stock and Co., G. m. b. H., Germany.) (Complete specification.)

AUG. 5.

16057. Improvements in and relating to magneto-ignition apparatus for use with internal-combustion engines. Josef Gawron, 51, Deansgate-arcade, Manchester. (Date applied for under Patents Act, 1901, Aug. 6, 1904, being date of application in Germany.) (Complete specification.)

16063. Improvements in rheostats, controllers, and starting switches for electro motors. John Richardson Craig, jun., 26, Renfield-street, Glasgow. (Complete specification.)

16072. Improvements in or relating to electric cells. Alfred Loebl, 111, Hatton-garden, London. (Complete specification.)

16075. Improved means for supplying and cutting off currents of high potential to and from conducting lines. Siemens-Schuckertwerke G. m. b. H., Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Feb. 23, 1905, being date of application in Germany.) (Complete specification.)

16079. Improvements in or relating to interrupters for making and breaking electric circuits. Albert Lewis Davis, 70, Chancery-lane, London. (Complete specification.)

16080. Improvements in or relating to interrupters for making and breaking electric circuits. Albert Lewis Davis, 70, Chancery-lane, London. (Complete specification.)

16083 Improvements in electric telegraph apparatus for transmitting indications corresponding to a transmitter handle. Joseph Robinson, 1, Queen Victoria-street, London.

16088. Improvements in or relating to means or apparatus for supplying electric current to telephonic apparatus. Edward Alfred Graham, 46, Lincoln's-inn-fields, London.

AUG. 8.

16123. An improved galvanic battery. Richard Joseph Crowley and Frederick Fitz Payne, 27, Chancery-lane, London.

16134. Improvements in or relating to electric furnaces. Charles Haswell, Arthur John Cridge, and Andrew Bashforth, 111, Hatton-garden, London.

16143. Improvements in and relating to electro-capillary recording apparatus. Axel Orling and Frederick William Corby, 61, Chancery-lane, London.

16179. Improvements in or connected with electrical ignition gear for internal-combustion engines. Frederick Richard Simms, 4, South-street, Finsbury, London.

AUG. 9.

16221. Improvements in or relating to the mounting of electricity conducting rails. La Société Anonyme des Manufactures des Glaces et Produits Chimiques de Saint-Gobain, Chauny et Cirey, 46, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Oct. 7, 1904, being date of application in France. (Complete specification.

AUG. 10.

16249. Improvements in the method of constructing and laying underground mains for the distribution of electricity. Percy Nicholas Hooper and Alexander Duckham, Phœnix Wharf, West Ferry-road, Millwall, London.

16273. Improved means for coupling conduit pipes as used in the laying of electric wires and for like purposes. Albert Powell, 55, Market-street, Manchester.

16292. Improvements in or relating to starting devices for electric motors and the like. Martin Kallmann, 111, Hatton-garden, London. (Complete specification.)

16296. A combined advertisement column, fire-alarm, and police telephone. Carl Anton Andreasen, 73, Cheapside, London.

16300. Improvements in enclosed electrical machines for effecting the ventilation thereof. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens-Schuckertwerke, G. m. b. H., Germany.) (Complete specification.)

16301. Improvements in electric arc lamps. Walter Claude Johnson and Mads Peter Thomsen, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

16303. Improvements in alternating-current motors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

16304. Improvements in dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States).

AUG. 11.

16324. A new or improved electrically-controlled circuit breaker. Ernest Turner, 213, Second-street, Trafford Park, Manchester.

16357. Improvements in arc lamps. André Blondel, 111, Hatton-garden, London. (Complete specification.)

16358. Improvements in or relating to the electrical operation of typesetting, typewriting, and like machines. Alfonso de Gessler, 111, Hatton-garden, London.

16373. Improvements in or connected with electric switches. Karl Schmahl, jun., 173, Fleet-street, London.

16397. New or improved disengaging mechanism for the controlling devices of shunt-circuit arc lamps. Oscar Efrém and August Sidler, 31, Bedford-street, Strand, London. (Complete specification.)

16398. Improvements in alternating-current motors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.) (Complete specification.)

AUG. 12.

4166A. Improvements in induction coils. Robert Bines, 46, Lincoln's-inn-fields, London. (Date applied for under Rule 5 of the Patents Rules 1905, Feb. 28, 1905.) (Complete specification.)

4167A. Improvements in telephone systems. Robert Bines, 46, Lincoln's-inn-fields, London. (Date applied for under Rule 5 of the Patents Rules 1905, Feb. 28, 1905.) (Complete specification.)

16404. An improved system of distributing electric power for traction purposes, regulated by signals and the like. Thomas Hackett Wright, 285, Upper Brook-street, Manchester.

16425. Improvements in gas and electric lamps or fittings. George Arthur Walker, 7, Staple-inn, London.

16434. Improvements in electric dental engines. Ernst Klapproth, 4, South-street, Finsbury, London. (Complete specification.)

16435. Improvements relating to transmission systems for wireless telegraphy. Simon Eisenstein, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Aug. 31.

1904.

16751. Galvanic batteries. Pörscke and Wedekind.

17059. Electromagnetic controlling devices especially applicable for use in automatic weighing apparatus. Darrah and Hackett.

17534. Construction of mechanical ear for electric trolley wires or the like. Phillips.

17601. Rotors of alternating-current machines. Zani and Dick, Kerr, and Co., Limited.

18937. Means and appliances for operating electrolytic cells. Hargreaves.

19574. Electric motor control systems. British Thomson-Houston Company, Limited. (General Electric Company.)

19589. Electric-magnetic mechanism, particularly applicable to railway signalling apparatus. British Thomson-Houston Company, Limited. (General Electric Company.)

20413. Hangers and ears for electric conductor wires. Heap, Bailey, Heap, Richardson, Billington, Haydock, Jones, and Brierley.

Digitized by Google

20552. Dynamo-electric machines. British Thomson-Houston Company, Limited. (General Electric Company.)

20609. Electric meters and measuring instruments. British Thomson-Houston Company, Limited. (General Electric Company.)

21242. Electric arc lamps. Gross.

21640. Apparatus for wireless telegraphy. Marconi's Wireless Telegraph Company, Limited, Berry, and Ewen.

21641. Safety devices in connection with radio telegraphic transmission circuits. Marconi's Wireless Telegraph Company, Limited, Berry, and Ewen.

21722. Rail joints and electrical bonds connected therewith. Radford.

21729. Swivelling coupling for electric cables. Phillips and Parkin.

21892. Electric arc lamps. Lewis.

21895. Electric telegraphs. Siemens Bros. and Co., Limited, and Grimston.

27246. Electrical measuring instruments. Siemens Bros. and Co., Limited, and Holmes.

1905.

1919. Brush-holder for dynamo-electric machines. Burke.

2426. Electrical resistances. Leonard.

2816. Automatic lubrication of trolley wheels for overhead system of electric traction. Bedford.

9219. Coherers. Magini. (Date applied for under International Convention, May 8, 1904.)

11605. Retransmitting and reinforcing telephone currents on lines, also used for telegraphic purposes, or otherwise liable to have currents of relatively low frequency passing over them. Kingsbury. (Western Electric Company.)

NOTES.

New Publication. — "Wireless Telegraphy and Hertzian Waves," by S. R. Bottone. (London: Whittaker and Co. 3s.). The author presents the public with an excellent treatise, chiefly elementary, of the phenomena of electric waves, and their use for telephonic communication. Students should find it a useful guide.

Personal.—At the funeral of Mr. W. E. Langdon on the 17th inst., the Council of the Institution of Electrical Engineers was represented by Mr. W. M. Mordey, vice-president), Mr. W. H. Patchell (vice-president), and Mr. G. C. Lloyd (secretary). Sir William Preece, who is absent in South Africa, was represented by his son, Mr. A. H. Preece.

Wireless Telegraphy.—In consequence of forest fires, floods, and the atmospheric conditions, it has been found extremely difficult to maintain telegraphic communication in the regions of the Lower Yukon, Alaska, and the Government is preparing to instal a wireless system. Experiments, which have so far proved successful, are being carried on.

Junior Institution of Engineers.—Vol. xiv. of the *Record of Transactions* contains the papers read during the twenty-third session, with the discussions, and an account of the visits of inspection made by the members. There is also a lot of information upon the history, membership, and finance of the institution, which will be found interesting and useful for reference.

Natural Gas Production.—The approximate value of the natural gas produced and sold in the United States, as reported to the United States Geological Survey, is given as about £8,000,000. Pennsylvania, Ohio, Indiana, and Kansas were the most prolific States, the products from the first-named representing nearly half the total. These figures do not take into account the natural gas produced in Canada and consumed in the United States.

Rubber.—The report of the British Consul at Para gives some information upon the practice of adulterating rubber. It was observed that a latex obtained from a tree entirely different from the "Heveas" is employed for this purpose, and even as a substitute for rubber altogether. The demand for rubber has led for some years past to an increase of adulteration, the plant used being plentiful in the Para district. These products are apparently of a tolerably serviceable character, and the substituted plant (the "Tapurú") is fruitful of growth, but the material is rather less elastic than the genuine article.

Cable-Laying.—The cable steamer "Colonia," which started on Saturday to lay the Commercial Cable Company's fifth Transatlantic cable from Canso, N.S, to Waterville, Ireland, appears to be in rather a bad way. The shore end of the cable was successfully dropped, and the steamer then put to sea, when the weight of the cable and the strong tide drove her on the rocks almost at high water. An unsuccessful attempt to float the "Colonia" was made on Monday, but the following day she was got off, the holes in her having previously been closed. It is expected that she will proceed to the Halifax Government Dock.

Telegraph Poles.—An inquest was held at Paddington last week on a telegraph wireman who succumbed to injuries received through the falling of a pole which he was repairing. The pole fell in consequence of the cast-iron base breaking. Evidence showed that the pole was carrying much less than its "breaking weight," and that the flaw could not have been detected by external examination. The end of the steel pole was some 2ft. above the ground line, so that the cast-iron base took all the stresses. The jury returned a verdict of accidental death, but suggested that the steel tubes should extend through the iron base into the ground. This is the procedure followed in all tramway work, where the cast-iron base is used for ornament only.

The Franklin Bicentenary.—It will be 200 years on Jan. 17 since Boston, U.S.A., witnessed the birth of Franklin, and it is but fitting that the American Institute of Electrical Engineers, in conjunction with the old-established New York Electrical Society, should take a prominent part in the celebrations which will doubtless mark the event. Franklin's fame as a scientist has been somewhat obscured by his celebrity as a politician, and, saving for his invention of the lightning rod—which is perhaps more correctly attributed to Procopius Diviss—he is remembered rather as a founder of the Great Republic than for his scientific research. Yet he deservedly holds a high place in the annals of science as a pioneer of the modern uses of electricity, and the fact that he had not a little part in the severance of our Transatlantic cousins from the Mother Country will not deter electrical men on this side from participating, at least in the spirit, in the recognition of his valuable efforts in the cause of science.

Telephonic Intercommunication.—An agreement is announced between the Post Office and the National Telephone Company by which intercommunication will be afforded over the Newcastle area. In the case of a call involving the use of both systems, a charge of 1d. per message will be payable by the person originating the call. Besides the four exchanges in the Newcastle proper area, the Post Office has 10 exchanges in the adjoining districts. The rates of subscription to the Post Office system are £3 per annum and 1d. for each call, whether involving the use of one or both systems; or £7. 10s. per annum (plus £1. 5s for each additional quarter mile of wire beyond a radius of half mile from the nearest exchange), with a charge of 1d. for each call involving the use of the company's system. This arrangement between the two undertakers is of interest as showing that the authorities at St. Martin's-le-Grand have finally decided upon co-operation in regard to the oldest of their telephone stations, which was designed by Mr. A. W. Heaviside.

Electric Lighting in New York. — The New York Edison Company has come in for a good deal of criticism from the American Press and public in regard to the conditions of its service, but the reduced charge for current of 5d. per kilowatt-hour enforced by the Government at the instance of the recent committee of investigation has not deterred the company from continuing its policy of supplying consumers free with arc lamp carbons and renewing all incandescents, although the reduction in the price of current is estimated to represent a loss of £200,000 a year. This gratuitous supply of lamps is a factor which should be borne in mind when instituting comparisons between the rates prevailing in America and in this country, and it is a practice that we should like to see imitated here. It would do better justice to electricity as an illuminant, and the undertaker would probably find his additional outlay and cost of supervision well repaid in the long run, as seems to have been the case with the New York Edison people.

Leasing of Provisional Orders.—The Frome Urban District Council, having obtained a provisional electric lighting order, came to the conclusion that the best policy would be to lease the undertaking, and negotiations were accordingly entered into with Edmundson's Electricity Corporation, by which the latter, having laid down the system with capital provided by the local authorities

Digitized by Google

would carry on the concern for a period not exceedin 25 years on agreed terms. To carry this arrangement into effect the Council find it necessary to apply for a supplementary provisional order, as, by a recent decision of the High Court, it was laid down that the prohibition against the assignment of a provisional order without express powers applies also to leasing. The latter type of transaction does not, perhaps, lend itself so readily to "trafficking" as the former, but it is just as well to close up the loopholes, and to make it clear that the local authorities are still responsible for the due carrying out of obligations of the order in spite of leasing the same.

Electric Lighting versus Gas.—Another addition to this controversy, and to the misrepresentation which it has entailed, occurred at the half-yearly meeting of the Bristol Gas Company the other day. The chairman, in contrasting the cost of electric lighting with that of some 1,200 displaced gas lamps, gave the figures as £9,600 and £3,100 respectively. In a letter to the local Press Alderman Pearson, chairman of the Corporation Electric Lighting Committee, exposes the glaring error of this comparison. The £3,100 simply represents the cost of the gas consumed, while, as the chairman of the gas company must surely be aware, the sum charged for electric lighting includes the cost of standards, lamps, mantles, connections, renewals, and repairs. Not only this, but the amount comprises provision for interest and sinking fund, so that the further assertion of the gas company's chairman that "there was capital expenditure in addition" looks like adding insult to injury. A good deal more will be heard before the last word has been written on this familiar question, but meantime it is to be hoped that the opponents of electricity will have more regard for facts than has always been the case in the past.

Olympia Exhibition.—The many arrangements in connection with the approaching exhibition are nearing completion, and the prospects for a highly successful show are most promising. We understand that at their last meeting the committee decided, in order to encourage the use of electrical energy for cooking purposes, to offer substantial prizes for the best and most efficient cooking apparatus. It is proposed to award the prizes for (1) the best completely fitted kitchen and (2) for the best single apparatus. With the view of affording all manufacturers of cooking apparatus an opportunity of making suitable preparation for this competition, the executive committee have decided to accept exhibits for the prize cookery section up to and including Saturday, Oct. 14; the judging will take place during the last week of the exhibition. Forms of entry can be obtained on application to the organising managers of the Olympia Electrical Exhibition, 119, Finsbury-pavement, E.C. This is a step in the right direction, for anything which tends towards popularising cooking by electricity is deserving of every support, and, no doubt, all firms who make a speciality of electrical cooking apparatus will embrace this opportunity of bringing their specialities well to the front.

Trolley Wheels.—Report No. 23 (price, 1s.) of the Engineering Standards Committee deals with trolley wheels and wire, and after carefully considering the information placed at their disposal the committee have come to the conclusion that no attempt should be made to standardise any particular design or shape of trolley wheel. They have, therefore, confined themselves to recommending a groove of a certain section, but point out that in recommending this section as standard they are not restricting engineers to the use of any particular design of wheel, but are rather suggesting that the overhead work be so arranged as to permit the standard trolley wheel groove being employed. Regarding wire, it has not been deemed advisable to go further in the direction of standardisation than the recommendation of the minimum tensile breaking strength, which is 24 tons per square inch for the gauges of wire in general use. The following are the dimensions recommended as the section of the standard trolley wheel groove: width, 1⅜in.; depth, ¾in.; angle, 65deg. We trust that these standards will be adopted by trolley wheel manufacturers. The committee consists of Messrs. A. P. Trotter, F. C. Armstrong, J. Burbridge, Philip Dawson, F. F. Higginson, E. R. Hill, J. H. Rider, H. M. Sayers, A. M. Sillar, J. J. Steinitz, and A. H. Walton.

Electric Railway up Mont Blanc.—Our French contemporary *L'Industrie Electrique* gives particulars of a company for constructing an electric railway up Mont Blanc, which was registered in Paris in June last. The object of the company is the construction and development of a railway between the station of Fayet-Saint-Gervais and the top of the Goûter Needle, in conformity with the concession held by the company. In due course this line will be extended until it eventually reaches the summit of Mont Blanc. The concession for the construction of this extension is also held by the company. Other branch lines and extensions to subsidiary peaks are included in the company's powers, and may be made in due course. The capital of the company, however, is only 1,000,000fr., and we hardly think this sum, equal to about £40,000, sufficient for even the first part of the work contemplated, but under the articles of association the capital of the company can be increased at any of the general meetings of the shareholders. We notice that all the directors of the present company are French. The company takes over the whole of the preliminary work carried out by the previous society which obtained the concession for the construction of the line. Our contemporary gives no information as to how soon the work foreshadowed is to be commenced.

Heavy Tram Traffic.—The plaint of "A Would-be Passenger" which appeared in the daily Press the other day as to the difficulty of entering the London United Tramways cars at week-ends and holidays, especially on the Hampton Court line, lends support to his plea for the introduction of the queue system. Anybody who has stood at the Shepherd's Bush terminus on a Saturday or Sunday, to say nothing of a bank holiday, can testify to the scramble, sometimes approaching a free fight, for the privilege of travelling in the cars. The correspondent mentioned above states that he witnessed the wreckage of hats, the tearing of coats and dresses, and even the infliction of a severe wound. All this is an eloquent, if not very edifying, appreciation of the company's service, but much of the present inconvenience might be obviated by the introduction of the queue system, which has been found to work excellently at Blackfriars Bridge. The same writer also complains of the dangerous practice of starting the cars while people are endeavouring to mount them. The fact is that the large crowds at Shepherd's Bush often continue their attempt, regardless of the bell, to mount the cars after they are full up—another argument in favour of the queue system. Incidentally, this state of affairs affords further evidence that an efficient service creates new traffic. Before the London United Tramways laid down their system there was a horse service from Shepherd's Bush to Acton. No such grievances as the above were heard in those days!

Standard Telegraph Material.—The Engineering Standards Committee has issued its report (No. 16) regarding telegraph material. The committee (which consisted of

Digitized by Google

Messrs. J. Gavey, H. A. Kirk, H. Hartnell, Llewellyn Preece, F. Gill, T. Ireland, H. Jackson, J. Sayers, A. H. Howard, and F. Jacob) considered it inadvisable, in the present state of the industry, to make any attempt to standardise submarine or underground cables. They also considered it unnecessary to touch upon the question of standardising telegraphic or telephonic apparatus. Regarding copper conductors, the committee have formulated standards regulating the mechanical strength of the copper, resistance, specific gravity, and temperature coefficient. A variation of 2 per cent. is allowed in regard to both resistance and weight, and an additional allowance of 1 per cent. is made in respect of the resistance of tinned copper conductors. For the purpose of compiling the tables, a lay involving an increase of 2 per cent. in each wire (except the centre wire) for the total length of the cable is taken as the standard. The definitions are supplemented by tables of standard sizes for hard-drawn copper wire and of commercial annealed copper conductors. A valuable collection of definitions and specifications, with tables and diagrams, is given in relation to iron wire for the conducting line, for mechanical purposes, and for binding, arm-bolts, nuts and washers, stay swivels, truss and brace rods and truss tie, tie and brace bolts, stay rods and tighteners, insulator spindles, cup-holders (single and double), and tensile test-pieces. The price of the report is 10s. 6d.

Bombay.—The Indian Government has sanctioned the issue of a license to the Brush Electrical Engineering Company for the supply of energy for all purposes except traction. The area covers the city, town, and island of Bombay, but excludes Government buildings. The maximum rate which may be charged is Rs.20 for any quantity of energy for all purposes up to 40 units, and for each subsequent unit eight annas. A fairly wide range of systems is sanctioned, comprising: (1) (*a*) A continuous-current supply at a pressure not exceeding 230 volts between the adjacent conductors of a three-wire system; (*b*) a continuous-current supply at about 550 volts for power purposes where the approval of the local government is given. (2) (*a*) A low-pressure alternating-current three-phase supply at a pressure not exceeding 240 volts between phases and at a frequency of 50 complete periods per second. (*b*) A high-pressure alternating-current three-phase supply at about 500 volts and at a frequency of 50 complete periods per second for power purposes where the approval of the local government is given. (3) An extra high-pressure alternating current three-phase supply at about 5,000 volts between phases and at a frequency of 50 complete periods per second, the neutral point of the generators being, with the approval of the local government, connected to earth. The local government are at liberty to issue regulations dealing with these systems, and, as provided by the Indian Electricity Act, they may exercise their option of purchasing the undertaking after 42 years and at the end of each decade thereafter. The licensees may transfer the undertaking at any time with the consent of the local government.

A New Method of Damping Galvanometers.—A simple method of damping a galvanometer to a known and adjustable extent is described in the *Annalen der Physik* by Mr. W. Einthoven. It consists in connecting a condenser in parallel with the galvanometer. If a potential difference is applied to the terminals of the galvanometer when no condenser is present, and assuming that the inertia of the needle is negligible the deflection will instantaneously reach its steady value, but if a condenser of capacity, C, is in parallel with the galvanometer the deflection will gradually increase from zero to its steady value, A, along a logarithmic curve. If a is the value of the deflection t, seconds after the voltage is applied $a = A\left(1 - e^{-\frac{t}{w'c}}\right)$, where e is the base of the natural logarithms, and w' is the combined resistance of galvanometer, and supply circuit, or $w' = \frac{w_a\ w_i}{w_a + w_i}$ where w_a = resistance of supply circuit and leads and w_i = galvanometer resistance, $w'\,C = T$ is the time constant of the deflection and by increasing either w' or C the deflection can be delayed to any desired extent. The writer shows by means of examples that even when the inertia of the needle is not negligible it is possible to select a value for T, which shall just cause the limit between an oscillating motion and a periodic motion to be reached, and that the value of the capacity necessary for this gets less as the tension of the galvanometer support is increased. By means of a sub-divided (plug) condenser a convenient and exact adjustment of the degree of damping becomes possible, but the application of the method is obviously only practicable in the case of high-resistance galvanometers with short time of swing, such as would be used in the measurements of current changes of very short duration.

Lightning Arresters.—A patent has been granted to Messrs. Siemens Bros. relating to lightning arresters of the horn type, so arranged as to prevent excessive voltage in electric circuits. This is effected by utilising auxiliary sparking gaps, with resistances or self induction devices located in parallel with the main gap. Reference to the first diagram discloses an auxiliary sparking gap, 1, arranged in parallel with the main gap, 3, the auxiliary gap generally having the electrodes, *e'*, pointed, and placed in closer proximity to each other than the rounded main electrodes, *e*.

FIG. 1.

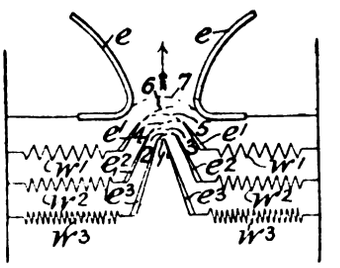

FIG. 2.

This plan permits of greater space in the main gap than hitherto, the arcs being formed progressively from 1 to 3, and arc 1 becoming immediately extinguished on the formation of arc 3. Reference to the second diagram shows the operation of the arrangement with a number of auxiliary sparking gaps in parallel with the main gap. The auxiliary gaps are at gradually increasing distances apart as they recede from the main gap, and the pointed formation also gradually diminishes, as does the strength of the corresponding resistances. The gaps are bridged by arcs in the order 1 to 7, as indicated in the second diagram. Lightning conductors are among the appliances which this arrangement is designed to improve.

A Large Bavarian Power Scheme.—An interesting opportunity of utilising water power in the Bavarian Alps has been reported upon by a Swiss engineer, Mr. Jeanjaquet, in conjunction with a German engineer, Mr. Schmick, of Darmstadt. If the scheme is carried through, it is estimated that sufficient electrical energy will be obtained from the water to drive the greater part of the Bavarian State railways. The idea is to utilise two lakes which are situated in the mountains near each other, but with separate watersheds. They each discharge into the River Isar, but by separate outlets. The lake which will be used as a reservoir is named Walchen. The surface of

Digitized by Google

the water in this lake is about 6½ square miles, and the maximum depth of the water in it is over 600ft. The height of the lake above sea-level is 2,635ft. The lake of Kochel, into which the water can be diverted, is about 660ft. lower, and the direct distance between the two lakes is only some 2,200 yards. A tunnel would have to be made through the hill which divides the two lakes. The scheme, however, goes further than this. The watershed draining into Lake Walchen is not a very large one, and would not provide the desired power regularly. A few miles south of this lake there is the River Isar, which in its upper reaches flows from west to east. The level of the river is considerably above that of the lake, and hence it is proposed to divert a certain portion of the water into the lake by means of another tunnel through the dividing hills. This water can then be stored in the lake, which will form a splendid natural reservoir. This, combined with the high fall obtainable, makes the scheme an exceedingly attractive one, and we trust that it will be sanctioned and the works constructed. The lower portion of the River Isar, between the point where it would be diverted into the lake and Munich, is exceedingly rapid, and contains a number of falls which have already been harnessed for industrial purposes. This scheme, however, could be so arranged as not to interfere with these, as the volume of water passing down the river would be rendered more uniform than at present in consequence of the storage reservoir described above.

Educational Science.—The subject selected for his address by Sir Richard Jebb, president of the Educational Science Section of the British Association, was "University Education and National Life." Sir Richard commenced by tracing the extension of university education during the Victorian era. Not only had Oxford and Cambridge opened their doors to the community in a much larger degree than formerly, but other foundations had sprung into existence. So far as the new universities in great cities were concerned, it might be said that they were predominantly scientific, and they also devoted special attention to the needs of practical life, professional, industrial, and commercial—a state of affairs which was extending itself to the older universities, especially Cambridge. Dealing with higher education in South Africa, Sir Richard said: "If I am not mistaken, there is in South Africa a genuine and a keen desire for efficient education of the highest type. A sound liberal education is desired for all who can profit by it, whatever their future callings are to be. But the practical and immediate need for the organising of the highest teaching is felt, I believe, more particularly in regard to three great professions—the profession of engineering, in all its branches; the profession of agriculture (including forestry); and the profession of education itself, on which the intellectual future of South Africa must so largely and directly depend. Unstinted gratitude is due also to the University of the Cape of Good Hope. The primary needs of daily life in a new country make demands for certain forms of higher training—demands which may be unable to wait for the development of anything so complex and costly as a teaching university. It is necessary to provide a training for men who shall be able to supervise the building of houses, the making of roads, bridges, and railways, and to direct skilled labour in various useful arts and handicrafts. The first step in such a provision is to establish technical schools and institutes." Sir Richard paid a high tribute to the German technical foundations, and considered that, in the absence of similar institutions here, some of their functions might be included in the curriculum of the newer universities. He made some interesting observations on the part which science plays in the higher education, lending, as it does, a practical element to the more ornamental side of intellectual achievements, such as literature. In conclusion, he emphasised the need of well-organised secondary schools, so that pupils shall be prepared to fully benefit by university teaching.

Power Factor in Induction Motors.—In the *Electrical World* of New York Mr. A. A. Averrett has a contribution upon the question of whether, other features being equal, three-phase or two-phase induction motors have the higher power factor. The author advances arguments in favour of the former. Three-phase and two-phase motors are actually wound six-phase and four-phase (60deg. and 90deg. windings) respectively. The operating conditions for induction motors are somewhat similar to those

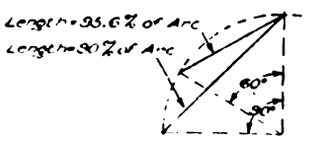

FIG. 1.

for six-phase and four-phase rotary converters, in which the six-phase winding gives better results than the four-phase winding. The reason for the superiority of the three-phase 60deg. winding lies in the fact that the ratio of effective turns to actual turns is as the chord to the arc. This ratio is $\frac{3}{\pi}$ in 60deg. windings, while in two-phase (90deg) windings the ratio is $\frac{2\sqrt{2}}{\pi}$. In other words, the 60deg. winding has 95·6 per cent. of the actual turns effective, while the 90deg. winding has only 90 per cent. of the turns effective. Fig. 1 graphically illustrates this advantage of the three-phase over the two-phase winding, by showing how the length of the chord approaches the length of the arc more nearly in the chord which subtends an angle of 60deg. than in the chord which subtends an angle of 90deg.

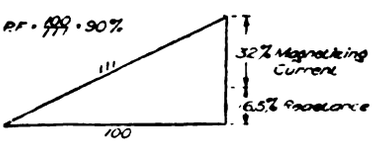

FIG. 2.—Method of Finding Power Factor.

A typical General Electric three-phase motor having a power factor of ·90 at full load and ·83 at half load will, the author states, have about ·32 magnetising current, ·165 reactance, and a stationary impedance current of about 5·75 times full-load current. The same motor if wound two-phase will have ·36 magnetising current and the same reactance (·165) at full load, which will give a power factor of ·89; while the half-load power factor will be ·80. Mr. Averrett concludes that two-phase motors have inherently a lower factor than three-phase motors, though it is possible to show as favourable a power factor for the two-phase as for the three-phase winding by the use of an excessive amount of material and at the expense of efficiency.

Telegraphy and Telephony at the Peace Conference.—With a view to coping with the needs of the Russian and Japanese peace envoys and supplying the Press with the latest news, extensive preparations were made for the handling of telegraph and telephone messages at Portsmouth, U.S.A., by the Western Union Telegraph Company, the Postal Telegraph-Cable Company, and the New England Telephone and Telegraph Company. The large amount of Press matter and the official communications anticipated between the envoys and their respective Governments called for unusual means of handling the

Digitized by Google

situation, and on Saturday, Aug. 5, two days before the arrival of the Russian and Japanese plenipotentiaries, the arrangements were practically finished. Both the Western Union and Postal Companies established auxiliary telegraph and cable offices at the Hotel Wentworth, Newcastle, where the envoys are staying. The Western Union office is equipped with four quadruplexes, three duplexes, and 11 single loops, besides special private loops in the Japanese and Russian suites, whence direct communication is maintained with the Atlantic cables at Newfoundland, *viâ* Canso, and also with the Western Union offices in New York. From this latter point the Japanese diplomatic matter was sent *viâ* land lines to San Francisco over a direct circuit. From San Francisco messages were transmitted *viâ* the Pacific cable through Honolulu, Midway, Guam, Manilla, and Hong Kong to Japan. Facilities for the work of 25 extra operators were available at the Hotel Wentworth, which is connected by direct wire with the Halifax-Rye Beach cable station at Rye Beach, N.H., as well as with the land lines of the Western Union Company. An extra office, largely for the use of newspaper correspondents, was set up opposite the main office. About 1,500 cells of gravity battery are installed in this building and 25 extra operators can be put at work if necessary, besides 15 operators in the main office. Two special circuits for the use of the envoys and their staffs were also installed between the Portsmouth Navy Yard and the main office. The Postal Telegraph Cable Company's arrangements correspond closely to those made by the Western Union. An auxiliary office at the Wentworth with four quadruplexes, three duplexes, ten single loops and private loops to the envoys' suites was installed, the hotel being connected with the main office on Congress-street, Portsmouth, by a 22-wire aerial cable about 3½ miles in length. All the Wentworth service is looped through this main office, which is connected by direct wires with the Postal and Commercial Cable offices in New York. Russian messages were expected to pass *viâ* the Commercial cables to San Francisco, and thence *viâ* the Pacific cable, which the company controls, to Hong Kong and Japan. The main office at Portsmouth contains the company's "portable quads," which are transported from place to place in order to meet emergency calls, and also three $\frac{1}{10}$-kw. portable dynamos mounted on boxes equipped with rollers. These dynamos are supplied with 125-volt direct current from the Rockingham County Light and Power Co.'s station in Portsmouth, and are designed for 115 volts primary and 380 volts secondary current. Fifty extra operators can be accommodated if necessary at the postal offices, and two navy yard circuits are also in place for postal service. The New England Telephone and Telegraph Co. has doubled its trunk line facilities between Portsmouth and Boston, making a total of eight circuits available. It has also placed in commission one special toll circuit between Portsmouth and Worcester, Mass., for New York and Washington traffic. Two additional recording operators are ready for business at the Portsmouth central offices, an additional station has been set up at the Hotel Wentworth, and three extra stations at the navy yard for the exclusive use of the conference. This is another notable instance of the utility of the telegraph and telephone, and nobody showed greater appreciation of it than the big dailies.

Alternating-Current Motors—A design of alternating-current motor of the commutator type intended to obviate sparking has been patented in this country by Mr. R. McNeill, of New York. The rotary armature, A, shown in the first diagram, which we reproduce from the *Official Patents Journal*, is provided with two or more independent circuits, which are connected to alternate bars, c_1 c or c_1' c', on the commutator, so that each is always connected to a pair of brushes, b b or b' b', but cannot be short-circuited by any of the brushes, thus obviating sparking. It will be seen in Fig. 1 that the circuits are arranged quite independently of each other, but this plan is not essential so long as the electrical independence of the circuits between brushes of the same polarity is observed. For instance, the method of interconnecting three circuits, as shown in Fig. 2, may be employed. Any number of brush

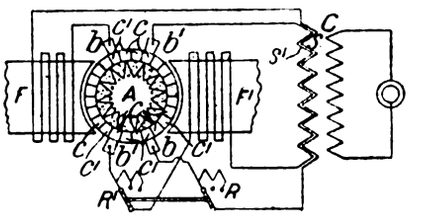

FIG 1.

circuits may be used. The armature windings may be in series with the field windings, F F', and are supplied with currents of the same phase, obtained for example, by means of two similar secondaries, s s (Fig. 1), on a transformer, C. Alternatively, the armature circuits may be energised independently of the fields, the field current counteracting the greater reactance of the field circuit, and thus producing

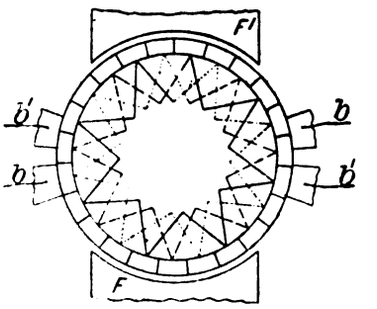

FIG. 2.

synchronism of the armature and field magnetisations. Any suitable arrangements may be used for producing similar currents in the armature circuits and a leading current in the field circuit. The two arrangements of separate field and armature circuits and series connected field and armature circuits may be combined in the one motor. This arrangement allows of the field and armature magnetisations being brought more nearly into phase than

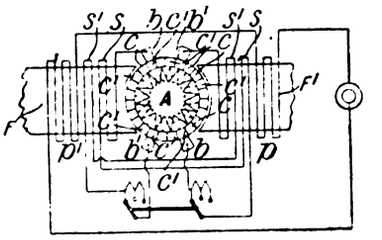

FIG. 3.

can be accomplished by other methods. A rheostat, R R' (Fig. 1), choke coils, or a switch connected to taps in the secondaries, s s', may be provided for starting or speed varying purposes. In Fig. 3 is seen a motor having the field wound with coils, p p' and s s', which act as transformer primaries and secondaries respectively. Parallel or series connections of similar coils on the two parts, F F', of the field magnet may be employed. Either the armature or the field magnet may operate as rotor.

THE ERITH ELECTRIC TRAMWAYS.

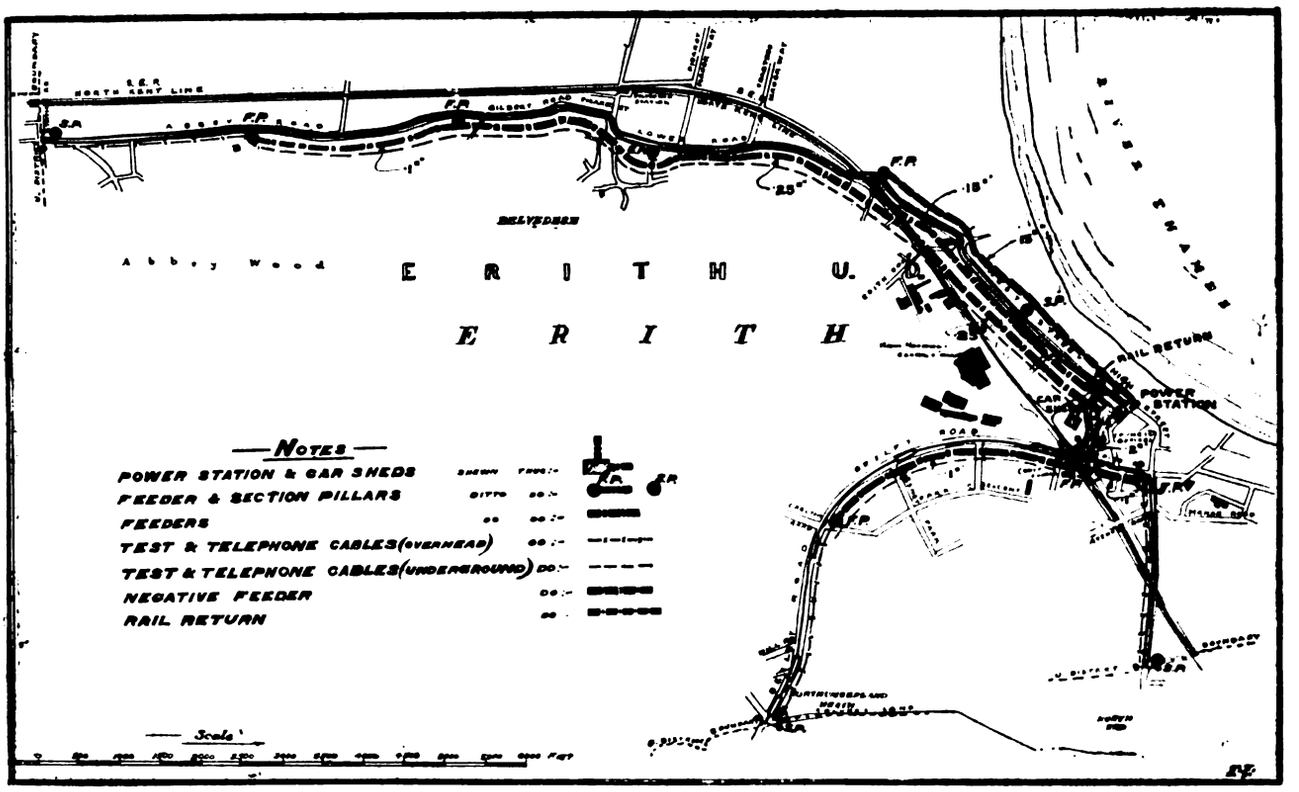

FIG. 1.—Route Map of the Erith Council's Tramways and of the Feeders supplying the same.

The sections of the tramways of the Erith Urban District Council which are to be opened on Saturday next will be of service for local traffic, but their full usefulness will not be realised until certain tramways in adjoining areas have been constructed. The original scheme for which parliamentary sanction was sought in 1903 was a complete one, and would have provided for a cheap means of communication with Woolwich and London. The routes now constructed are shown in the map given herewith, from which it will be seen that there are practically three lines radiating from the centre of Erith. The longest of these goes to Abbey Wood and ends at the boundary of the London County Council. In the scheme drawn up by Mr. W. C. C. Hawtayne, the consulting engineer to the Council, and included in the 1903 Bill, this line was continued to Wellinglane, where it joined the Bexley tramway to Woolwich. The extension in question was to pass along a new road made by the Woolwich Co-operative Society through their private property, but it lay within the Woolwich borough area and also within the county of London. Opposition was, therefore, brought against this Bill, and was so far successful that the London County Council are now bound to construct the line in question. Should they not do so within a predetermined time, the Erith Council may undertake the work. This link would complete the connection by tramway between Erith and London, but its great usefulness would be for traffic between Woolwich and Erith.

The present system is connected to the Bexley Council's line by a physical junction, and through running is to be arranged. The details as to the through service are not yet fixed between the two Councils, but as it will be of great value to both, no difficulty should arise. The junction between the systems is at Northumberland Heath. The third line goes to North End, near the Dartford district. It is possible that this may eventally be extended and linked up to the Dartford tramways now under construc tion, but it would involve the making of a new road for the purpose. The Erith tramways may for the time being be considered as an isolated system, which will have a considerable traffic due to the large number of workmen employed in the engineering works in the centre of the district, who will now be able to live farther from the factories. The through system to Bexley will be of special service in this respect.

In the Bill authorising the construction of the tramways powers to make street improvements were included, several

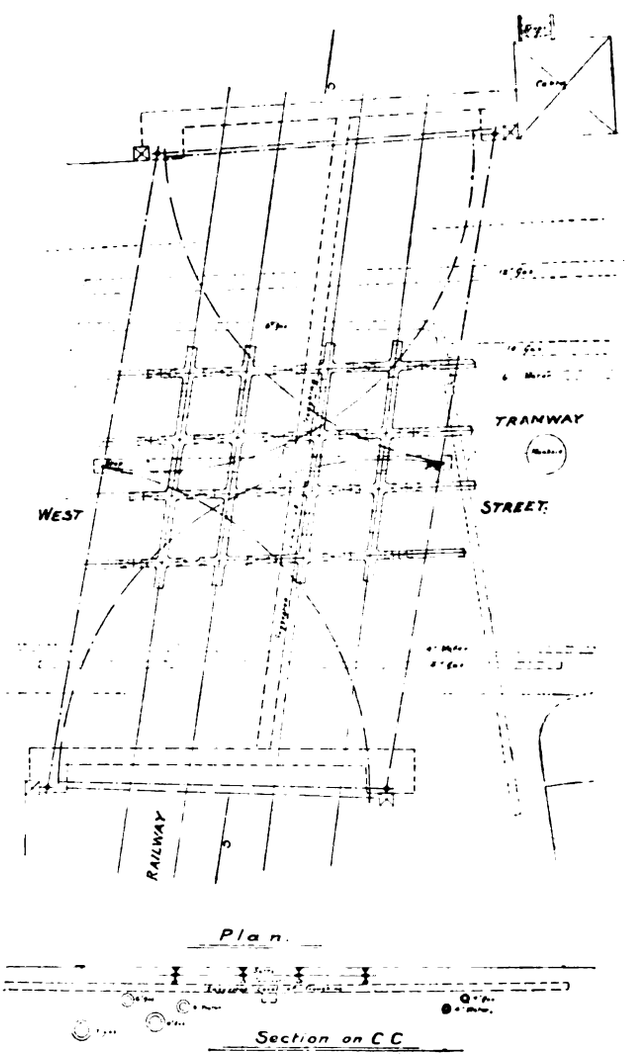

FIG. 2.—Plan of Special Work supplied by Messrs. Hadfields for crossing Siding to Parishes' Ballast Wharf. The Special Gates are also indicated.

of which are of great value apart from the electric car service. The most important of these is the bridge over

Digitized by Google

the South-Eastern Railway which replaces a level crossing. This work, too, has been carried out by Mr. Hawtayne.

which is developing into the main traffic route from Erith to London. The South-Eastern and Chatham Railway is

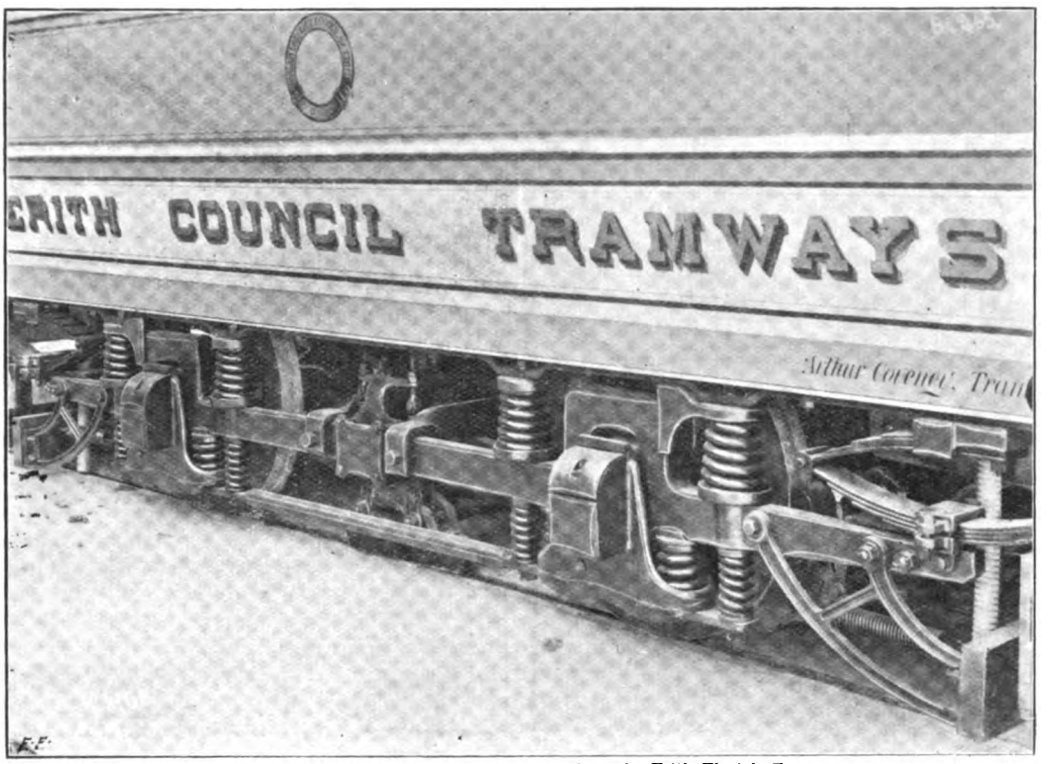

FIG. 3.—The Mountain and Gibson Truck used on the Erith Electric Tramcars.

The need for such a road diversion is emphasised by the fact that a boy was killed by a train on a level

throughout this section approximately a surface line, and the crossing is also at a very acute angle. To keep the

crossing in Erith the day after the official inspection of the tramways. This crossing occurs on the Lower-road,

approach gradients as flat as possible, it was essential that the depth of bridge deck should be kept very small. The

Digitized by Google

existing double line of railway is crossed by a span of 26ft. on the square and 40ft. on skew, two side spans, 14ft. 6in. on square and 22ft. 3in. on skew, being formed to allow of a future doubling of the railway. The bridge is designed to carry ordinary road traffic and a trolley car weighted up to 32 tons on a 12ft. by 6ft. wheel base. Trough flooring with parapet girders allowed of the shallowest deck construction, and was decided on, the troughing being Messrs. Dorman-Long's E max. in centre span and E min. in side spans. The

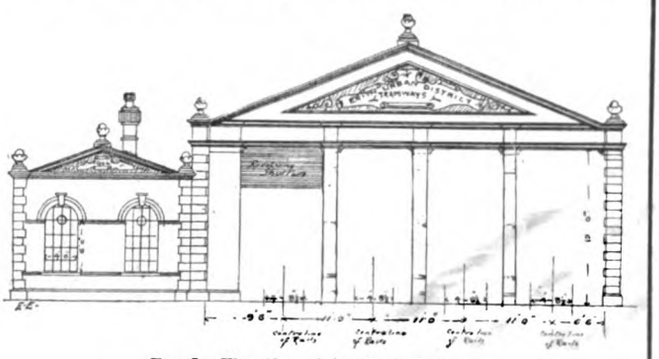

FIG. 5.—Elevation of Car Shed Entrance.

gradients of approaches were thus kept to 1 in 24·8 on the west side and 1 in 30 on the east. The bridge foundations were carried through clay and peat of the old marsh land to ballast at a depth of about 12ft., and as those for the intermediate piers were close to the running road of the South-Eastern and Chatham Railway careful timbering was necessary. These pier foundations, each 80ft. long, were carried out in 20ft. lengths, heavy baulks being placed under the rails adjacent to each length. The contract for this bridge was placed last summer in the hands of Messrs. W. Pattinson and Sons, Limited, of 50, Parliament-street, Westminster, who carried out the whole of the work without

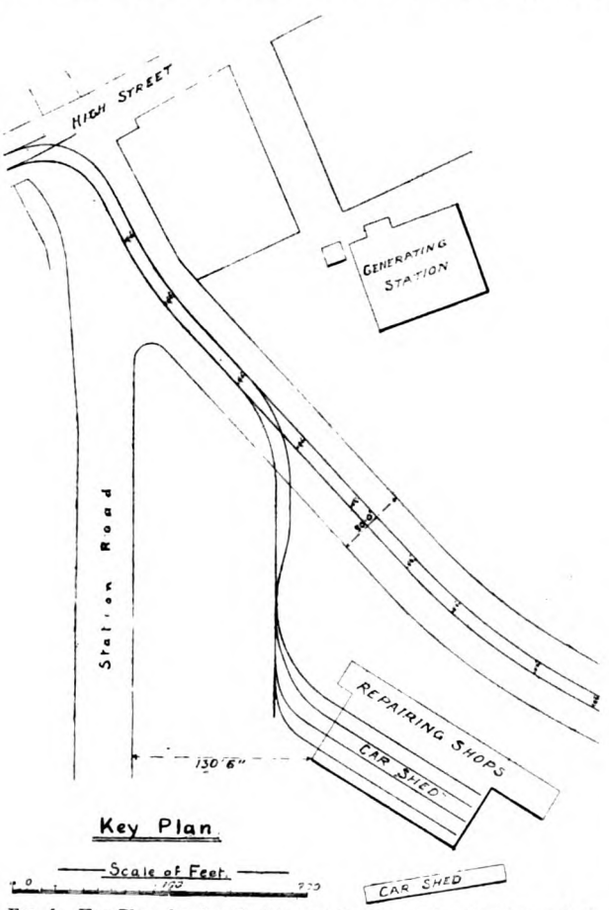

FIG. 6.—Key Plan showing Positions of the Generating Station and Car Sheds on the Council's Estate.

in any way interfering with the traffic on the South-Eastern and Chatham Railway. Mr. J. Pluck acted throughout as clerk of works.

The contracts for the supply of rails, etc., and the construction of all track work and the conduits were placed in the hands of Messrs. R. W. Blackwell and Co., Limited, Messrs. Bolckow, Vaughan, and Co., Limited, being sub-contractors for the supply of rails and fastenings, Messrs. Hadfield being the sub-contractors for all points, crossings, and special work. The Associated Cement Company, Limited, supplied all the cement used. The lines at present constructed have a route mileage of about 4·7, and an equivalent single-track mileage of 8·4 miles, the whole of the main line from Abbey Wood to Erith being double track. Connection is made with the Bexley tramway system at Northumberland Heath. The rail joints are fished and anchored with Cooper and Howard Smith's anchor joints, intermediate anchors being also used in the middle of the rails, which are No. 3 B.S. 100lb. per yard and 60ft. in length. The centres of the tracks are laid 8ft. 6in. apart except on curves, where this distance is increased to allow of the increased overcharge of the cars. Though only 6ft. wheel-base truck cars 28ft. long are at present in use, the track has been laid down to give the clearance required for the large London County Council bogie type of car. The rails are laid on a bed of 6 to 1 Portland

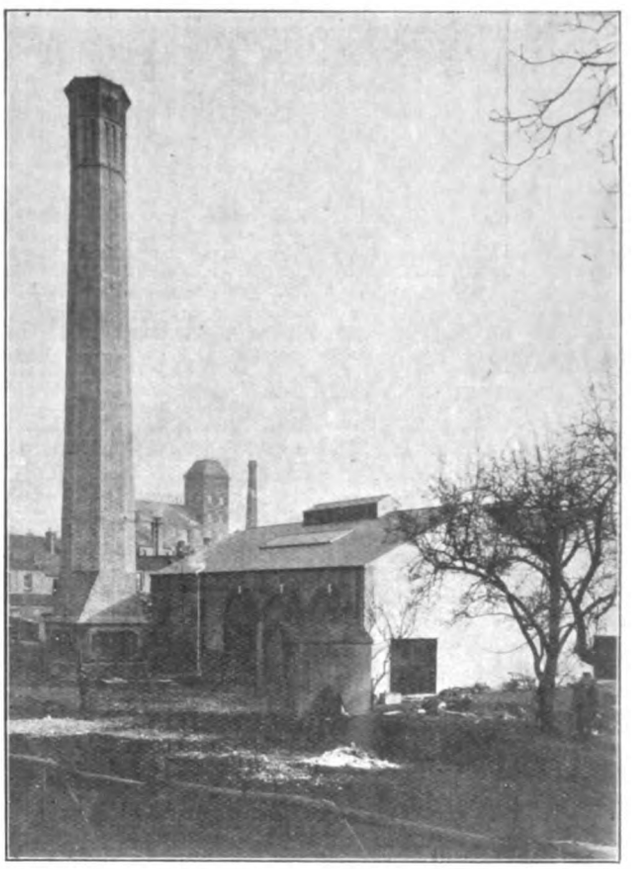

FIG. 7.—View of the Erith Electricity Works.

cement concrete, having a minimum thickness of 6in. As the road from Abbey Wood to Erith follows for the most part the old track running along the edge of the marshes, the bottom is often very soft, and where necessary the thickness of concrete has been considerably increased. The paving setts are 5in. Norwegian granite in the majority of the route, but through Erith proper and to Belvedere Guernsey granite is employed. Black butt and jarrah wood is used in front of places of worship, schools, etc. The joints of the paving were racked and run with pitch for half their depth, and grouted with Portland cement and sand for the remainder, but where paving was carried out in frosty weather to prevent delay, pitch was used for the whole depth. The standard points used in passing places are straight run in, with a 200ft. radius run out, which give very easy running, and it is expected that the saving in wear and tear on the cars and track will amply repay the increased cost of these points, which are of manganese steel and 15ft. long. On sharp curves the groove of rail is increased from $1\frac{1}{8}$in. to $1\frac{1}{4}$in., and the B.S. No. 3 C rail 106lb. per yard is employed. Double bonding of 4/0 crown bonds is used at the rail joints, and

Digitized by Google

long bonds are carried past all points and crossings. Cross bonds in track and inter-track bonds every 40 yards. Conduits, with three or four ways, are laid under the track to allow of the cable system being drawn in, and draw boxes of ample size are constructed about 100 yards apart, or at such shorter distances as will allow of straight runs for the conduits between the boxes. The steepest grade on the systems is 1 in 20 and the sharpest curve 40ft. radius. In West-street there are two level crossings, at Messrs. Parishes' ballast wharf and at Messrs. Cory's wharf respectively. The crossings (Fig. 2) are of manganese steel with the usual groove for tramrail and a groove 2in. wide and 1¾in. deep for siding rail, this groove being contracted at the point of crossing to 1⅝in. wide and 1½in. deep to reduce the bump to trucks and cars passing over. The clerk of works for the track construction and overhead work was Mr. J. W. B. Carruthers.

and lightning arresters, were supplied by the Callender's Cable Company, and are of their standard type.

The present rolling-stock consists of 14 double-deck cars, carried on four-wheeled trucks as illustrated in Fig. 3. These cars and their equipments were supplied by the British Westinghouse Company, the bodies being made by the Brush Company and the trucks by Messrs. Mountain and Gibson. The wheels and axles were made by Baker and Co., and the whole of the electrical equipment by the Westinghouse Company. The cars are 28ft. long over fenders by 7ft. over-all width. The brakes on the cars consist of the ordinary hand ratchet type and the British Westinghouse magnetic track brake. Messrs. Mountain and Gibson were responsible for the trigger type of life-guards used on the cars, and also for the trolleys which have the wood trolley heads. Seven of the cars have top deck covers. The direction indicators are of the revolving

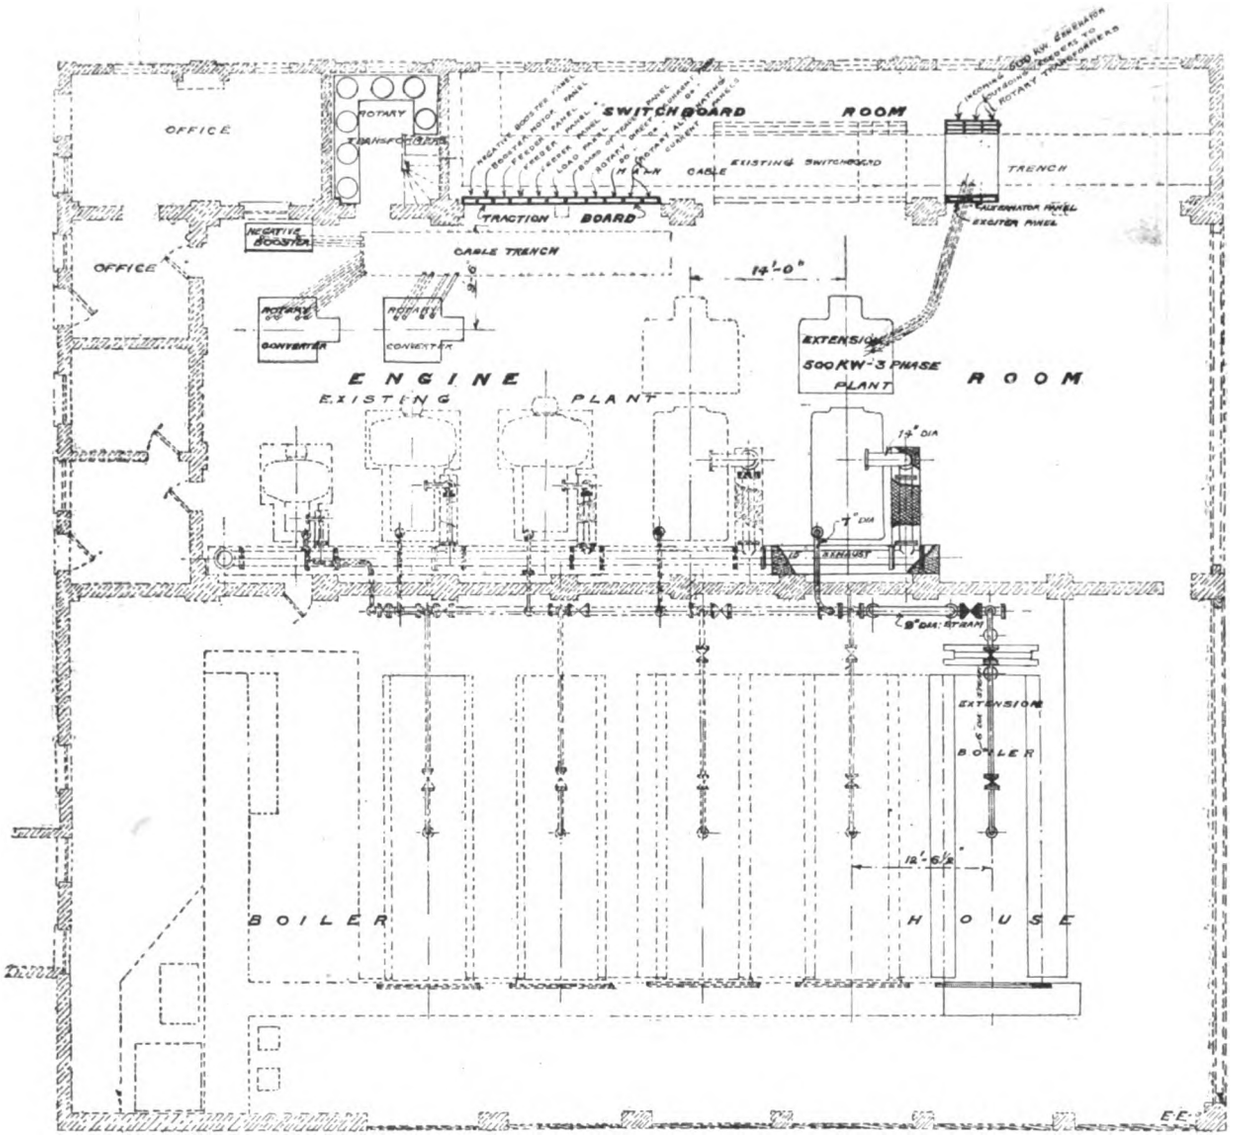

FIG. 8.—Plan of the Erith Electricity Works with the Latest Extensions shown in full lines.

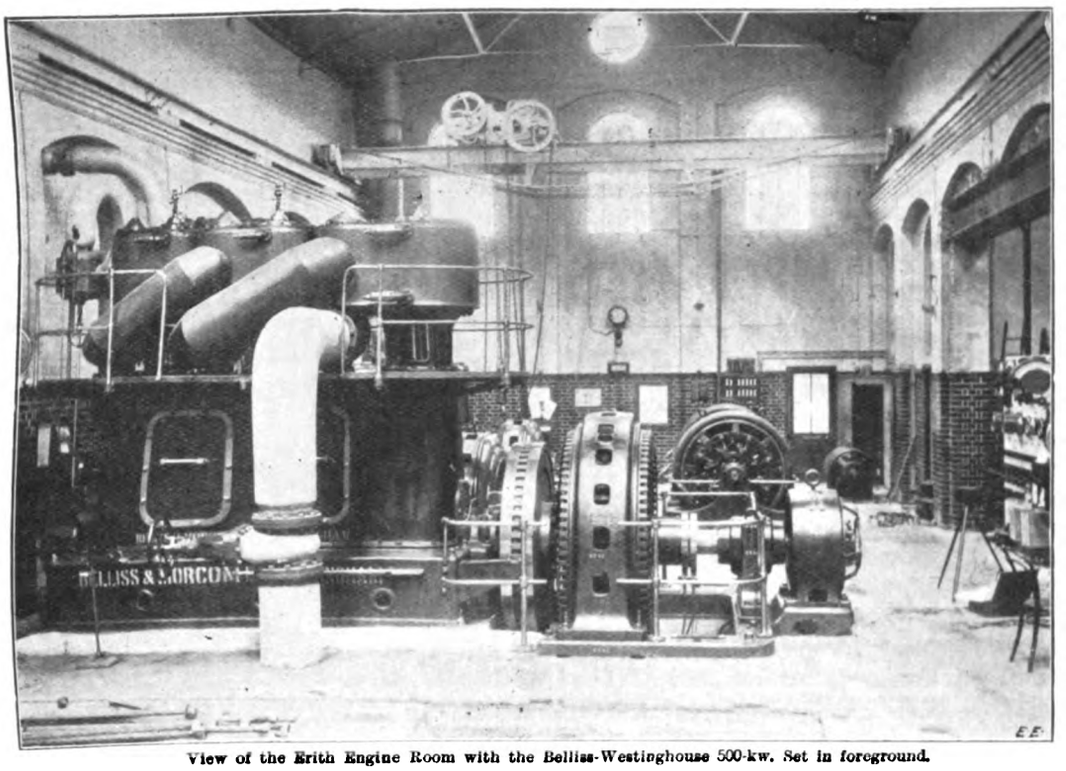
The overhead equipment was provided by the Brush Electrical Engineering Company. The bracket-arm construction with side poles is used throughout except at curves and junctions, where span construction is adopted. The bracket arms vary in four sizes between 10ft. 6in. to 16ft. 6in. in length. The poles are 31ft. long, of which 25ft. is above ground. These poles were supplied by Messrs. Stewart and Lloyds through the Brush Company, and are of three sizes as follows: light poles, 731lb. in weight; medium poles, 923lb. in weight; and heavy poles, 1,206lb. in weight. The flexible system of suspension is adopted throughout with trolley wire of copper 3/0 S.W.G. The guard wires are of stranded galvanised steel. The poles are earthed at every fifth standard, where guard wires are used. The cars are of the Phillips type, and sectional insulators are placed at half-mile intervals. The section pillars, fitted with the necessary controlling switches, telephone plugs, blind type, with incandescent lamps for illuminating them at night. The lighting of the cars is done by 17 100-volt lamps of 16 c.p. per car, arranged on three circuits. The stairways to the upper decks are of the reversed type. The Council have also purchased a track sweeper and watering car manufactured by Messrs. Mountain and Gibson, and equipped by the British Westinginghouse Company with the necessary electrical gear.

The car-sheds (Figs. 4 and 5) are situated on the Council's Walnut Tree Estate, on which the various municipal undertakings are accommodated. Fig. 6 shows a block plan of the same. The power-house is divided from the car-sheds by the new road made through the estate. The sheds have four tracks, and can accommodate 16 cars. The tracks are carried on pillars, so that there is a clear basement under the shed, which greatly facilitates inspection and repairs. Offices for the tramway manager and his staff are pro-

Digitized by Google

vided, and a messroom for the men. Repair shops complete the accommodation on the ground floor. In the basement various stores have been arranged, as shown in the plan.

and Construction Company, who first supported the undertaking by laying down motors of 120 h.p. This firm has since increased to a considerable extent the number of three-phase motors in use, and has avoided in this way the



View of the Erith Engine Room with the Belliss-Westinghouse 500-kw. Set in foreground.

The power station at Erith, Fig. 7, was the first to be laid down in this country for the distribution of electrical energy on the three-phase system by a local authority. We described it fully in our issue of June 23, 1903. The adoption of this system by Mr. W. C. C. Hawtayne, the consulting electrical engineer, has been amply justified by the power load which has been obtained from the manufacturing laying down of more boilers and generating plant. Their consumption now has passed 250,000 units per annum, and the bulk of this is consumed during the day, when the lighting load is small. Messrs. Vickers, Sons, and Maxim now take 100 h.p. from this system under a five years' agreement, and the Co-operative Society have installed motors with an aggregate of over 60 h.p.

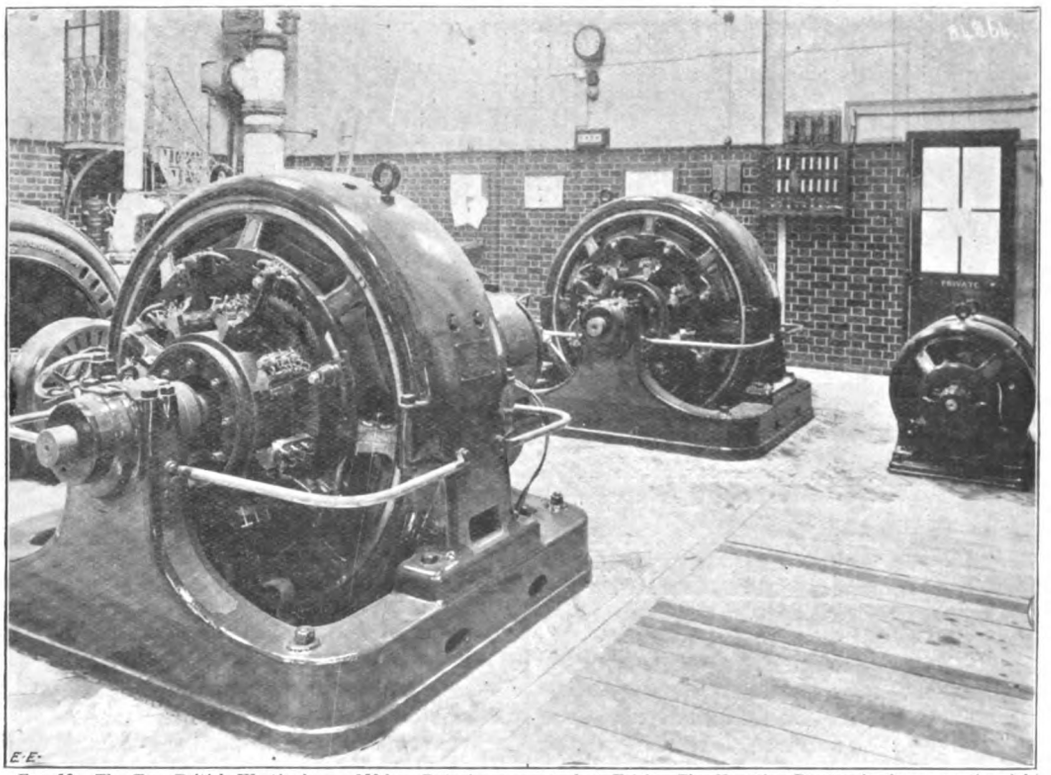


Fig. 10.—The Two British Westinghouse 150-kw. Rotaries as erected at Erith. The Negative Booster is shown on the right.

works situated within the Erith district. Many of these works have found it more economical to take their supply from the Urban District Council's station than to put down or extend their own electrical systems of distribution. Amongst the largest consumers is the Callender's Cable

The tramway load now to be supplied has necessitated the laying down of more plant, as can be seen from Fig. 8, but the generating plant is still of the three-phase type, and the lighting, power, and traction loads will all be supplied from the same high-tension switchboard. Two

Digitized by Google

rotary converters are used to change the three-phase currents into direct current. These are placed within the generating station, but the complete scheme involves the use of another rotary in a transforming station in Upper Belvedere. This station has been constructed as a kiosk, and is at present used for lighting work only, but the space for the rotary converter is reserved.

Including the new plant, the generating works now contain five Lancashire boilers, two of which are 28ft. by 8ft., by Spurr, Inman, and Co., rated at 6,000lb. per hour each and hand-fired. The remaining three, also 28ft. by 8ft. 6in., are by Yates and Thom, rated at 7,500lb. per hour each, and fitted with Bennis compressed-air stokers and Sugden's superheaters capable of superheating the steam to 100deg. F. above normal temperature. The boilers are fitted with main and auxiliary steam-valves, spring-loaded and dead-weight safety-valves of ample areas, duplicate feed valves, and injectors capable of maintaining full feed supply. The boilers are fed by two steam-pumps of Hall's compound make of 1,500 and 1,800 gallons per hour respectively, one motor-driven triple-ram pump of Pearn's make and 1,500 gallons per hour, and one tail end pump on the condenser of 1,500 gallons per hour capacity—all of which deliver through Rankin's pressure filters, there being two of these installed. The boilers are covered with Haacke's composition, and set with Poulton's curvilinear blocks and covers.

Steam Alternators.—There is one of 50 kw. and two of 150 kw. each of the International Electric Engineering Company's make, driven by Allen compound engines, and two of 500 kw. each of British Westinghouse make, driven by Belliss triple-expansion engines; all are capable of giving 20 per cent. overload for one hour. The exciters are direct driven on a continuation of the rotor shaft. The alternators are arranged with revolving fields. Fig. 9 shows the engine-room with the new plant in the foreground.

The two rotary converters (Fig. 10) are of 150 kw. capacity each. They have been placed at the end of the station occupied by the smaller steam alternators. Room has also been found there for the negative booster, which is also of the Westinghouse type, and is capable of dealing with 7·5 kw. As regards the switchboard, the high-tension gear is arranged with front and back panels separated by a 3ft. gangway. All high-tension apparatus is contained on the back framework and panels on cubicle system, the switch handles and all measuring instruments are placed on the front panels. All the panels are of white marble. The original board, made by the International Engineering Company, was extended by the General Electric Company, and further extended and partly rearranged by Messrs. Kelvin and James White. The low-tension board contains tramway feeders and Board of Trade panels, rotary converter, and negative booster panels. From this switchboard the cables, indicated in Fig. 1, are led to the tramway system. This work has been done by the Callender Cable and Construction Company. The cables are of the vulcanised bitumen type drawn into conduits laid under the track. The total length of these feeders is 2½ miles, and their section varies from ·1 up to ·25 square inch. The testing and telephone cables are carried overhead on the last half-mile section of each route.

Such is the equipment of the Erith tramways, which are to be formally opened on Saturday under the management of Mr. A. Coveney. Mr. P. W. Masson, as chairman of the Tramway Committee, has had a great deal to do with the carrying through of the scheme, and we are sure that neither the Council nor their consulting engineer, Mr. W. C. C. Hawtayne, will be content until the system is linked up to the London County Council tramways south of the Thames.

FOCHABERS ELECTRIC LIGHTING.

An interesting water-power plant for the electric lighting of Gordon Castle, the Scottish seat of the Duke of Richmond and Gordon, and also of the village of Fochabers, is nearly completed. The engineers carrying out the work are Messrs. Drake and Gorham, Limited. The interest in the scheme lies in the fact that the water of the Spey is to be used to provide the necessary energy. The works in question are situated on the banks of the Spey, about half a mile above the bridge at Fochabers. Ample water power is available, but, in common with other water plants in the United Kingdom, the normal fall of 14ft. decreases considerably in time of flood. In consequence of this the plant has needed to be designed on ample lines, so that the turbines can give their full output when the water in the tail race rises 6ft. or 7ft. Horizontal turbines, supplied by Messrs Carrick and Ritchie, of Edinburgh, are used. The open lade from the intake to the power-house is some 1,300 yards long, and has been constructed in concrete. The soil through which the lade had to be dug was nearly all loose gravel, which necessitated the lining of the sides and bottom with concrete. The width of the lade is 15ft. and the depth of water in it will be 3ft. The intake is at a natural pool in the river, and the quantity of water taken from the stream is such a small proportion of the total volume that there was no need to construct a dam in the river bed. The lade terminates in a large wooden tank, from the bottom of which the turbines are supplied by means of cast-iron pipes.

The turbine-house proper is built with concrete, and is provided with watertight doors so that the shafts can be withdrawn at any time. Of the two turbines now installed the larger will pass some 3,880 cubic feet of water per minute and the smaller one 2,300 cubic feet. Their horse-powers working on a 10ft. head are respectively 50 h.p. and 30 h.p. Their diameters are 27in. and 21in. respectively. Both these turbines drive dynamos by means of belts, the dynamos being placed at a much higher level, so that they are well above the highest flood ever recorded.

Two dynamos are provided, each with a series as well as a shunt winding, a plug being provided for cutting out the series winding when the machines are used for charging the accumulator. In order to prevent mistakes, the switch-board has been so arranged that the machines cannot be switched on to the accumulator unless the series winding has been first cut out.

The distribution is on the three-wire system, with 400 volts between the outer conductors. The accumulator will be used only for the castle, the village lighting being run direct from the dynamos, the turbines being fitted with electric governors and the dynamos slightly over-compounded to make up for the loss in the feeders. A compound-wound balancer is also provided, and to this is coupled the booster for charging the battery. The battery consists of 214 hanging-type cells in glass boxes of 360 ampere-hours capacity.

The distribution is effected by means of paper-insulated cables, lead-covered and armoured, laid direct in the ground. The wiring in the houses in the village is being carried out by means of vulcanised rubber wire run on insulators. Originally it was intended to light the castle only, but the inhabitants of Fochabers petitioned the Duke to light the village as well.

Mr. Delmar Morgan has been responsible to Messrs. Drake and Gorham for the supervision of this work, as it comes within the Glasgow district, of which he has charge. The same firm have just completed the lighting of Goodwood House, the Duke of Richmond's southern home. In this case, water not being available, suction producers and gas-engines have been used.

THE WITWATERSRAND DEEP ELECTRICAL PLANT.

There is little doubt but that mines offer a grand field for electrical power. This is especially the case in regard to the big groups of mines on the Rand and in South Africa generally, where the conditions favour the adoption of up-to-date methods and render conservatism impossible. Now that electric driving of stamp batteries has entered the range of practical politics, we may possibly be on the eve of great developments in this direction. It is, however, unwise to be prophetic in these days. The scope of this article is rather to describe one of the many electrical plants which have been actually installed—to be precise, the plant on the property of the Witwatersrand Deep Gold

Digitized by Google

Mining Company, Limited. The construction for the mills (200 stamps) has only recently been completed, and the same may be said of the electrical installation, which is, therefore, of the most modern type. It may be explained here for the information of those unacquainted with the district or conditions under which the various properties are managed and worked, that the mines on the Witwatersrand stretch almost in a line 30 miles east and west of Johannesburg. It would be more correct, perhaps, to say a double line, as the deeps are all some few hundred yards south of the outcrop mines. All the mines are owned and worked by some seven or eight companies, each having a head office in Johannesburg, where are to be found the directors and mining consulting engineer, mechanical consulting engineer, electrical consulting engineer, and the secretary for the group. One mining house may own some 20 or 30 mines, and on each property or mine there is a general manager, secretary, underground foreman or mine captain, mechanical engineer, electrical engineer, compound manager, surface foreman, etc. On one or two mines the mechanical and electrical engineer are combined in one person. On others there are very small electrical plants, and the mechanical engineer has a foreman electrician under him. On a few mines the electrical engineer is both consulting and resident engineer. On others, again, the mechanical and electrical engineers are independent of one another, each looking after his own particular department. At present electricity is used chiefly for lighting, underground pumping, and driving workshop machinery, but it is fast finding a much more extended application, and in the opinion of those best able to judge the near future will see the large majority, if not all, of the mines equipped with electrical machinery not only for the purposes just enumerated, but also for driving stamp batteries, etc.

Reverting to the Witwatersrand Deep electrical installation, the main generating plant consists of two tandem compound horizontal engines by Douglas and Grant, of Kilcardie, each direct coupled to a 250-kw., three-phase, 50-cycle, 1,100-volt alternator of the Brush Electrical Engineering Company's revolving-field type, and one 430-kw., 1,100-volt, 50-cycle three-phase Curtis steam turbo-dynamo set by the American General Electric Company. All of these sets work condensing, the condensing plant for the first-mentioned being placed behind the engines. A feature of these horizontal engines, one of which is shown in Fig. 1, is the heavy flywheel with which each is provided. This, it will be seen, is mounted centrally between the engine and alternator. The position of the duplicate unit is to the right of the set shown in Fig. 1 at the south end of the engine-room. Although of nearly double the output, the relative compactness of the turbo set (Fig. 2) will be at once appreciated. The diameter of the turbine at the base is 8ft., and it stands 12ft. high in the north-west corner of the engine-room. Its rated output is obtained at a speed of 1,500 r.p.m., and with a steam pressure of 140lb. The Wheeler condenser which serves this set is placed in the pit shown in the foreground of Fig. 2. It has 2,800 square feet of cooling surface, and works in conjunction with a 10in. by 10in. Edwards air-pump. The theoretically possible vacuum obtainable with this condenser is equal to 24·5in. of mercury, while the

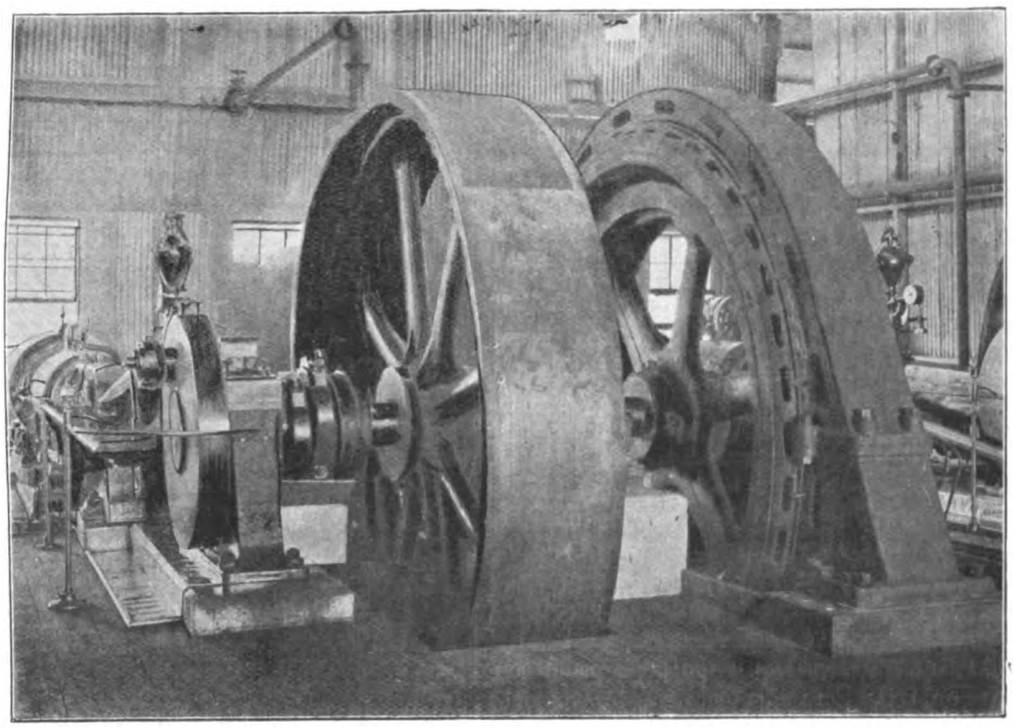

FIG. 1.—250-kw. Steam Alternator, South End of Engine Room, Witwatersrand Deep.

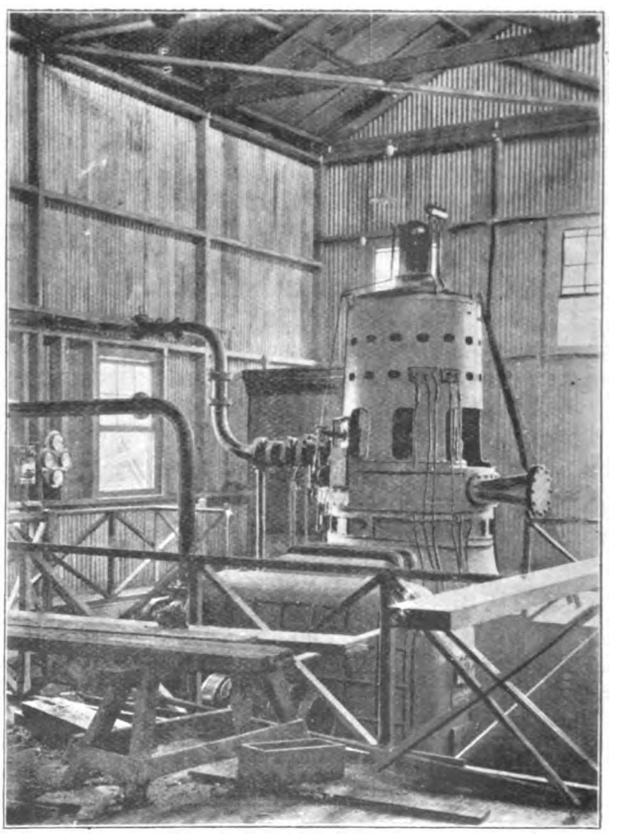

FIG. 2.—430-kw. Curtis Steam Turbo Set, North-West Corner of Engine Room, Witwatersrand Deep.

Digitized by Google

equivalent of 24in. was actually obtained on full load and 22½in. on three-quarter load during tests.

Excitation for the main generators is furnished by a four-pole dynamo (Fig. 3) yielding current at 100 to 130 volts pressure, and direct driven by a three-phase 47-h.p. motor. A 12-h.p. steam exciter serves to supply the initial excitation, after which the motor-generator set is switched in. The north-east corner of the engine-room (Fig. 3) further contains a 100-kw., three-phase, 30-cycle induction motor-generator, used as a synchronous motor for improving the bad power factor caused by the large number of small induction motors installed and many of the large ones being underloaded; a 200-kw. three-phase transformer, which supplies a transmission line to the Knight Central gold mine, 2½ miles distant; a 50-kw., three-phase, 1,100-to-110-volt transformer for lighting; a 30-kw., three-phase, 1,100-to-130-volt transformer for a like purpose; and a 1-kw. motor-generator used to charge accumulators for mine signals. A portion of the main switchboard and the separate switchboard for controlling the 40-kw. motor-driven exciter also appear in the illustration. The 200-kw. transformer serving the Knight Central transmission line is of the step-up and step-down type, being wound for transforming from 1,100 to 2,200 or 4,400 volts, and *vice versa*.

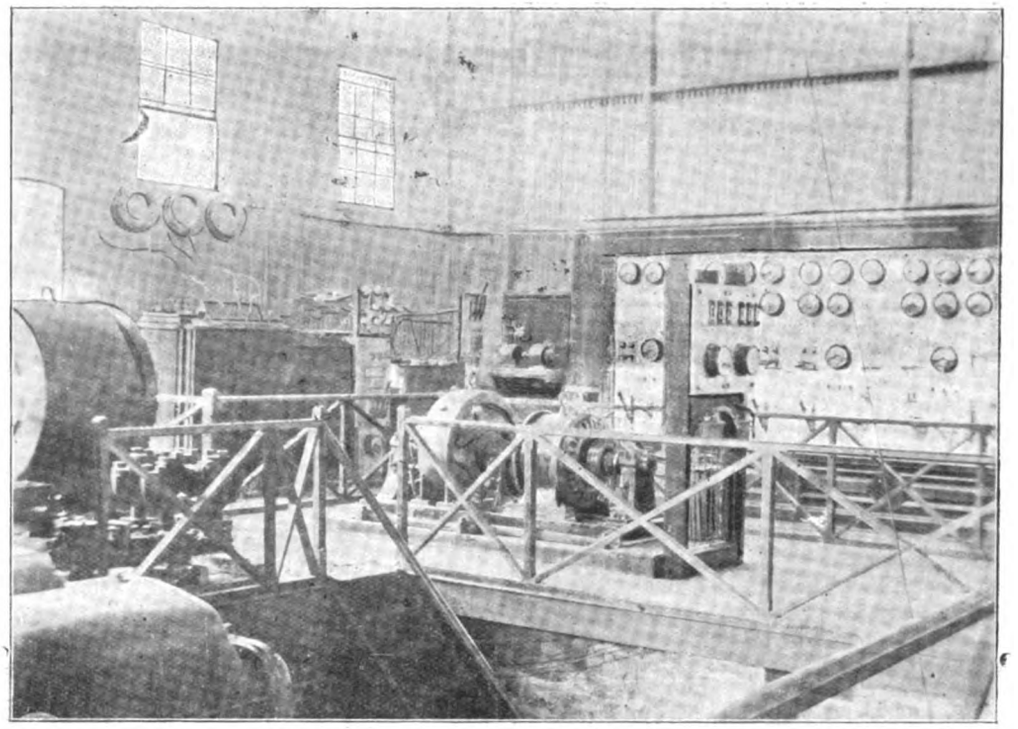

FIG. 3.—North-East Corner of Engine Room, Witwatersrand Deep.

At Knight Central there is installed a 150-h.p., three-phase, 50-cycle motor wound for 1,100 volts, driving by flexible coupling a 100-kw., 30-cycle, three-phase, 950-volt induction type generator, the speed being 400 r.p.m. to 500 r.p.m. The power is used chiefly for mine dralnage, one 25-h.p. motor being also employed in the workshops.

But to return to Witwatersrand Deep, it should be mentioned that the main switchboard (Figs. 3 and 4) is of white Italian marble mounted in a frame of polished teak, and consists of four generator panels, six circuit panels, and a voltage regulator panel. It remains to enumerate the different uses to which electric power is put on this property. For mine drainage there are installed in the

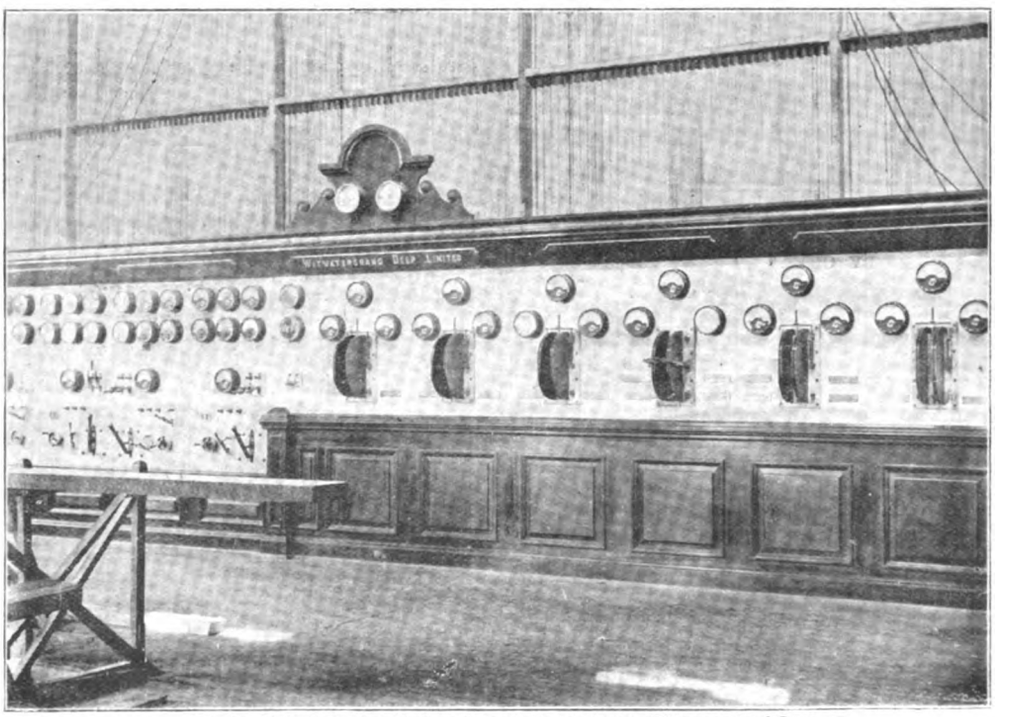

FIG. 4.—Main Switchboard, East Side of Engine Room, Witwatersrand Deep.

Digitized by Google

west shaft three 4½in. by 8in. three-throw pumps, connected by Hans Renolds chain gear to a corresponding number of 25-h.p., three-phase, 50-cycle, 120-volt motors, lifting from 1,520ft. to 1,050ft., and two 16in. by 16in. three-throw pumps geared to two 75-h.p, three-phase, 50-cycle, 110-volt motors for lifting from the 1,050ft. station to the surface level; in the east shaft a 6½in. by 8in. pump connected by Hans Renolds chain gear to a 35-h.p., three-phase, 50-cycle, 120-volt motor, and a 4½in. by 8in. pump driven in the same manner, both lifting to the surface a matter of some 420ft. Transformers wound for 1,100 to 110 volts are used in all the underground stations. Current also for mine lighting is taken from the mine pump-station transformers. The carpenters' shop equipment includes a 40-h.p., 50-cycle, three-phase motor wound for 1,100 volts, and used for driving a circular saw, and those of the fitters' and blacksmiths' shops a 20-h.p. motor and two 6½-h.p. motors respectively, the latter driving drill sharpeners, while the boilermakers' shop disposes of a 20-h.p. motor. In the boiler-house itself two 6½-h.p. motors are used to drive the scrapers of the Green's economisers installed; a 11-h.p. motor works the ash conveyor, and another of 6½ h.p. drives the feed pumps. The mill engine condensing plant is served by two motors of 20 h.p. each, and the condensing plant described in the foregoing by two of 20 h.p. and two of 6½ h.p. each. The ore crushing and sorting plant, including belt conveyors to the mill, accounts for five motors of 40 h.p. each, two of 20 h.p. each, and one of 5 h.p. The sands conveyor requires a motor of 40 h.p. to work it, and in the extractor house there are two 40-h.p., three 20-h.p., and three 11-h.p. motors, the list being completed by two machines employed in the assaying and sampling departments of 11 h.p. and 6½ h.p. respectively. Thus between 40 and 50 motors of various sizes are comprised in the equipment of this mine, while about 1,000 lamps are installed, the lighting supply being at a pressure of 120 volts and the power supply at 1,100 volts. The above list of motors may not make interesting reading, but it will serve to indicate some of the requirements of a Rand mine.

The chief electrical engineer on the Witwatersrand Deep property is Mr. Louis B. Wilmot, to whom we are indebted for the particulars here given, as also for the photographs from which our illustrations are reproduced. Mr. Wilmot recently spent some weeks in this country and is now in America, where it is his intention to remain for a short time before returning to South Africa. We trust, during his stay here, English firms were able to convince him of the superiority of their manufactures—certainly a desideratum in view of the important market which South Africa promises to become for electrical machinery and apparatus of all kinds.

NOTES ON AERIAL POWER LINES.—III.

BY CHE.

(Continued from page 227.)

In response to a request to give complete information *re* the electrical characteristics of power lines, it is proposed in this article to consider the two-phase system of transmission; it will add interest to the problem if we take the same data as were considered in the example of the three-phase system dealt with last week. Thus, let it be required to determine the size of wire and the drop in volts in the line for a two-phase system transmitting 1,000 h.p. a distance of 50 miles, given that the pressure at the receiving end is 20,000 volts, that the frequency of the supply current is 50 periods per second, and the permissible loss in the line 15 per cent. of the power delivered.

There are two cases to be considered, according as (α) the transmission is effected by means of four conductors, or (β) the transmission is effected by means of three conductors, one of which is $\sqrt{2}$ times the cross-sectional area of the phase wire and forms a common return wire to the two phases. To make the example more complete it will be well to consider two examples of each type—*i.e.*, (1) when the load is non-inductive or the power factor of the load is unity, and (2) when the power factor of the load is 0·8.

First Case. Power Factor Unity, System (α).—The proper disposition of the wires in the four-wire system is shown in Fig. 4, in which case the mutual induction between the wires will be zero, since they are symmetrically arranged at the corners of a square. It is clear that each phase

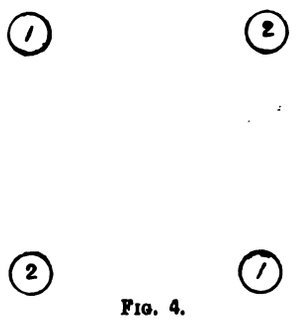

Fig. 4.

will transmit half the power, consequently the current per phase will be

$$I_1 = \frac{500 \times 746}{20{,}000} = 18{\cdot}65 \text{ amperes.}$$

If R_1 = resistance of 100 miles of wire, d_1 inch in diameter, forming one phase, we have

$$I_1^2 R_1 = \frac{15}{100} \times 500 \times 746 \text{ watts.}$$

But
$$R_1 = \frac{{\cdot}66}{10^6} \times \frac{100 \times 5{,}280 \times 12}{{\cdot}7854\, d_1^2}$$

$$\therefore d_1 = \sqrt{(18{\cdot}65)^2 \times \frac{{\cdot}66}{10^6} \times \frac{100 \times 5{,}280 \times 12}{{\cdot}7854 \times 75 \times 746}}$$

$$= 0{\cdot}1819 \text{in.}$$

which is approximately a No. 5 (B. & S.) wire. The area of this wire is approximately $A_1 = 0{\cdot}026$ square inch, and the resistance per phase

$$R_1 = \frac{{\cdot}66}{10^6} \times \frac{100 \times 5{,}280 \times 12}{0{\cdot}026}$$

$$= 160{\cdot}837 \text{ ohms.}$$

$\therefore$ resistance drop $R_1 I_1 = 160{\cdot}837 \times 18{\cdot}65 = 2{,}999{\cdot}6$ volts.

Since the pressure is high, it will be advisable to place the wires 54·6in. apart, in which case the reactance per phase will be $x_1 = 2\pi \sim L_1$, L_1 being the coefficient of self-induction per phase. By application of Maxwell's formula,

$$L_1 = 528 \left[15{\cdot}24 + 140{\cdot}366 \log \frac{54{\cdot}6}{{\cdot}091} \right] \times 10^{-6}$$

But
$$\log \frac{54{\cdot}6}{{\cdot}091} = 2{\cdot}778$$

$$\therefore L_1 = 0{\cdot}214 \text{ henry,}$$

and
$$x_1 = 2 \times 3{\cdot}1416 \times 50 \times {\cdot}214$$

$$= 67{\cdot}23 \text{ ohms,}$$

and the reactance drop $= 67{\cdot}23 \times 18{\cdot}65$

$$= 1{,}253{\cdot}8395 \text{ volts.}$$

The vector diagram for this case is given in Fig. 5, from which the generator pressure is found to be 23,033 volts;

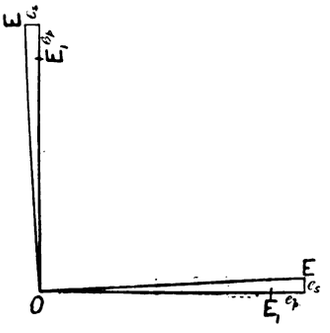

Fig. 5.

consequently the loss in volts in the line is 23,033 – 20,000 = 3,033 volts.

First Case. Unit Power Factor (β).—With three wires and a common return the current in each phase wire will

Digitized by Google

be the same as before, but with the same percentage line loss the size of wire will be different. Thus

$$I_2 = 18{\cdot}65 \text{ amperes},$$

and the line loss

$$2\,I_2^2\,R_2 + (\sqrt{2}\,I_2)^2\,\frac{R_2}{\sqrt{2}} = \frac{15}{100} \times 1{,}000 \times 746,$$

in which R_2 is the resistance of each phase wire 50 miles in length, and $\frac{R_2}{\sqrt{2}}$ is the resistance of the common return (50 miles long), since it is $\sqrt{2}$ times the area of each phase wire.

But

$$R_2 = \frac{\cdot 66}{10^6} \times \frac{50 \times 5{,}280 \times 12}{\cdot 7854\,d_2^2},$$

where d_2 is the diameter of each phase wire,

whence

$$d_2 = 0{\cdot}168\text{in.},$$

which is slightly larger than a No. 6 wire. Taking a No. 6 wire of diameter 0·162in. and area 0 0206 square inch, the resistance of 50 miles of which is 101·5 ohms, the area of the common return wire should, therefore, be $\sqrt{2} \times 0{\cdot}0206$, or 0·029128 square inch, corresponding to a diameter of 0·192in., which is slightly less than a No. 4 wire. It will, therefore, be advisable to use a No. 4 wire for the common return, its diameter being 0·2043in., area 0·03278 square inch, and resistance for 50 miles 63·8 ohms.

The resistance drop per phase wire $= 18{\cdot}65 \times 101{\cdot}5$
$= 1{,}893$ volts,

and resistance drop in common return $= (\sqrt{2} \times 18{\cdot}65) \times 63\,8$
$= 1{,}682$ volts.

Keeping the wires still 54·6in. apart, the coefficient of self-induction for each of the phase wires will be

$$L_2 = 0{\cdot}1089 \text{ henry},$$

the reactance $x_2 = p\,L_2 = 34{\cdot}2$ ohms,

and reactance drop $= x_2\,I_2 = 637{\cdot}83$ volts.

Similarly, for the common return

$$L_{2m} = 0{\cdot}1026 \text{ henry},$$

$$x_{2m} = 32{\cdot}23 \text{ ohms},$$

and reactance drop $= 850$ volts.

The vector diagram is given in Fig. 6. It is assumed that the receiver pressures O E_1 and O E_1' are equal

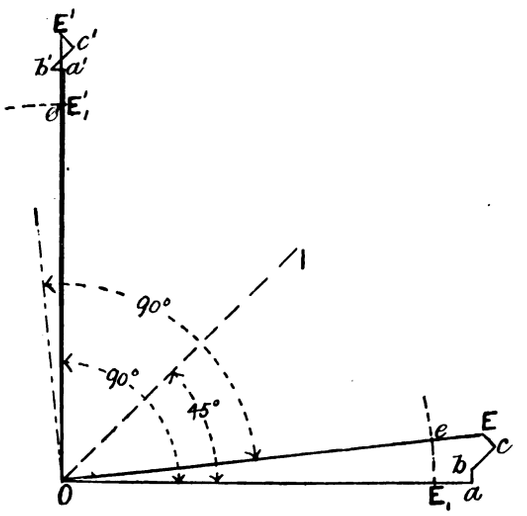

Fig. 6.

(20,000 volts) and are in quadrature (90deg.) with one another. $E_1\,a = E_1'\,a' = 1{,}893$ volts are in phase with O E_1 and O E_1', whilst the reactance volts $a\,b = a'\,b' = 637{\cdot}8$ volts; these refer to the phase wires. Since the current in the common return wire is the vector sum of the equal line currents, its direction will be O I, making 45deg. with O E_1 and O E_1'; consequently the vector representing the resistance drop for the common return will be parallel to O I, and $b\,c = b'\,c' = 1{,}682$ volts, whilst c E and c' E' (normal to O I and equal to 850 volts) represent the corresponding reactance drop in the common return. The generator pressures for the two phases are given by O E and O E' respectively, and it will be observed that they are not equal and are not in quadrature with each other. Thus, from the diagram O E = 22,625 volts and O E' = 23,625 volts, and the drop in volts in one phase is 2,625 volts and in the other 3,625 volts. Such conditions could scarcely be realised in practice, as the generator pressures O E and O E' would approximately be equal and in quadrature with each other. The assumption that the receiver pressures were equal and in quadrature, as made above, is wrong, and the more correct way is to begin with equal generator pressures in quadrature with one another, and making use of the data previously obtained, to work backwards, as it were, and determine the receiver pressures in the manner explained below in the second case with a common return. It is obvious that, although economy of copper is secured by adopting the two-phase three-wire system, the regulation of the line is defective.

Second Case. With Power Factor = 0·80 (α).—In this case the actual power received = ·80 × apparent power.

$$\therefore \text{ current in each phase} = I_3 = \frac{500 \times 746}{\cdot 8 \times 20{,}000}$$
$$= 23{\cdot}31 \text{ amperes}.$$

Also

$$I_3^2\,R_3 = \frac{15}{100} \times 500 \times 746,$$

and

$$R_3 = \frac{\cdot 66}{10^6} \times \frac{100 \times 5{,}280 \times 12}{\cdot 7{,}854\,d_3^2}.$$

$$\therefore d_3 = \cdot 2274\text{in.}$$

A No. 3 wire is ·2,294in. in diameter, so this size may be selected, its area being 0·04133 square inch, and the resistance for 100 miles is 128·8 ohms. Therefore, the resistance drop = 3002·3 volts, and placing the wires 54·6in. apart, the coefficient of self-induction per phase is

$$L_3 = 0{\cdot}2105 \text{ henry},$$

the reactance $x_3 = 66{\cdot}13$ ohms,

and reactance drop $= 1540{\cdot}9$ volts.

The vector diagram is given in Fig. 7, from which the generator E.M.F. per phase is found to be 23,375 volts, and the drop in volts in the line 3,375 volts.

Second Case. With Power Factor = 0·80 (β).—With three wires, one of which is a common return wire, the current in each phase wire will be the same as with four wires,

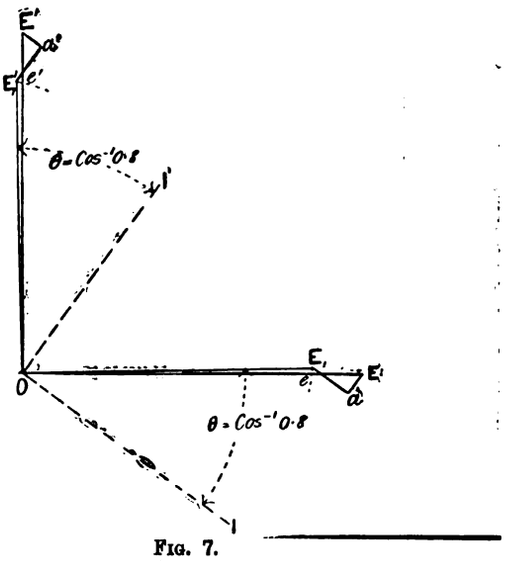

Fig. 7.

and $I_4 = 23{\cdot}31$ amperes, but with the same percentage line loss the size of the wire will be different. In this case

$$2\,I_4^2\,R_4 + (\sqrt{2}\,I_4)^2\,\frac{R_4}{\sqrt{2}} = \frac{15}{100} \times 1{,}000 \times 746,$$

in which R_4 is the resistance of each phase wire 50 miles in length; and since the common return wire must have an area of cross-section $\sqrt{2}$ times that of each phase wire, its resistance will be $\frac{R_4}{\sqrt{2}}$ for 50 miles. Let d_4 and d_{4m} be the diameters of these wires; then

Digitized by Google

$$R_4 = \frac{\cdot 66}{10^6} \times \frac{50 \times 5{,}280 \times 12}{\cdot 7854\ d_4^2}.$$

But $$I_4^2\, R_4\, \{2 + \sqrt{2}\} = 150 \times 746,$$

and $$I_4 = 23{\cdot}31 \text{ amperes.}$$

$$\therefore\ d_4 = 0{\cdot}211\text{in.}$$

The nearest gauge wire is No. 4, which is 0·2043in. in diameter and 0·03278 square inch in area. The resistance for 50 miles is 63·78 ohms. To determine the size of the common return wire we have $\sqrt{2} \times \cdot 03278 = 0{\cdot}04635$ square inch, which corresponds to a diameter of 0·243in.; the nearest gauge wire to this is No. 2, which has a diameter of 0·2576in., an area of 0·0521 square inch, and a resistance of 40·13 ohms for 50 miles.

The resistance drop per phase wire is therefore

$$I_4\, R_4 = 23{\cdot}31 \times 63{\cdot}78 = 1{,}486{\cdot}7 \text{ volts,}$$

and the resistance drop in the common return is

$$\sqrt{2}\, I_4\, R_{4m} = \sqrt{2} \times 23{\cdot}31 \times 40{\cdot}13 = 1{,}322{\cdot}7 \text{ volts.}$$

The coefficient of self-induction per phase wire is

$$L_4 = \frac{50 \times 5{,}280}{1{,}000} \left\{ 15{\cdot}24 + 140{\cdot}366 \log \frac{54{\cdot}6}{\cdot 102} \right\} \times 10^{-6}$$

$$= 0{\cdot}1026 \text{ henry.}$$

The reactance $x_4 = 2\pi \sim L_4 = 32{\cdot}23$ ohms,

$\therefore$ reactance drop per phase wire is

$$x_4\, I_4 = 32{\cdot}23 \times 23{\cdot}31 = 751{\cdot}28 \text{ volts.}$$

Similarly for the common return wire we have

$$L_{4m} = \frac{50 \times 5{,}280}{1{,}000} \left\{ 15{\cdot}24 + 140{\cdot}366 \log \frac{54{\cdot}6}{\cdot 1288} \right\} \times 10^{-6}$$

$$= 0{\cdot}1012 \text{ henry.}$$

The reactance $x_{4m} = 31{\cdot}8$ ohms,

$\therefore$ reactance drop in common return wire is

$$x_{4m}\, I_{4m} = 31{\cdot}8 \times \sqrt{2} \times 23{\cdot}31 = 1{,}048 \text{ volts.}$$

If we assume that the receiver pressures are equal and in quadrature (90deg.) with one another, the vector diagram, given in Fig. 8, is readily constructed. Since the power

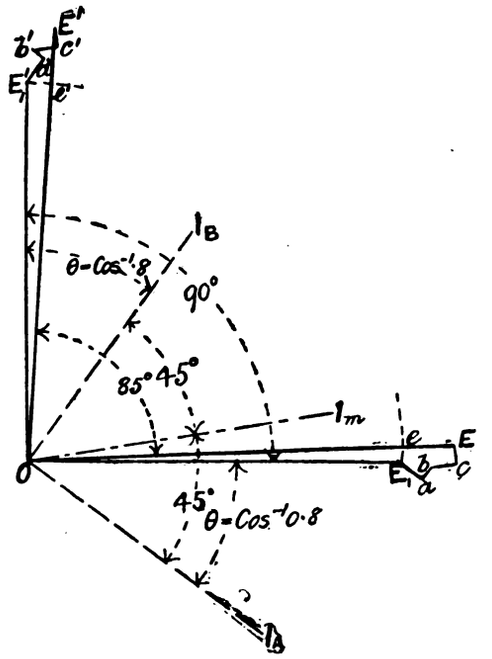

FIG. 8.

factor of the load is 0·8, the receiver pressures (20,000 volts), O E_1 and O E_1', make equal angles with O I_A and O I_B, the two phase currents, also assumed to be in quadrature with each other. $E_1\ a$ and $E_1'\ a'$ represent 1,486 volts, the resistance drop per phase wire, and are parallel to O I_A and O I_B respectively. The reactance drop per phase wire is represented by $a\ b = a'\ b' = 751{\cdot}2$ volts. The phase of the current in the common return is given by the vector O I_m; consequently the vector for the resistance drop in the common return is given by $b\ c = b'\ c' = 1{,}322{\cdot}7$ volts, parallel to O I_m, whilst the reactance drop for the common return is given by $c\ E = c'\ E' = 1{,}048$ volts. The generator pressure for the two phases are given by O E and O E^1 respectively, and it will be found that these are not equal and are not in quadrature. For instance, O E = 22,750 volts and O E' = 23,000 volts, and the phase relationship of the two generator pressures is 85deg. The drop in volts in the respective phase wires are 2,750 and 3,000 volts. These conditions do not correspond with those obtained in practice, and the method of working backwards to obtain the diagram for the working conditions is as follows. Let us assume that the generator pressure for each phase is 22,875 volts—*i e*, the mean of the pressures 22,750 and 23,000 volts as determined above. Now, the percentage drop in volts in one phase is

$$\frac{2{,}750}{22{,}750} \times 100 = \frac{1{,}100}{91} = 12{\cdot}1 \text{ per cent.}$$

and in the other phase is

$$\frac{3{,}000}{23{,}000} \times 100 = \frac{300}{23} = 13 \text{ per cent.}$$

Therefore, with the same percentage drop in the lines and a generator pressure of 22,875 volts, the drop in volts in the first phase will be

$$\epsilon_1 = \frac{11}{91} \times 22{,}875 = 2{,}765 \text{ volts,}$$

and the resulting receiver E.M.F. will be

$$22{,}875 - 2{,}765 = 20{,}110 \text{ volts.}$$

In the second phase we have

$$\epsilon_2 = \frac{3}{23} \times 22{,}875 = 2{,}984 \text{ volts,}$$

and the resulting receiver E.M.F. will be

$$22{,}875 - 2{,}994 = 19{,}891 \text{ volts.}$$

It will simplify matters if we assume that the currents in the two phase wires change proportionately with the receiver pressures, consequently the currents in the phase wires will be respectively

$$I_A' = 23{\cdot}31 \times \frac{20{,}110}{20{,}000} = 23{\cdot}438 \text{ amperes.}$$

$$I_B' = 23{\cdot}31 \times \frac{19{,}891}{20{,}000} = 23{\cdot}183 \text{ amperes.}$$

The resistances and reactances of the conductors are as before, therefore

Resistance drop in phase wire A = $23{\cdot}438 \times 63{\cdot}78$
$= 1{,}494{\cdot}876$ volts.

Resistance drop in phase wire B = $23{\cdot}183 \times 63{\cdot}78$
$= 1{,}478{\cdot}6$ volts.

Similarly the reactance drop in phase wire A = $23{\cdot}438 \times 32{\cdot}23$
$= 755{\cdot}4$ volts.

The reactance drop in phase wire B = $23{\cdot}183 \times 32{\cdot}23$
$= 747{\cdot}2$ volts.

As regards the new construction of the vector diagram (Fig. 9), the generator pressures are taken as being in quadrature, or, in other words, their phase relationship has been increased by 5deg., consequently the phase angle between the receiver pressures O E_1 and O E_1' and between the currents O I_A' and O I_B' must also be increased by 5deg.—*i e.*, have a phase angle of 95deg. Beginning with O I_A', representing 23·438 amperes, and O I_B', representing 23·183 amperes, making an angle of 95deg. with one another, the current in the common return wire is given by the diagonal, O I_M', of the parallelogram, and is thus found to be 31·6 amperes. Consequently

the resistance drop in the common return = $31{\cdot}6 \times 40{\cdot}13$
$= 1{,}268$ volts,

and the reactance drop in the common return = $31{\cdot}6 \times 31{\cdot}8$
$= 1{,}005$ volts

The receiver E.M.F.'s, O E_1 and O E_1', equal to 20,110 and 19,891 volts respectively, are next introduced, and making with O E_1 and O E_1' respectively an angle θ, such that $\cos\theta = 0{\cdot}8$. The diagram is completed by introducing the following vectors in the order given.

Digitized by Google

$E_1 a$ parallel to $O I_A'$	and equal to	1,494·8	volts.
$a b$ normal to $E_1 a$	,,	,,	755·4	,,
$b c$ parallel to $O I_m'$	,,	,,	1,268	,,
$c E$ normal to $b c$	,,	,,	1,005	,,
$E_1' a'$ parallel to $O I_B'$	,,	,,	1,478·6	,,
$a' b'$ normal to $E_1' a'$	,,	,,	747·2	,,
$b' c'$ parallel to $O I_m'$	,,	,,	1,268	,,
$c' E'$ normal to $b' c'$	,,	,,	1,005	,,

O E and O E', the respective generator pressures, will then be found to be practically equal to one another (and = 22,875 volts) and to make an angle of 90deg. with each other. The bad regulating qualities of a three-wire two-phase transmission system are still obvious, and it will be

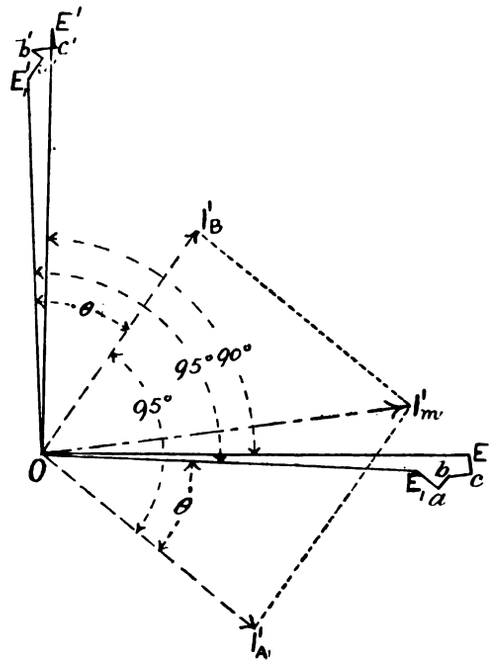

FIG. 9.

observed that the receiver pressures are unequal—*i.e.*, 20,110 and 19,891 volts—and it may be remarked that several engineers are now discarding this system of transmission.

(To be continued.)

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

LINE CALCULATION.

SIR,—I have been looking through answers to Question 795 in the issue of Aug. 4, and it seems to me that two of the answers printed are seriously incorrect.

1. *Answer by E. P. Hollis.*—In Table A the interest and depreciation is taken as 8 per cent. on the *total cost* of the 40 miles of line. This is, I think, incorrect, for according to Kelvin's law the 8 per cent. should only be taken "on that part of the capital outlay which is proportional to the area of the conductor"; in this particular case the copper conductors only. As the cost of poles, brackets, insulators, and erection will remain constant for at least six sizes of conductor nearest the one wanted, so that the 8 per cent. should be reckoned on the cost of the copper wires only. The cost of waste energy per year given in the table as $\frac{£12·3}{A}$ is not right, inasmuch as it takes no account of the load factor, which is the *sine qua non* of the whole business. The real cost of waste energy per annum would be $\frac{£12·3}{A} \times (\text{load factor})^2$. Curiously enough, the conclusion arrived at from Table A as to the size of wire to use is fairly correct, the two mistakes neutralising one another.

Fourth Answer by "Newcastle."—In working out the wasted units per annum, this writer assumes a 35 per cent. load factor and makes the units wasted 144,000. This, however, is incorrect, as the units wasted are *not* proportional to the load factor, but to the *square* of the load factor—a very different matter. So that the wasted units would really be about 36,700, and, therefore, the annual loss £115, instead of £450 given in the answer. Also from this it follows that the sectional area of No. 9's wire, instead of being too small as stated, is too large, and the curve of "cost of units wasted" in the diagram is quite out of place. In reckoning out the total loss in the line for 8 S.W.G. wire, the figure is given as 24·9 kw. This is wrong, for the resistance of 40 miles of 8's wire is 85·66 ohms, and not 59·5 ohms, the figure taken in the example; so that the total $C^2 R$ loss is 54 kw. instead of 24·9 kw. The lost volts are also obtained from a formula (which I think is incorrect) as 1,490. The lost volts—*i.e.*, loss between any two wires—are equal to $\frac{\text{total energy loss}}{1\frac{1}{2} C} = 2{,}490$ volts; or by Ohm's law $C = \frac{E}{R}$, where R is resistance of 80 miles of No. 8's wire and C is current per wire.—Yours, etc.,

Aug. 15, 1905. DUPLICATOR.

THE SWITCHMAN'S INVOCATION TO ELECTRA.

BY SIMPLEX.

Ho most divinest fair!
That makest hall thy slaves go through the 'oops
Like a performin' bear
Or other animals in circus troupes.
Bow down thy beaucheous hear!
List to the throbbin' sorrow of my song!
Tell me my rise is near,
Yea, gently whisper "Now we shan't be long."

Ah, what a weary while
I've punched the volts abart this bloomin' board!
Ho with what shockin' guile
The chief with promises my mind hath stored!
Too late I know the truth!
I shan't get any rise at all this year.
Mourn then my wasted youth,
And w'en I snuff it, drop a pitying tear!

Electra! 'Art of stone!
Wilt thou not melt in pity for thy slave?
Jest listen 'ow I groan!
Stretch forth thy 'ansum arms thy worm to save.
Hear then this shuddering sob—
Find me a screw, and let me have the tip.
Send me a better job.
This sort of thing gives me the 'orrid pip!

PERSONAL.

Mr. H. E. Osborne, engineer-in-charge to the Watford Urban District Council, has been appointed to a similar position by the Dover Corporation, and his place has been filled by Mr. C. S. Taylor, of Erith.

Mr. J. Mordy Lambe, formerly borough electrical engineer of Kimberley, has been appointed to a similar position in Johannesburg, owing to the retirement of Mr. C. W. Moore on account of his health, which we are glad to hear is now improving. With regard to this appointment 55 applications were received through London agents, and 21 from persons resident in South Africa. Mr. Lambe was one of a short leet of four. The others were E. B. Thornhill (Taunton), E. A. Browning, and W. J. Dale, the two latter giving addresses at Streatham. The Johannesburg Council have appointed Mr. J. A. McMullen station engineer.

The Acton District Council have appointed Mr. Harry A. Harding, of Leatherhead, assistant electrical engineer at a salary of £130 per annum.

The staff of the Aberdeen Corporation electricity department last week entertained Mr. J. Wilson and Mr. D. J. Hawkes at dinner on the occasion of their leaving Aberdeen, Mr. Wilson to fill an appointment with the Clyde Valley Electricity Supply Co., and Mr. Hawkes with Siemens Bros., London.

A DOCTRINE OF NEGATION.

The British Association has in the past done good work, and may continue so to do in the future, but the good work consists only of a few grains of corn among the mountainous heap of chaff which has been turned out. The Rev. W. Cunningham, presiding over the economic section, has delivered an address entitled "Unconscious Assumptions in Economics," wherein, by quotations, he shows that the classic economists were very much at sea when touching upon the development of new countries or colonies. The reverend gentleman seems to us to have fallen somewhat into the error of his predecessors, and unconsciously assumes that the conditions which exist at the time he argues are the conditions that will continue to exist through all time. Now, if we only think for a moment of the conditions of the world's affairs which existed when some of the classic economists wrote, we find a set of conditions differing very considerably from those prevailing to-day. The great factor in the change has been the increased facilities for intercommunication. Says the presidential address: "The men of the classical period of economics who devoted themselves to the study of new countries were not in a position to deal with the subject properly, and their writings seem singularly lacking in grasp." Adam Smith did not realise, nor could he be expected to realise, that America would ever be brought within a week's journey, or that communication almost instantaneous would be held with that country. He had no idea of a system which would permit of Australasian mutton being sold in the markets of Britain. But we know this is a daily operation, and the market for Australasian mutton has been largely increased thereby. A demand usually increases but to be supplied, and a larger demand means development of the tract of the world's surface from which the demand is supplied. The classic economists did not assume too much—they argued from the facts they knew and from changes they deemed possible and probable. Take a couple of mineral operations and see the difference. New Zealand teems with coal, but its coal is not being rapidly developed, nor does this mineral wealth play a very great part in the development of the country. The Transvaal possesses great stores of gold and diamonds. Its development has been largely due to these mineral riches. In one case, that of coal in New Zealand, there is but a small market; in the other, that of gold and diamonds, the market is as extensive as the world, and the demand enormous. Thus we see differing conditions lead to development in different ways. The facilitating of intercommunication increases the market which demands a certain product, and production increases accordingly. The ruling factor is demand, and this the classic economists knew. What they did not know was that telegraphy and the steam-engine would play so large a part in increasing the demand by increasing the area over which the product could be supplied. Our author pertinently says, "Economic experts are not even yet acquainted with philosophical principles as to the manner in which communities ought to develop, and, therefore, we are not justified in pretending to train up a young country in the economic way it should go." This is but another way of saying we do not know and we cannot foretell the conditions which will exist, hence no hard-and-fast lines of development can in the abstract be indicated. It must not be assumed that discussions into the domain of economics are uninteresting to the engineer. This is certainly not the case, and especially in an old-established community like our own. The development of the younger communities can be and must be assisted from the older community, hence a large part of our trade.

Ships, engines, railways, machinery are required for the supply of mutton or gold. The suppliers of these products look elsewhere than to themselves for these things, and naturally obtain them from the older and more greatly developed countries.

WIRELESS TELEGRAPHY MEASUREMENTS.*

BY W DUDDELL, MEMBER, AND J. E. TAYLOR, ASSOCIATE MEMBER.

(Concluded from page 240.)

Adjustments of Transmitting Apparatus.—To successfully carry out measurements of the strength of oscillations set up in a receiver antenna under the various conditions set out in this paper necessitates very great care in the working of the transmitter to avoid irregularities of action. In spite of all precautions some variations were unavoidable, but they were not of such a nature as would invalidate results obtained if other conditions remained constant. To produce the most regular and uniform strength of oscillations in the transmitter wire, it was necessary to give attention to the following points: (1) To use an interrupter which is capable of uniform and consistent operation. (2) To use a definite adjustment of the spark or discharge gap in relation to the power applied. This gap must not be too short, or erratic multiple sparking is obtained, nor must it be too long, or frequent "misfires" or spark failures then result. (3) To use sparking knobs of a size suited to the capacity and length of spark adopted. (4) To keep the insulation of all parts of the high-tension system as nearly perfect as possible, and minimise all brush discharges. (5) To use Leyden jars with good metallic coatings. The nitrous fumes developed during use cause rapid deterioration of unprotected tinfoil coatings. The jars used were completely varnished over the inside coatings with shellac varnish, except where connections were made. (6) To keep the height and relative positions of the antenna wires, earth leads, and earth netting constant.

The most difficult points to negotiate were those connected with the adjustment of the spark-gap, as, having taken all precautions, sparks would occasionally misfire or vary in intensity. Owing, however, to the method adopted in observing and recording the deflections obtained on the receiving instrument, occasional "misfires" did not necessarily affect the readings, because for each reading a continuous series of sparks, lasting half a minute, was used, and any erratic momentary deviations in the deflections were not considered in recording the mean deflection, the steady value only being taken into account. Apart from this effect, mysterious changes in the spark were often observed. When the transmitter oscillations, as indicated on the thermal ammeter, were below par, it would often be possible to resuscitate the sparks by slightly moistening the discharge knobs. It was also found that for relatively large capacities, such as that used for wave No. 3, it was impossible to get uniform results with 1in. diameter brass knobs on the discharger when using a short gap. If, however, the 1in. knobs were replaced by ¼in. brass rods with rounded ends, a much more uniform effect was obtained for short sparks of, say, ⅛in. to ¼in., but for longer sparks the knobs were preferable. On the other hand, with the smaller capacities used, the knobs were found suitable under all conditions of spark-lengths adopted in the experiments, whilst the rods gave poor results.

As regards the form of interrupter, the most consistent results were undoubtedly given by the mercury turbine if run at speeds less than about 1,500 r.p.m. At higher speeds there is a tendency to churn up the alcohol and mercury, forming a mercury emulsion, which seriously interferes with the action of the interrupter. It is also very important to keep the resistance of the primary circuit through the spark coil as low as possible, and adjust the current strength by regulating the voltage applied rather than by inserting resistance. The Grisson interrupter gives a much more rapid series of sparks, however, and, therefore produces a larger deflection on the receiver. The relative positions of the antenna wire and earth netting is very important. The strongest oscillations were obtained when the antenna was immediately over the middle of the earth netting. In experiments with a transmitter antenna of an inverted L-shape, the reading on the thermal ammeter in the transmitter wire increased from a mean of 0·464 ampere, with the earth netting displaced about five yards from its symmetrical position under the antenna, to a mean of 0·496 ampere with the netting immediately under, an increase of about 7 per cent. in current strength.

Tuning.—The tuning between the exciting circuit and the transmitter antenna, although well defined, was not of the sharpness which can be developed by improved methods of coupling. It was such that the number of turns in the auxiliary inductance used for tuning the antenna might be varied to the extent of about 15 or 20 per cent. without greatly affecting the strength of oscillations. The tuning of the receiver antenna was rather more definite than this. For the different waves used the adjustment of tuning inductances with full height of antennæ was as follows:

	Turns of Inductance in Antennæ.	
	Transmitter.	Receiver.
Wave No. 1	12	8
,, ,, 2	18	12
,, ,, 3	40	32

The total lengths of wire from the top of the antennæ to the earth netting in each case were:

	Transmitter wire.	Receiver wire.
Wave No. 1	96ft.	92ft.
,, ,, 2	102ft.	96ft.
,, ,, 3	124ft.	116ft.

It was from these figures that the wave-lengths were deduced on the assumption that the wave was about four times the length of the wire used in the radiating system. For wave No. 3 it might be thought that a length of 480ft. would be more consistent with the lengths of wire than the 500ft. assumed, but in this case considerable amounts of inductance were inserted in the antennæ, and it appeared reasonable to assume that in such a case the inductance would be increased in a greater ratio than the number of turns of wire on the drum. The reason for the receiver wire being shorter than the transmitter is not very clear, but the difference is within the limits of experimental error. It is, however, possible that the oscillating current in the antenna flowed to earth *viâ* the spark gap and the Leyden jars, rather than *viâ* the Leyden jar inductance spiral. If this was the case, it would be necessary to add more inductance in series with the antenna to tune it to the same period as the oscillatory exciting circuit, hence the longer length of wire. This method of computing the wave-length in terms of the length of wire used is open to error where large aerial capacities are concerned, but in the present instance, where the antennæ were formed of single wires, it may be taken as sufficiently accurate for a rough approximation. As an aid to tuning and for indicating the strength of oscillations in the transmitting system, the pivoted thermo-ammeters proved very satisfactory, and they have the great advantage, as compared with hot-wire ammeters of the usual description, that the resistance and inductance which they introduce into the system is practically negligible. As regards the sensibility of the suspended form of instrument used at the receiver, it may be taken that good readable deflections could always be obtained so long as the strength of signals was sufficient to act upon the coherer receiver with the slow-sparking interrupter at the transmitter. To increase the range of sensibility beyond this point merely requires an increase of the rate of sparking. In connection with the question of tuning, a brief series of tests were made at the transmitter to determine whether the Duddell thermo-ammeter used was inserted in the best position in the radiating system. Accordingly one ammeter was fixed permanently in position A, as shown in the diagram (Fig. 1), whilst another was inserted in successive positions *a*, *b*, *c*, *d*, and *e*. The results obtained were as follows:

Position.	Current, amps.
a	0·300
b	0·337
c	0·344
d	0·355
e	0·338

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

It will thus be seen that whilst the ammeter was normally connected up in the correct position the actual antinode of current was not on the wire netting. From this point of view the netting appears to act as a capacity rather than an actual earth connection.

In conclusion, the authors wish it to be understood that the general scheme of operations and many valuable practical details of the experiments were directly due to Mr. Gavey, through whose good offices the necessary official permission has been obtained to publish these results, which they trust may be of some use in advancing the cause of wireless telegraphy.

THE MAINTENANCE OF COMMUTATORS AND BRUSHES.

BY S. LEES.

The subject of the following article may appear, perhaps, to some readers to be rather simple and uninteresting, but it is, nevertheless, a most important one to which too much attention cannot be given if the maximum efficiency and economy in the running of direct-current machinery is to be obtained with the minimum of expense. Even in these enlightened days, there are many central stations of large size (the writer speaks from actual experience) where, while money is literally thrown away on expensive test-room equipments—potentiometers, with their numerous adjuncts, photometers, balances, etc., in fact, no end of standard instruments of various kinds—it is considered quite

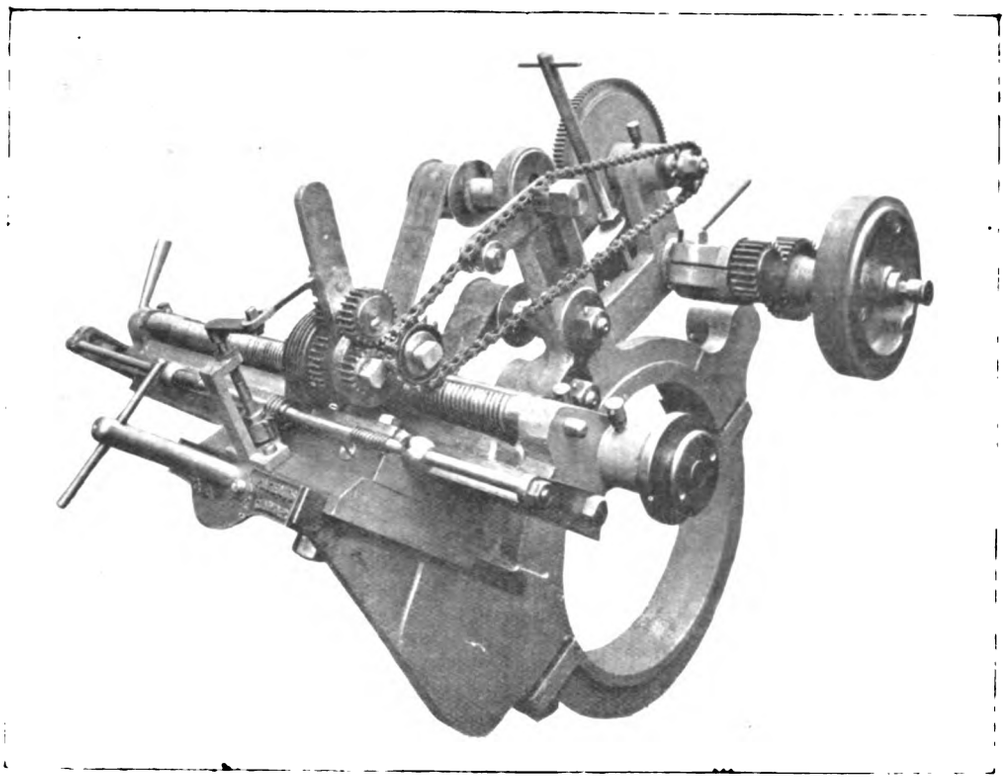

FIG. 1.

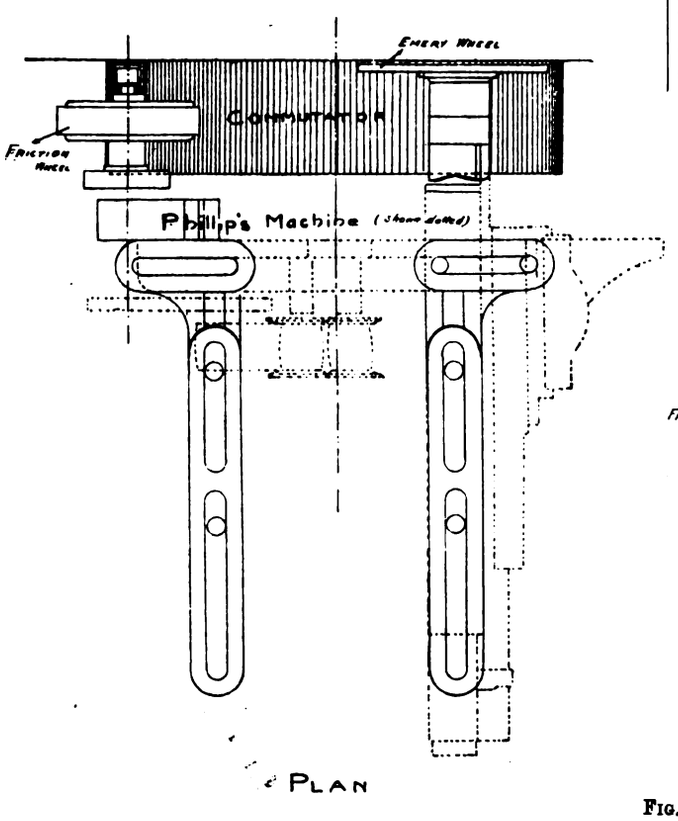

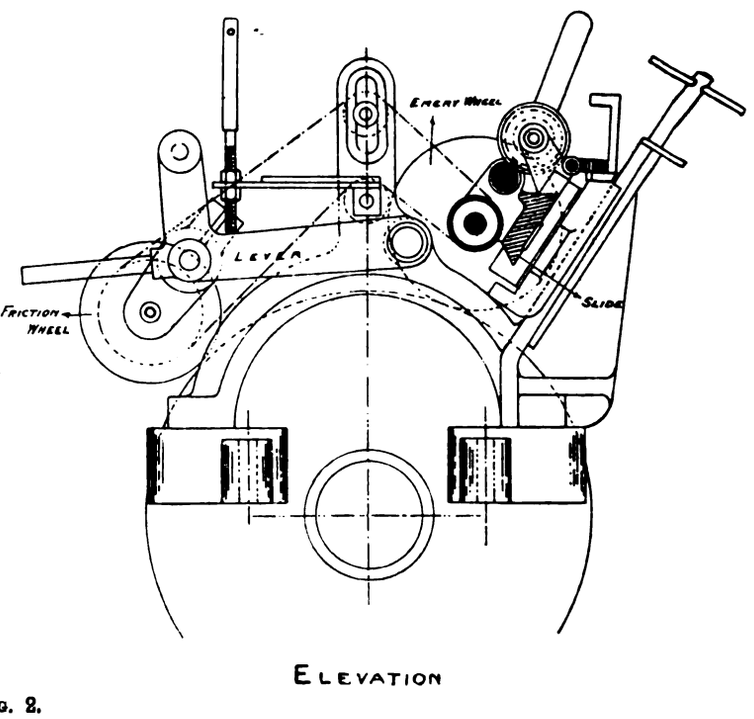

FIG. 2.

Digitized by Google

unnecessary to provide anything in the way of tools for the cleaning and truing up of the commutators.

Formerly, it was usual when a commutator had been allowed to get into such a bad state that running was impossible unless accompanied by a fine display of pyrotechnics, to tide matters over by putting a file on the commutator; as, with many of the older types of machines it was an impossibility to rig up a slide rest and skim up

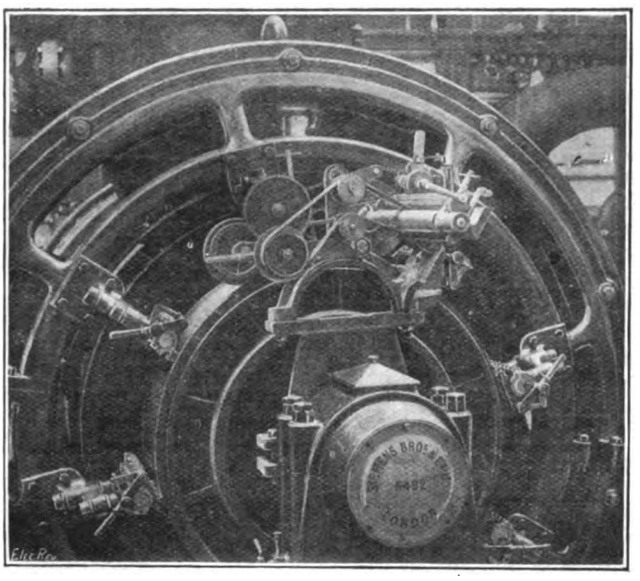

FIG. 3.

the commutator in position, and to take out an armature of four or five tons weight was often no easy matter—the lay-out of the plant in some of the older stations left much to be desired, these things being understood better at the present day—to say nothing of the inconvenience caused through the armature having to be sent away to some shop to be turned up, as very few of the stations of 10 or 15 years ago enjoyed the luxury of a lathe.

mutator very uneven, aggravating sparking by causing the brushes to jump, and resulting in increased wear of both the commutator and brushes.

The writer recalls an experience he encountered about eight years ago at a large electricity works in Yorkshire. The commutators of nearly all the generators (some 17 in number, varying in size from 150 kw. to 600 kw.) were in a very bad state, and one of the writer's first jobs on first taking up duties was the truing up (by file) of the commutators of two of the 150-kw. sets. The machines were of the bipolar type, having three copper gauze brushes to each holder. The brushes of dissimilar polarity had been placed exactly in a line with each other, owing to which the commutator had become worn down in the form of three grooves, the flanges thereto standing up about $\frac{1}{4}$in. all round from the rest of the commutator. The sets were direct-coupled, and, viewed from the machine end, ran counter-clockwise, rendering the filing nearly all left-hand work. The works did not boast a lathe, and the machines could not be spared out of service long enough to allow of the armatures being sent away.

Of the two methods of truing up commutators—viz, turning and grinding—the writer is of opinion that, taken all round, grinding makes the most satisfactory job. In order to get the best results by turning, the operator requires to have a thorough working knowledge of turning, and the writer's experience has taught him that a really good mechanic is the exception rather than the rule in most installations, not excepting even central stations. Where possible, it is preferable to true up the commutator in position. Hard-drawn copper as used for commutator bars is queer stuff to work, and as the bars have a tendency to spring when passing under the tool the cutting speed should not exceed about 90ft. per minute. With high-speed direct-coupled sets having engines of the two-crank type—particularly single-acting engines—it is sometimes a rather difficult matter to get even turning at these low rates of speed. A tool-holder to take tool steel of V section is very suitable for commutator work, as, in case of breakage, grinding only is required. Light cuts should be taken as the tool is liable to *dig in*. After the finishing cut is taken the speed may be increased slightly, and a file run over the commutator. Before finally polishing with emery cloth the

FRONT ELEVATION

FIG. 4.

Nowadays there is no excuse for treating commutators in this barbarous manner, although some engineers still stick to the idea that the presence of slight flats does not necessitate the truing up of the whole commutator. That this idea is quite erroneous may be easily proved by carefully calipering the commutator after the flats have been *filed out*. The small flats have been removed only to give way to larger ones, thus leaving the whole surface of the commutator should be carefully examined all over and any metal which may be found bridging across the mica insulation between the segments carefully removed. The final polishing is best done with a special tool as described later on.

There are two types of commutator grinding machines—viz, (1) driven direct from the commutator to be trued up, (2) driven by belt from separate source, usually a small

Digitized by Google

motor. Figs. 1, 2, 3, and 4, illustrative of type 1, represent the grinding machine of the Phillips Commutator Grinder Company, Limited, of London. Fig. 1 is a general view of an automatic machine having a clamp arrangement for fixing round the brush-rocker journal. Where no rockers are used the same machine can be fixed round the nose of the outer bearing. Distance rings of different sizes are used when necessary to fit various sizes of rockers. When inconvenient the bottom half-ring is dispensed with, and the machine is bolted to arms supported from the cover bolts (Fig. 2), and when the diameter of the commutator is extra large the arms are raised by means of distance pieces, or they are bolted to the platform of a casting clamped round the nose of the bearing, as illustrated in Fig. 3. Fig. 4 shows the machine as sometimes supported by means of two cast-iron arms fixed to magnet ring, and in some cases to the brush ring (when sufficiently strong). Here the machine is shown mounted on the top of a commutator 8ft. in diameter. The Phillips light hand-feed machine, which is used chiefly for small dynamos (exciters, boosters, etc.), is made to *true-up* commutators from 3in. to 9in. diameter and 6in. wide (across face). The heavier hand-feed machine is made stronger to carry longer slides to true-up commutators from 6in. to 12in. diameter to 10in. wide. This type of machine is specially suitable for dynamos on board ship (but they can be used otherwise), which, as a rule, are erected close to the bulkheads, allowing but little room for working. In working the grinding spindle is driven direct by means of a specially prepared rubber friction wheel running on the commutator. The grinding wheel moves to and fro across the face of the commutator, and in all except the hand-feed machines is automatically reversed at each end, being so constructed that stops can be set as in a planing machine, grinding the surface right up to the connecting wires and back to the edge. The grinding wheel should, of course, run in the opposite direction to the commutator.

A commutator truing machine possessing some novel features has recently been placed on the market by Jordan Bros., of New York, U.S.A. It is of the direct-driven type, the grinding wheel spindle being driven by means of a round belt passing round the commutator or armature shaft. The grinding wheel spindle is slotted to allow of lateral movement of the wheel across the face of the commutator. The feed is controlled by hand, the depth of cut being set by means of an eccentric gear. The grinding wheel is specially made for commutator work, as it is claimed that no substance which would be injurious to commutators enters into its composition. The machine is provided with suitable clamps for affixing to the rocker journal or framework of the generator or motor. An illustrated detailed description of the machine appeared in the June number of the *American Electrician*.

(To be continued.)

APPOINTMENTS VACANT.

Assistant Engineer, Handsworth Urban District Council. Salary £100 per annum. Applications by 30th inst.

Junior Demonstrator in Physics and Electrical Engineering to the L.C.C. School of Marine Engineering, Poplar. Salary at the rate of 10s. 6d. an evening. Applications by 10 a.m. on Sept. 18. See advertisement.

Head of the Department of Physics and Electrical Engineering, Portsmouth Education Committee. Salary, £175 per annum. Application by Sept. 4. See advertisement.

Draughtsman for switchboards. Apply to Box H 91, *Electrical Engineer* office. See advertisement.

Draughtsman for transformers. Apply to Box Y 2, *Electrical Engineer* office.

Electrical Units and Standards.—It is reported that the Elektrotechnische Reichsanstalt has called a conference, preparatory to the meeting of the International Commission of Electrical Units and Standards. This course is to be highly commended, and is in accord with the recommendations of the St. Louis International Electrical Congress, which advocated that the differences in the laws of various countries in reference to electrical units should be considered by an international commission. This conference is expected to be held at the end of next month, and invitations have been sent to the Governments of Great Britain, the United States, France, Austro-Hungary, and Belgium.

PRACTICAL STANDARDS FOR ELECTRICAL MEASUREMENTS.

The following is the report of the committee of the British Association, recently presented in South Africa, on experiments for improving the construction of practical standards for electrical measurements. Lord Rayleigh is chairman of the committee, and Dr. R. T. Glazebrook secretary.

The committee are glad to report that satisfactory progress has been made during the year with the ampere balance. The weighing mechanism was taken over from the maker shortly after the last meeting of the association, and the work on the coils completed at the National Physical Laboratory. The labour involved in insulating the two wires on the large cylinders was very great. Each wire consists of about 90 turns of about 105cm. circumference. Thus each wire is about 95m. in length, and the two are along their whole length about $\frac{1}{10}$mm. apart. In the coils as finally set up the insulation resistance between these two wires is measured in thousands of megohms, and is thus amply sufficient. The cost of the balance has amounted to £302. 6s., the excess over the £300 granted for the purpose being met out of the general fund at the disposal of the committee. Calculations of the force to be expected between the coils when carrying one ampere have been made by Mr. Mather and Mr. F. E. Smith, of the National Physical Laboratory, and are in close agreement.

The designs from which the balance has been made are the work of Mr. Mather, and originally it was contemplated that the balance would be set up at the City and Guilds Central Institute in Exhibition-road. At a meeting of the committee held on March 31, 1905, however, this decision was modified, and the following minute agreed to: "That the ampere balance remains for the present at the National Physical Laboratory, and that a determination of the ampere be made with it there under the supervision of Prof. Ayrton and Mr. Mather, steps being taken to connect closely with the determination and with any notification of the results the names of the late Prof. J. V. Jones, Prof. Ayrton, and Mr. Mather, to whom the design of the instrument is entirely due." Accordingly, the balance has been set up at the National Physical Laboratory, and a number of preliminary tests have been made. Particulars of some of these follow.

Ampere Balance.—The weighing mechanism of the balance was erected by Mr. L. Oertling at the National Physical Laboratory in March of the present year, and the electrical equipment was completed immediately afterwards. The four coils of bare copper wire wound on marble cylinders have given complete satisfaction, the ellipticity and conicality of each being very small. The average ellipticity is such that the diameters of the ellipse differ in length by about 10 micron, while the average conicality is approximately represented by a difference between the mean diameters of two sections 13cm. apart (the axial length of one coil) of about 12 micron. The contour of the cylinders is very well known, and the mean diameter has been measured with a probable error not greater than 0·001 per cent. This knowledge enables the calculation of the mutual induction between two coils to be made with great accuracy. Preliminary observations with a current of nominal value, one ampere, were made at various times during April and May, the first set of such observations determining the temperature to which the coils are raised by a continuous steady current, the magnitude of the disturbances arising from convection currents, the influence of the silver strips, and the nature of other disturbances. The convection currents give some trouble, but the experiments already carried out indicate that a change of 0·001 per cent. in a current of nominal value one ampere will be detectable. The balance acts conveniently as an indicator of the magnetic permeability of the marble and metal parts of which it is constructed, and it is satisfactory to know that the permeability of these parts does not differ from unity by a measurable amount, and cannot therefore influence the final results. Early observations showed that the concentric cable employed in the leads to the balance

Digitized by Google

was faulty, some of the internal strands being broken, and the variable contacts thus resulting prevented a steady current from being obtained. Fresh concentric cable is being inserted, which should enable the final observations to be speedily made.

Apparatus for the Determination of "g."—The three half-second pendulums (the property of the Board of Education, and which were used in the last Antarctic expedition) have been swung at Kew and at the National Physical Laboratory in the room where the balance is erected. The observations are being continued. When all the constants have been determined and the observations with the balance are complete, it will be necessary to consider the means by which the result is to be given to the world. The current may be reproduced either by means of the silver voltameter or by means of a standard cell and a standard resistance. The silver voltameter is being investigated at the National Physical Laboratory, and a comparison of the accuracies of reproduction would perhaps influence the choice. The committee were represented at the International Electrical Congress at St. Louis last year by Prof. Perry and the secretary. The resolutions passed at the Cambridge meeting of the committee (see report for 1904) as to certain questions proposed for discussion were laid before the congress, and after discussion the following reports were unanimously accepted:

Committee of the Chamber of Delegates on International Electromagnetic Units.

The sub-committee appointed Sept. 13, 1904, beg leave to suggest that the Chamber of Delegates should adopt the following report: It appears from papers laid before the International Electrical Congress and from the discussion that there are considerable discrepancies between the laws relating to electrical units, or their interpretations, in the various countries represented, which, in the opinion of the Chamber, require consideration with a view to securing practical uniformity. Other questions bearing on nomenclature and the determination of units and standards have also been raised, on which, in the opinion of the Chamber, it is desirable to have international agreement. The Chamber of Delegates considers that these and similar questions could best be dealt with by an international commission representing the Governments concerned. Such a commission might, in the first instance, be appointed by those countries in which legislation on electric units has been adopted, and consist of, say, two members from each country. Provision should be made for securing the adhesion of other countries prepared to adopt the conclusions of the commission. The Chamber of Delegates approves such a plan, and requests its members to bring this report before their respective Governments. It is hoped that if the recommendation of the Chamber of Delegates be adopted by the Governments represented the commission may eventually become a permanent one.

Committee of the Chamber of Delegates on International Standardisation.

The committee of the Chamber of Delegates on the standardisation of machinery begs to report as follows: That steps should be taken to secure the co-operation of the technical societies of the world by the appointment of a representative commission to consider the question of the standardisation of the nomenclature and ratings of electrical apparatus and machinery. If the above recommendation meets the approval of the Chamber of Delegates it is suggested by your committee that much of the work could be accomplished by correspondence in the first instance, and by the appointment of a general secretary to preserve the records and crystallise the points of disagreement, if any, which may arise between the methods in vogue in the different countries interested. It is hoped that if the recommendation of the Chamber of Delegates be adopted the commission may eventually become a permanent one.

The first of these reports, relating to the summoning of an international congress on electrical units, is now under the consideration of his Majesty's Government. Meanwhile a preliminary conference of representatives of standardising laboratories and others interested in the determination of electrical units has been summoned by the president of the Reichsanstalt to meet in Berlin in the autumn. Lord Rayleigh and the secretary have received invitations to be present. The object of this conference is stated to be that the institutions which are concerned in maintaining the accuracy of electrical measurements in conjunction with those scientists who have devoted especial attention to this field of work should exchange opinions, and, if possible, come to an agreement as to the measures which must be taken in order to obtain the international uniformity in electrical units and measurements which is desired. It is thus preliminary to the more formal consideration of the subject which would be the work of the international congress. One of the important questions which will be discussed will be the specification of some form of standard cell. Work on this matter has gone on in America and at the National Physical Laboratory, and an appendix to the report by Mr. Smith contains a provisional specification. It is suggested that persons interested in the matter might help by setting up cells in accordance with this specification and submitting them for test at the laboratory. Of the grant made to the committee in 1904 a balance of £3. 4s. 10d. remains. The work which remains to be done on the standard cell and with the ampere balance will all involve considerable expense, and to meet this the committee ask for reappointment, with a grant of £25 in addition to the balance now in their hands.

Appendix I.

On the Preparation of a Cadmium Cell.

BY F. E. SMITH.

(From the National Physical Laboratory.)

The research on standard cells has been continued at the National Physical Laboratory on the lines indicated in the last report to the association. Taken as a whole, the results are very satisfactory, but it is thought desirable to still continue the observations on some of the older cells before publishing the results in detail. Mr. G. A. Hulett, of Michigan, has completed a chemical research on mercurous sulphate, which throws considerable light on the anomalies reported to the association last year. Very slight changes can still, however, be traced to this salt, but fortunately they are of no commercial significance. The 12½ per cent. amalgam also produces slight variations in the E.M.F. of the cell. These, again, are commercially unimportant, and a manner of overcoming them in cells employed at a standards laboratory is indicated in this paper. The latter cells are set up with an amalgam entirely liquid at 0deg. C. At this stage of the research it is thought desirable to describe the methods by which the materials of the cell can be best prepared in the light of present information, and an appeal is made to those interested in the subject to set up one or more cells by these methods and submit them for comparison with the standards of the National Physical Laboratory. More light will thus be thrown on the slight discrepancies already referred to, and the degree of accuracy with which the cell can be constructed will be established. In this way it is hoped to specify a cell for commercial purposes accurate at all ordinary English working temperatures to 1 part in 2,000, applying no temperature correction, or to 1 part in 10,000 if the temperature correction be applied. In the specification which follows there are four methods of preparing the mercurous sulphate. The first of these is due to Prof. H. S. Carhart, Mr. G. A. Hulett, and Dr. Wolff, jun.; the main features of the second method were suggested by Mr. Swinburne to Dr. Glazebrook, while the third and fourth methods have resulted from some experiments at the National Physical Laboratory. It is suggested that one only of these methods be eventually employed; the observations on submitted cells will largely determine the choice.

Preparation of Materials for a Standard Cadmium Cell.

1. *Mercury.*—The commercial mercury should be squeezed through wash leather and passed in the finely divided condition in which it emerges, first through dilute nitric acid (1 to 6 of water) and mercurous nitrate solution, and afterwards through distilled water, both liquids being conveniently contained in long glass tubes. The mercury is then to be twice distilled *in vacuo*. Mercury suspected of abnormal contamination should not be employed.

2. *Amalgam.* Type A.—This is a 12½ per cent. amalgam, and is intended for all commercial cells. The method of preparation is practically identical with that used by Prof. Carhart. A current is passed from a thick rod of pure commercial cadmium to distilled mercury, the intervening liquid being cadmium sulphate solution rendered slightly acid with a few drops of H_2SO_4. The cathode is weighed

Digitized by Google

before deposition takes place, and again afterwards, the percentage of cadmium in the amalgam being thus calculable. More than the requisite amount should always be deposited, and the percentage reduced to 12½ by the addition of more mercury. The fall of potential from anode to cathode should not exceed 0·3 volt. To prevent the anode slime having access to the cathode it is desirable to surround the anode with a small porous pot, as in the Richards silver voltameter, or to place a small crystallising dish beneath it for the anode powder to settle in. Contact with the cathode is made with a platinum wire sealed into a glass tube so as to protect it from direct contact with the cadmium sulphate solution, and a rough estimate of the quantity of cadmium deposited is obtained from the readings of an ammeter placed in the circuit. The amalgam so prepared, together with the mercury added to reduce the percentage of cadmium to 12½, is now heated on a water bath and stirred so as to ensure homogeneity, some cadmium sulphate solution still flooding the surface. It is then cooled, and the acid sulphate removed, neutral cadmium sulphate solution taking the place of the latter, and consisting of saturated solution plus an equal volume of distilled water. This 12½ per cent. amalgam is then ready for use and is entirely liquid at a temperature approximating to 60deg. C.

Type B.—This amalgam is liquid at the temperature of melting ice, and is intended for cells of a slightly better type than those made with the 12½ per cent. amalgam. The cells may be used at a higher temperature than 0deg C., but they are not intended to be so used, as their temperature coefficient is about 0·043 per cent. per rise in temperature of 1deg. C. The cells are primarily intended for standardising laboratories, and their E.M.F. at 0deg. C. is equal to the E M F. of the cells prepared with the A amalgam if this latter E M.F. is corrected to 0deg. C. with the temperature coefficient formula of the cell. This is equivalent to saying that if an A cell was in a steady condition at 0deg. C., and nothing abnormal occurred, its E M F. would be identical with that of a B cell at 0deg. C. It is not wise, however, to use a 12½ per cent. amalgam cell at low temperatures. An 8 per cent. amalgam may be so used, but its upward range (with a small temperature coefficient) is lower than that of the 12½ per cent. amalgam cell. For commercial purposes probably the 12½ per cent. amalgam will be of most service. To prepare the type B amalgam, take some of that previously prepared and add sufficient mercury to reduce the percentage of cadmium to 3. The amalgam will now be entirely liquid at ordinary working temperatures. On cooling, a crystalline amalgam separates from the liquid, and will continue to do so as the temperature is lowered. Cool the amalgam to the temperature of melting ice and remove the mother liquid; this is the amalgam desired. It is important that the temperature be truly that of melting ice, and that no solid is removed. For convenience the 3 per cent. amalgam may be placed in a tubular vessel well surrounded with ice shavings; a long very fine capillary tube reaches to the base of this vessel, and through it the liquid at 0deg. C. is removed by suction. Some solid must be left behind, or otherwise there is no certainty of saturation. Throughout all the operations neutral cadmium sulphate solution must cover the surface of the amalgam and wet all vessels, tubes, etc, through which the amalgam passes. Otherwise the amalgam will leave a "tail," and its composition may possibly be thereby changed.

3. *Cadmium Sulphate Crystals and Solution.* — Procure commercially pure cadmium sulphate ($CdSO_48/3H_2O$). Dissolve in about 1¼ times its weight of distilled water, agitating either continuously for about six hours or occasionally for two or three days. Filter through a fine-grained filter paper so as to ensure a clear solution, which should then be placed in a number of crystallising dishes and evaporation allowed to take place slowly at a temperature not exceeding 35deg. C., when, provided that dust be excluded, many transparent crystals of $CdSo_48/3H_2O$ will result. These should be prevented as much as possible from adhering to one another by removing the liquid to other dishes as soon as the crystals are of such a size that most of them are in contact. In this way about five-sixths of the liquid may be evaporated, the mother liquid being employed for a preliminary washing of the mercurous sulphate, the manufacture of which is afterwards described. The crystals of cadmium sulphate so obtained should be washed with successive small quantities of distilled water until after standing for five minutes no trace of acidity can be detected with congo red. The crystals, still moist, may then be transferred to a stock bottle. To prepare the final solution agitation with distilled water is recommended as before, the temperature being preferably 5 deg. or 10deg. higher than the normal temperature, so as to ensure saturation. On no account should cadmium hydroxide be employed to neutralise the first solution, which is invariably acid; nor, indeed, should any attempt be made to neutralise the solution except by crystallisation.

4 *Mercurous Sulphate.*—The preparation in each case is to be conducted in a darkened room.

(*a*) *Electrolytic Method.*—Pure distilled mercury forms the anode and platinum foil the cathode, the electrolyte being dilute sulphuric acid (one part by volume of concentrated acid to five parts of distilled water). The mercury is preferably placed in the base of a large flat-bottomed beaker, and about 20 times its volume of the dilute acid added. Contact with the mercury is effected by means of a platinum wire passing through a glass tube, while the cathode is suspended in the upper portion of the liquid. During the electrolysis the electrolyte must be continually stirred, an L-shaped glass stirrer being most efficient, the L portion being placed near the surface of the mercury. A current density of about 0·01 ampere may be employed. The salt so prepared is treated as per Note A.

(*b*) Precipitation method, mercurous nitrate and sulphuric acid being employed. Add strong nitric acid to a little pure mercury contained in a crystallising dish, and place in a draught chamber until the action is over. If any mercury remains, adds more acid and continue to do so until the mercury has completely disappeared and a strongly acid solution assured. Prepare dilute H_2SO_4 (1 to 4 by volume), allow to cool, and then add the acid nitrate solution drop by drop, keeping the mixture violently agitated. Mercurous sulphate is precipitated, which should be filtered and treated as per Note A. No more nitrate solution must be added to the dilute H_2SO_4 than will suffice to neutralise 30 per cent. of the H_2SO_4 present. The maximum amount it is permissible to add may be estimated by taking a small portion of the dilute H_2SO_4 and adding the nitrate solution until no further precipitation results. The proportion of nitrate solution to dilute H_2SO_4 in such circumstances must be reduced to one-third its value for the preparation of mercurous sulphate by method *b*.

(*c*) Precipitation method, strong and dilute sulphuric acid being employed. Purchased mercurous sulphate is warmed with pure strong H_2SO_4 and a little mercury to a temperature of about 150deg. C. for about 10 minutes, the operation being conducted in an evaporating dish covered with a clock glass and the mixture kept well stirred. The suspended matter is then allowed to settle, the hot liquid cooling sufficiently meanwhile for the vessel to be handled with comfort. The clear acid is then poured into dilute H_2SO_4 (1 to 6), when crystalline mercurous sulphate separates out. About 10 times the bulk of dilute acid should be employed, and to avoid spitting the hot liquid should be poured through a funnel, having its stem immersed in the dilute acid. The mixture is well stirred, cooled, and filtered, and the salt treated as per Note A. As the operation yields but a small quantity of the salt it is advisable to repeat several times

(*d*) By means of Nordhausen sulphuric acid. Place distilled mercury in the bottom of a beaker or bottle to the depth of about 3mm. Add about four times its volume of Nordhausen sulphuric acid and stir well, keeping the mouth of the bottle closed as much as possible, as the acid fumes are very unpleasant. Mercurous sulphate is formed in the cold and appears in the crystalline form after a few minutes. Allow the operation to continue until the acid strength has been considerably diminished; then pour into dilute H_2SO_4 (1 to 6). Considerable spitting always occurs, so that caution is necessary. Proceed with the product as per Note A.

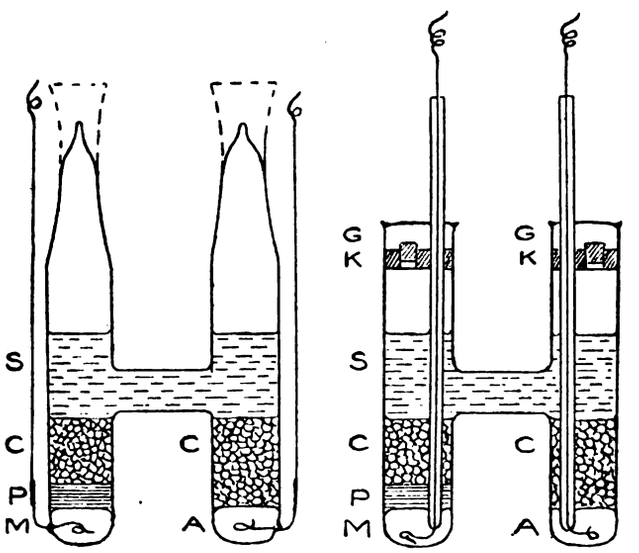
Note A.—The mercurous sulphate obtained by the foregoing methods is first agitated with dilute H_2SO_4 (1 to 6)

Digitized by Google

and distilled mercury. It is then filtered (a small Gooch crucible and filter flask are convenient), and the greater part of the mercury removed, as it interferes with the filtering. The salt is next washed with small quantities of saturated cadmium sulphate solution until free from acid. For the first few washings some of the first acid solution may be employed, but the final washings must be made with a little of the neutral solution. Trouble is often experienced in ridding the salt prepared with Nordhausen sulphuric acid from all trace of acidity, and it is preferable to wash five or six times with the cadmium sulphate solution, and then place in a bottle together with a little of the solution, shaking from time to time and filtering again in a few days. The acidity of the washing liquid should be tested with congo red. Instead of washing with cadmium sulphate solution, sulphuric ether (water free) may be employed.

The Mercurous Sulphate Paste.—Some cadmium sulphate crystals are ground in an agate mortar with a little cadmium sulphate solution; about one-quarter their bulk of pure mercury is then added and two volumes of the acid-free mercurous sulphate, the whole being well mixed with cadmium sulphate solution so as to form a thin paste.

The Form of Cell.—The H form of cell due to Lord Rayleigh is the most convenient, and is in general use. Two patterns have been adopted. In Fig. 1 a form is



FIGS 1 AND 2.—M, Mercury; A, Amalgam; P, Paste; C, Cadmium Sulphate Crystals; S, Saturated Solution of Cadmium Sulphate; K, Cork; G, Marine Glue.

shown in which the electrodes are sealed into the lower ends of the two vertical limbs, while in the form shown in Fig. 2 the electrodes pass through glass tubes, into the lower ends of which they are sealed. Form 1 can be hermetically sealed, and is intended to be immersed in an insulating liquid. Form 2 is sealed with marine glue, and may be immersed in ice or water. The hermetical sealing of form 1 was suggested by Lord Rayleigh and by Prof. Carhart. The glass tubes through which the electrodes are introduced in form 2 pass through corks which have been previously boiled in water and soaked in cadmium sulphate solution; in addition to the hole allowing of the passage of the electrodes, a second hole is bored through these corks for the passage of small glass pipettes. After the cell is filled these additional holes are fitted with small corks, and the cell is finally sealed with marine glue. The position of the various parts is shown in the figure. (Both forms of glass vessels are stocked by Mr. A. C. Cossor, of 54, Farringdon-road, E.C.) In filling the vessels it is convenient to use small pipettes made of two glass tubes, the one about 3in. long and $\frac{1}{2}$in. in diameter, and the other about 2in. long and $\frac{1}{3}$in. in diameter. If the larger tube has one end drawn out in the form of a cone, a junction is easily made. The amalgam of type A is melted over a water bath (its surface being flooded with dilute cadmium sulphate solution), and is introduced by means of a previously warmed pipette into one of the limbs. After the amalgam has solidified this limb should be washed out with a little fresh cadmium sulphate solution. If the amalgam of type B is used this washing is unnecessary. The mercury is next introduced into the other limb, then the paste, using if necessary a tiny glass rod as a piston through the pipette, and afterwards a thick layer of finely-pounded crystals is introduced into each limb. Saturated cadmium sulphate solution is finally added. The cells are then to be exposed in a warm room for a week or more to allow some of the liquid to evaporate, and so loosely cement together the fine crystals. This crystalline plug keeps the contents in their proper places, and enables the cell to be transmitted through the post. The sealing of the cells is next completed, care being taken not to abnormally heat the contents.

Cells which are submitted for comparison with the standards of the National Physical Laboratory should be accompanied with the following particulars: (1) maker's name and address; (2) name of the firms from whom the chemicals used in the manufacture of the materials were purchased (this information is only required so that the number of different sources of the materials can be estimated); (3) number of the method employed in the manufacture of the mercurous sulphate; (4) type of cadmium amalgam used; (5) notes on any peculiarities observed in the preparations.

REDUCTION OF BEARING FRICTION.

Since the electric motor has come into general use, the question of the economical transmission of power has come more prominently before manufacturers, and the more up-to-date concerns have been quick to appreciate the possibility of effecting large economies by eliminating the large amount of frictional load which always exists with long heavy lines of shafting.

The electric motor does away with the necessity of a great deal of shafting, especially the heavy main lines. At the same time, there are many cases where it is more economical to employ various lines of shafting, each separately driven by an electric motor, than to have each and every machine especially equipped with a motor of its own. When a manufacturer can stand in front of an electrical instrument and observe as easily as he tells the time of day from his watch just exactly how much power he is wasting and absolutely throwing away on the friction on his line shafting, he is very apt to welcome any suggestion which will tend to materially reduce this friction. There are, of course, anti-friction bearings of various makes on the market, all possessing more or less merit and demerit. Ball bearings for shafting have not been successful for two reasons, principally owing to the cost of the same and the difficulty of applying them, since balls must have hard steel races to run in in order that the bearing may have any durability. The second reason is that the balls are not so reliable as they might be, since one is likely to split at any time and ruin the entire bearing. Solid rollers have been used for many years off and on, but these bearings, like the ball bearings, in order to be thoroughly durable, must be very nicely made, hardened, and ground throughout, which, of course, means expense, and they also require sleeves on the shaft, which means a lot of labour and trouble in the fixing. Expense again stands in the way of the general adoption of these bearings for general line shafting transmission. There are, of course, cheaper grades of solid roller bearings manufactured, but those who have experimented with them have found that running solid rollers directly on soft-steel shafting is not a practicable or desirable thing to do.

For the past 10 years we learn that the Hyatt flexible roller bearing has been used with a marked degree of success for a multitude of purpose, chiefly among them for line shafting. These rollers, as shown in the accompanying illustration (Fig. 1), are practically helical springs, being wound from a ribbon of steel into spiral form. Their diameter and the size of the steel from which they are made are varied according to the speed and load under which the rollers are to operate. They are not put through a hardening process, but are constructed of a grade of steel especially made for the purpose, which is hard and very tough. The rollers are wound in a special machine constructed for the purpose and within very fine limits of absolute size. The fact that they are flexible and elastic makes it possible to operate them on the ordinary soft-steel shafting which is in general use, without wearing either the shafting or the rollers to any appreciable degree. The rollers are held in position round the shaft in a brass or steel cage (Fig. 2), with bars at proper intervals to keep the roller practically parallel with the shaft. If, however, a roller is permitted to get very slightly out of line it does not do any damage, either to itself or the shafting, due to the fact that it is flexible; whereas in the case of a solid roller, if it becomes the least bit out of parallel

Digitized by Google

with the shaft, it immediately begins to wear heavily on the ends and is very likely to slip. This kind of thing very soon renders a solid roller bearing useless.

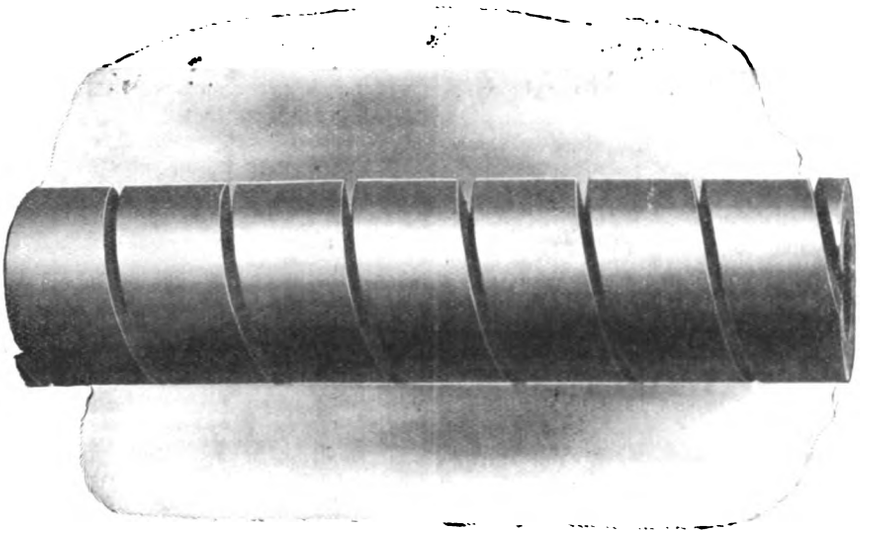


FIG. 1.

Regarding the efficiency of roller bearings in general, it has been found by very careful tests that the Hyatt flexible roller is 50 per cent. higher in efficiency than the ordinary solid roller

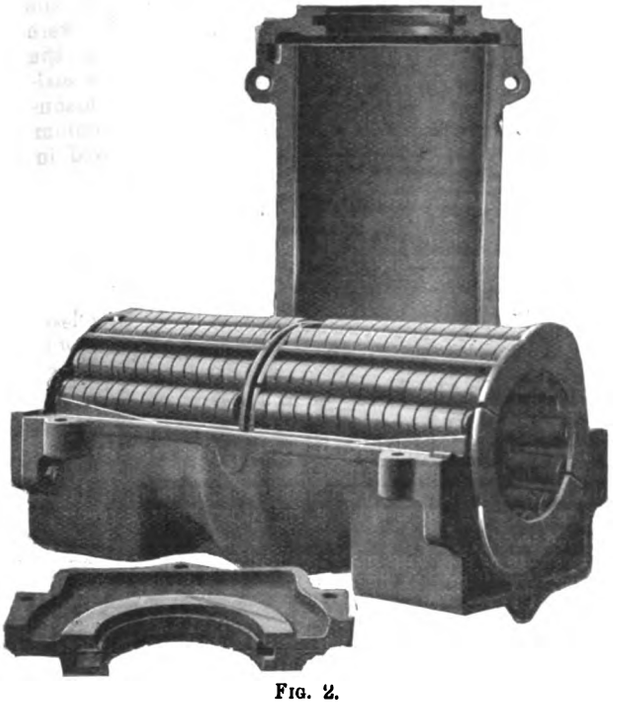

FIG. 2.

made of the same grade of steel when both are subjected to exactly the same conditions. In actual service on line shafting it has been proved by careful experiment that the flexible roller

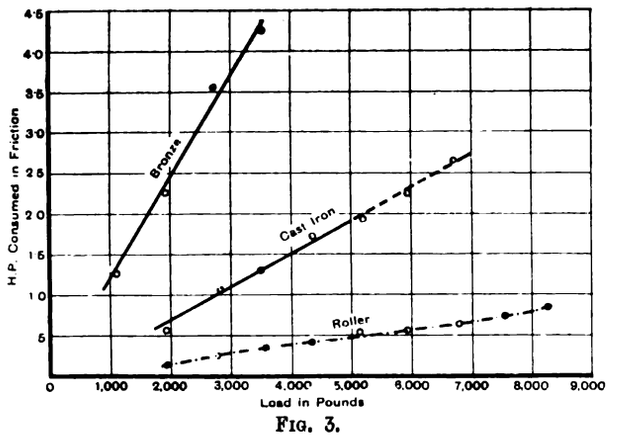

FIG. 3.

bearing will save from 50 to 75 per cent. of the frictional load found to exist with ordinary brass or white metal bearings. The heavier the shafting the greater the saving is in proportion.

We reproduce herewith two charts (Figs. 3 and 4) which embody the results obtained in a very careful test recently made by a prominent engineer to determine the relative merits of the Hyatt flexible roller bearing, bronze, babbitt, and cast-iron bearings. It will be seen from these charts that the results are uniformly in favour of the flexible roller, and very much so.

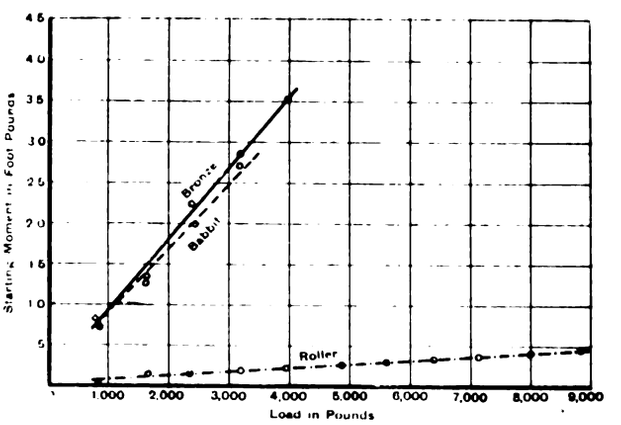

FIG. 4.

The first of these shows the horse-power consumed when running with varied loads on the different bearings. The second (Fig. 4) indicates the force required when starting, and it is remarkable how much the rollers reduce the starting effort. Many of the leading manufacturing concerns in England have already availed themselves of the opportunity of economising power by the use of these bearings, which in every instance appear to be giving excellent results.

Detailed information and particulars regarding the same may be had from the Hyatt Roller Bearing Company, 47, Victoria-street, London, S.W.

TRADE NOTICES AND NOVELTIES.

Machine versus Hand Firing.

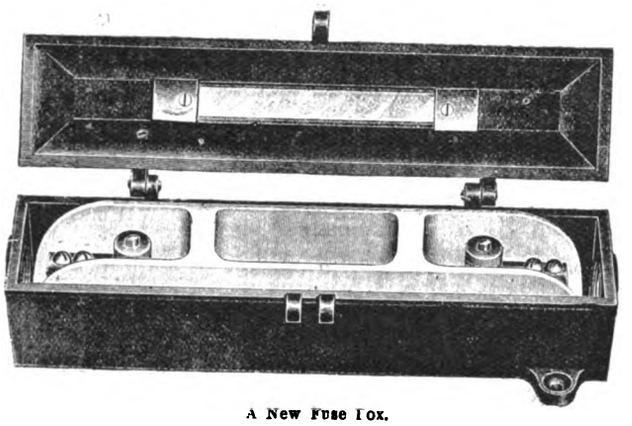
From Messrs. E. Bennis and Co., Limited, 28, Victoria-street, S.W., we have received a copy of a little booklet they have had prepared, showing comparative tests between hand firing and machine firing with "Bennis" stokers. The results are highly favourable to the latter. Thus the figures in one case show a saving of 44·1d., or 57½ per cent., per 1,000 gallons of water evaporated in favour of machine firing. For the hand-firing test Holroyd engine coal at 10s. 4½d. per ton was used, and for the stoker test Haigh Moor pea slack and smudge mixed, of lower calorific value, at 7s. per ton. The record sheet further shows that there was a total absence of black smoke during the stoker test—not so, however, during hand firing. In another example it is shown that the extra evaporation obtained per pound of coal by the Bennis stoker over hand firing amounted to 18·9 per cent., Haunchwood D.S. nuts being used for both tests. The gain varies, of course, with the class of fuel employed. This point is emphasised by another set of figures, whence it appears that with black shale smudge the extra evaporation obtained per pound used by Bennis stoker and furnace was 70·9 per

Digitized by Google

cent., and with low main peas 34·8 per cent. In order to estimate these results at their true value it is necessary to know all the conditions of the tests. These are given in the booklet in question, but we must leave the reader to weigh them in detail.

A New Fuse Box.

The fuse box illustrated herewith represents a type which the Metallic Seamless Tube Company, Limited, Wiggin-street, Birmingham, are putting on the market. These boxes have been designed to meet the requirements of the various supply stations, insurance rules, etc., for 250 and 500 volts, and have a clear break of 3in. for 250 volts and 6in. for 500 volts between the terminals. The boxes are suitable either for screwing



A New Fuse Box.

direct, or can be fitted with insulating nipples as may be required. They are designed so that the same form of terminal can be used either for connecting the cables by pinching screws, soldering, or both. In the 250-volt boxes one china bridge, and in the 500-volt boxes two china bridges, with slot for the fuses, are placed between the terminals. These bridges serve to prevent arching over, and also strengthen the porcelain channel.

A Useful Combination Instrument.

The accompanying diagram shows the connections of a Ferranti combined indicating and discriminating wattmeter and idle-current ammeter for a three-phase circuit. This instrument is constructed on the same principle as the firm's induction type indicating wattmeter. In addition, however, to indicating the total power flowing in the circuit, it serves as a discriminating device to give warning should the generator commence motoring. A centre zero is provided, the indications of the pointer to the right of this measuring the power being generated. Should, however, the pointer move to the left of zero, the switchboard attendant knows at once that something is causing the generator to motor, and he takes steps accordingly. Besides the above, the instrument will also indicate the idle or wattless current flowing in

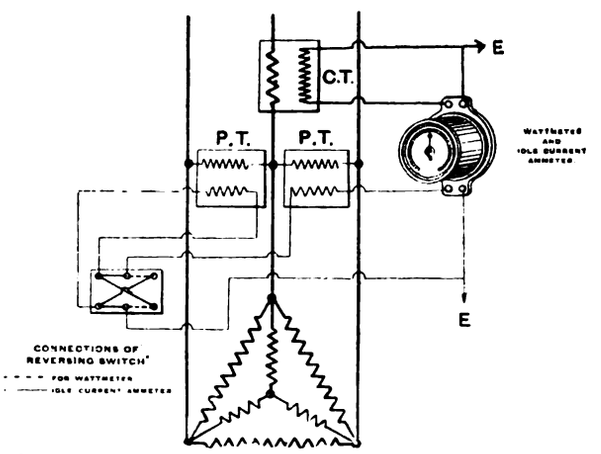


Diagram of Connections to Ferranti Wattmeter and Idle-Current Ammeter.

the circuit. The meter has two scales. The upper one, printed in black ink, is the watt scale, and the lower one, printed in red ink, is the scale of wattless amperes, to the left of the zero indicating a leading current, and to the right of the zero a lagging current. The change over from one scale to the other is effected by pressing the knob of a small reversing switch connected in the low-tension leads of the potential transformer. This switch is so arranged that when pressure is removed from the knob it automatically flies back to the position in which the instrument reads watts. Thus from time to time the switchboard attendant presses the knob and observes the value of the idle current in the circuit, and alters the excitation, etc., accordingly. The necessity of a separate power-factor indicator or idle-current ammeter is hereby avoided, with consequent lowering of cost. Reverting to the diagram, it will be noticed that two potential transformers are necessary.

Catalogues, etc., Received.

Single-Phase Motors.—From Mr. E. Brook, Threadneedle-street, Huddersfield, we have an illustrated list of single-phase motors ranging in output from 10 h.p. to ⅓ h.p.

Testing Machinery.—Some interesting testing machines for a variety of purposes are described in the latest catalogue from Messrs. W. and T. Avery, Limited, Soho Foundry, Birmingham.

Steam Fittings.—"Steam dryers" and "exhaust valves" are dealt with respectively in two lists recently issued by Messrs. J. Hopkinson and Co., Limited, Britannia Works, Huddersfield, and not previously acknowledged in these columns. The high reputation which Messrs. Hopkinson have won for steam fittings of all kinds is a guarantee of the excellence of those immediately in question, both as regards design and construction.

"Metallic" Steel Conduits.—The 1905 revised price-list of "metallic" steel conduits and accessories recently issued by the Metallic Seamless Tube Company, Limited, Wiggin-street, Birmingham, is a handy little volume for the pocket, and includes numerous illustrations. Particular attention is called to the company's "Grip" fittings, for which, we understand, there is a large and increasing demand. By the use of these fittings the danger of turning the tubes in screwing the nuts home, and possible damage to the insulation of the cables in consequence, is entirely avoided.

Wires and Cables, etc.—From the General Electric Company, Limited, Queen Victoria-street, E.C., we have a copy of the twelfth edition of their catalogue of wires and cables, etc. This catalogue is so well known to the trade that a detailed description of its contents would be superfluous here. Suffice it to say it includes a wide range of wires and cables for electric light, bell, and telephone work; also a large variety of brownware and porcelain insulators, of which latter the types for high-tension work are especially noteworthy; leading-in tubes and insulators, conduits, insulator ironwork, jointing materials, cleats, wiremen's tools, etc. It may be added that the general get-up of this catalogue reflects great credit on those concerned.

Fans.—Some popular types of electric fans are dealt with in a list recently issued by Messrs. Baxendale and Co., Miller-street Works, Manchester.

ST. ANNES ELECTRICITY ACCOUNTS.

The accounts of the St. Annes-on-Sea electricity department for the year ended March 31, 1905, show a total expenditure on capital account to that date of £38,605. Abstracts of the revenue account, balance-sheet, etc., are appended.

Total maximum supply demanded (kilowatts)			721
Number of public lamps			191

LEGAL INTELLIGENCE.

THEFT OF ELECTRIC CURRENT.

At the Manchester County Police Court last week Frederick Stewart, an electrician in the employ of the Trafford Park Estates, was summoned for stealing electricity, the property of the company.

The case against the defendant was that he had tapped the electric current supplied to his house before it passed through the meter, and thus obtained his light free of cost. His defence was an absolute denial of having tampered with the wires.

He was fined £5 and costs, or one month's imprisonment.

SMOKE TROUBLES.

At the Jarrow Police Court the Durham County Electrical Power Co. were summoned at the instance of the Corporation of Jarrow for having failed to comply with an order of the court made on May 18 to abate a smoke nuisance at the power station within two months from that date.

It appeared that the nuisance was not discontinued immediately, owing, the company explained, to the time occupied in making the needful alterations.

The Bench accepted this explanation, and dismissed the summons.

SIR HIRAM MAXIM ELECTRICAL AND ENGINEERING CO.

A compulsory winding up order was made against the Sir Hiram Maxim Electrical and Engineering Co., in November, 1904, and a statement of affairs has now been issued, showing total liabilities £55,481, of which £19,192 is expected to rank for dividend. The assets are valued at £49,009, and are subject to deductions of £1 057 in respect of preferential claims and £20,309 for debentures. There is consequently an estimated surplus of £8,449 in assets to meet the unsecured liabilities of the Company, but the account with the contributories disclose a deficiency of £161,949.

COMPANIES' MEETINGS AND REPORTS

FIFE ELECTRIC POWER CO.

The second annual meeting of this Company was held last week in the Townhill generating station, when occasion was taken to turn on the electric current. Originally it was intended that the first generating stations should be established at Comrie and Cowdenbeath, but in view of its nearness to a large centre of population, Townhill was chosen for the beginning of the Company's operations.

Mr. R. E. WALKER, the chairman, in moving that the directors report, balance-sheet, and auditors' report be adopted, said that while the capital expenditure had been considerable, they had a splendid asset, for they had acquired parliamentary powers to erect generating stations in different parts of Fife, so that they might be in a position to cover the whole of the county. The county was rich in minerals

Digitized by Google

and in other respects, and he hoped and believed that the company would be able in some marked way to help in the fostering of the mining and other industries, and in the realisation of the hopes which were entertained regarding the resources that lay below the soil. Having referred to the favourable situation of the generating station, he expressed confidence that an outlet for their current would be obtained, but they would have to wait patiently before they realised the benefits to the full. Favourable terms had been offered to the Dunfermline Town Council, and the laying of tramways to be worked by electricity was in prospect. A meeting is to be held in a day or two relative to application for powers to lay a tramway by an independent company. Then there was to be a naval base established at Rosyth, which would probably require at any rate a temporary supply. In conclusion, he predicted that before the five years that were allowed the debentures would be paid off.

Mr. HENRY RUFFER seconded the motion, which was unanimously adopted.

BOLCKOW, VAUGHAN, AND CO.

The directors of Messrs. Bolckow, Vaughan, and Co. report that the total expenditure upon new collieries, new blast furnace plant, electric installations machinery, and extensions during the past year was £567,564. Dividends amounting to 5 per cent. are recommended on the ordinary shares, leaving £44,224 to be carried forward.

MATHER AND PLATT.

The annual meeting of Mather and Platt was held in Manchester on Saturday, Dr. Edward Hopkinson presiding. Dividends and bonus amounting to 10 per cent. were sanctioned on the ordinary shares, £30,000 was transferred to the reserve account, bringing it up to £230,000, and £31,238 carried forward.

The CHAIRMAN observed that the year just passed had not been marked by any unusual character. They had been affected by the war in the Far East, but with the exception of the year 1903 4 the profits of the past year had been greater than in any other period during their existence. He mentioned that Sir William Mather had gone to America to investigate new engineering developments, the acquisition of which in times past had contributed largely to the prosperity of the Company.

The report was adopted, and Messrs. J. L. Holden and J. Platt were re-elected directors.

NEW COMPANIES REGISTERED.

R. W. Vicarey.—Capital, £1,500. Object: to acquire the business carried on by R. W. Vicarey and Co. at Stafford, to adopt an agreement with the said company, and to carry on in the United Kingdom the business of consulting, experimental, and analytical experts of electric storage batteries, preparers and publishers of standard specifications of acids and waters for use as electrolytes, electricians, engineers, etc.

Liens Registered.

Electric Supply Co. of Victoria (Limited), Liverpool.—Trust deed registered July 25, for £160,000 5 per cent. first mortgage debenture stock. Trustees: Trustees, Executors, and Securities Insurance Corporation, Limited; charged on certain tramway and lighting orders, all the freehold and leasehold property in the State of Victoria, the undertakings, and all other assets, present and future, including the uncalled capital.

Blackheath and Greenwich District Electric Light Co., Limited.—Lien registered Aug. 11, for £11,708 4½ per cent. debentures, part of a series not to exceed the issued and paid-up share capital; amount previously issued, £188,292; charged on the undertaking and property, present and future, including the uncalled capital.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Florianopolis (Brazil).—The Municipality require tenders for the lighting of the town by Oct. 2.

Turn-Severin (Roumania).—The Mayor invites tenders for the electric lighting of the town. Tenders by Sept. 10.

Plasencia (Spain).—The municipal authorities require tenders for an electric lighting installation. Tenders by Sept. 15.

Pontypridd.—The Urban District Council invite tenders for (Section A) permanent way. Tenders by 12 noon on Sept. 2.

Olympia 1905 Exhibition.—The Executive Committee invite tenders for the loan or hire of 300-kw. direct coupled steam set.

Limerick.—The Technical Education Committee invite tenders for electric lighting of the municipal technical schools. Tenders by Aug. 26.

Madrid.—The Public Works Department require tenders for the construction and working of an electric tramway in Zaragoza. Tenders by Sept. 12.

Swansea.—The Corporation invite tenders for switchboard, transformer pillars, transformers, switchgear, etc. Tenders by noon on Aug. 26. See advertisement in last issue.

Taunton.—The Corporation invite tenders for a water-tube (straight) marine-type boiler, superheater, economiser, pipe extensions, etc. Tenders by Sept. 2. See advertisement in last issue.

Bishop's Stortford.—The Urban District Council invite tenders for lighting such of the public streets as are at present lighted, for two or three years from Sept. 30. Tenders by 4 p.m. on Sept. 25.

Edinburgh.—Tenders are invited for the electric lighting installation at the mortuary buildings, High School Yards, Edinburgh, for the Lord Provost, Magistrates, and Council. Tenders by Sept. 11.

Larne (Ireland).—Tenders are invited for lighting the public streets and roads of the urban district of Larne by means of coal gas or electricity for three years from Aug. 1, 1906. Tenders by 10 a.m. on Sept. 2.

Alicante (Spain).—The Harbour Board (Junta des Obras del Puerto) require tenders for two electric cranes, capable of lifting 10,000 ko. and 1,500 ko. respectively. Tenders by Sept. 15. Estimate, 107,010·10 pesetas.

Chelmsford.—The Town Council invite tenders for lighting the public streets and public clock within the borough with electricity, gas, or other illuminating power for three or five years from March 25, 1906. Tenders by Sept. 8.

Paris.—The Waterworks Department of the Municipality require tenders for supply and erection of motors, pumps, and generators for the proposed waterworks at Chantilly. For particulars apply to above authority. Tenders by Oct. 12.

Glasgow.—The Corporation invite tenders for the construction of new tramways. Specification, with form of tender, can be had on application to Mr. James Dalrymple, general manager, 46, Bath-street, Glasgow. Tenders by 5 p.m. on Aug. 28.

Pembroke (Ireland).—The U.D.C. invite tenders for electricity supply mains, arc lamps and pillars, house meters, and switchboard panels. Tenders to Mr. J. C. Manly, Town Hall, Ball's Bridge, Co. Dublin, by 10.30 a.m. on Sept. 22. See advertisement.

Stalybridge.—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery, and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

Merthyr Tydfil.—Tenders are invited by the Urban District Council for the erection of refuse destructor plant capable of effectually burning 120 tons of refuse per day, together with all buildings and contingent works connected therewith. Tenders by Sept. 1.

Ashton-under-Lyne.—The Electricity Committee invite tenders for (Section A) one 500-kw. direct-current generator; (B) one water-tube boiler with superheater, to be worked in conjunction with a refuse destructor; (C) two superheaters for Lancashire boilers. Tenders by 12 noon on Sept. 2. It will be seen by a note and from an advertisement appearing among "Contracts Open" in to-day's issue, that tenders should be sent in addressed to the borough comptroller, Mr. John Neal.

Erdington.—Tenders are required for the construction of Section No. 1 of the Erdington tramways, comprising the laying of the permanent way, including copper bonding, wood block paving, and other works incidental to the laying of about 2½ miles of double-track tramway, for the Tramway Committee. Tenders to the joint engineers, Mr. Robert Green (of Messrs. Pritchard, Green, and Co.), of 37, Waterloo-street, Birmingham, and Mr. Herbert H. Humphries, engineer to the Council, Public Hall, Erdington.

Morton Banks (near Keighley).—The Keighley and Bingley Joint Hospital Board invite tenders for the following works at the isolation hospital, etc.: (1) for keeping the private telephones, wires, and apparatus, and the electric bells, wires, and apparatus at the hospital (including the small-pox hospital) in good working order and repair and properly charged for one year from Sept. 8 next; also (2) for the supplying and fixing of a lightning conductor and telephone for new diphtheria pavilion. Tenders by Sept. 4.

Municipal Board of Mussoorie (India).—The Municipal Board invite tenders for the supply, delivery, and erection at sites, in complete working order, of the following plant: (*a*) steel power pipes; (*b*) water-motors; (*c*) alternators with exciters; (*d*) switchboards with instruments and apparatus; (*e*) transformers; (*f*) induction motors; (*g*) pumps; (*h*) workshop machines. Also for the supply and delivery of the following: (*a*) bare copper wire for overhead mains; (*b*) insulators and lightning arresters; (*c*) arc and incandescent lamps; (*d*) telephone equipment; (*e*) workshop tools; (*f*) general stores. Specifications, form of tender, and general conditions can be obtained on application to Mr. C. H. Shanan, municipal electrical engineer, Municipal Office, Mussoorie, India (telegraphic address, Shanan, Mussoorie), on payment of a deposit of Rs.75 (£5), which amount will be returned on receipt of a bona fide tender. Tenders by Oct. 23.

RESULTS OF TENDERS.

Barnstaple.—The Town Council have sealed an agreement with Ashmead, Benson, and Co. for the maintenance of the accumulators at Barnstaple electric light works, at £120 a year, for five years.

Watford.—The Electricity Committee recommend the acceptance of the estimates from W. Robey for hand railing and ladders for condenser pit, amounting to £68. 10s., and from the Brush Electrical Engineering Co. for a 12 months' supply of transformers.

Ipswich.—The following tenders have been received for electric lighting the Presbyterian Church, Ipswich:

J. Pratt, jun.	£160
Mann, Egerton, and Co.	123

Stock Exchange.—The committee has ordered the Havana Electric Railway Co.'s 6,957,000dol. consolidated mortgage 5 per cent. 50-year coupon bonds of 1952 for 1,000dol. each, Nos. 1 to 6,957, to be quoted in the official list.

Digitized by Google

BUSINESS NOTES.

TRACTION.

Hastings.—The passengers for the week from Aug. 10 to 17 totalled 298,437.

Heywood.—The work of reconstruction was expected to be commenced this week.

Huddersfield.—The Corporation have adopted the proposal to pay the employés time and a quarter on Sundays.

Shildon.—The Urban District Council have been granted a year's extension of time for starting the construction of tramways.

City of Buenos Ayres Tramways.—The directors have declared an interim dividend of 2s. 6d. per share for the half-year ended June 30 last.

Geneva Tramways Co.—The traffic receipts for July amounted to £8,500. 15s., being an increase of nearly £400 over the corresponding period of last year.

Rotherham.—Through running between the Rotherham and Sheffield systems comes into force on the 1st prox., when there will probably be a 10-minute service.

Metropolitan Railway.—It is reported that on the Inner and Outer Circle the whole service of the Metropolitan Railway will be run electrically on and after Sept. 16.

Swindon.—The Town Council have informed the Rodbourne Parish Council that the electric trams cannot at present be run to the Telford-road boundary, because the Great Western Railway bridge needs altering.

Light Railways Act.—The Board of Trade have confirmed the East Sussex Light Railway (Amendment) Order, 1905, amending the East Sussex Light Railway Order, 1901, made by the Light Railway Commissioners.

Level Crossings.—At Butte, Montana, a goods train collided with a tram at a level crossing, the accident being due, it is reported, to the driver of the tram trying to cross first. There were 29 passengers killed and injured.

Wakefield.—The Corporation, in conjunction with other municipalities, have decided upon a test case in regard to the rating of light railways, and proceedings are to be instituted against the Wakefield and District Light Railway Co.

Proposed Light Railway.—A proposal to construct a light railway from Fraserburgh to Turriff meets with favour from the inhabitants. The Fraserburgh Town Council support the project, which is apparently a question of finance.

London United Tramways.—There have been complaints by residents in Kingston and the adjoining districts as to the rate of progress and the consequent increase of time for which the streets are "up," but good progress all round was reported last week.

Mirfield.—The Huddersfield Corporation were not prepared to extend their electric car service into Mirfield, and the terms they imposed upon the Woollen District Tramways Co. were considered prohibitive. It is reported that the Mirfield Engineering Co. will fill the breach with motor 'buses.

York.—The tramways company report that the receipts for the past six months amounted to £21,681, and the expenses to £21,533, leaving a balance of £148, £5 of which is to be carried to the suspense account for reconstruction of lines, and the remainder appropriated as interest on the 5 per cent. debenture stock.

Maidstone.—The reply of the Board of Trade to the application of the Maidstone Corporation to run tramways from Penenden Heath to the top of High-street, and from the top of High-street to Loose, reverses the order of the Light Railway Commissioners, but the Board are prepared to consider alternative routes.

Alpine Railways.—Two short railways for ascending the Alps are projected for the St. Moritz district. One is for a line up the comparatively easy eminence known as the Muottas Muragl, which commands a splendid view of the country. This line is expected to be ready for use next year. The second project is for a mountain railway on Mount Piz Julien.

Swansea.—Colonel Druitt, Board of Trade inspector, last week inspected the Port Tennant section of the Swansea tramway extensions. Accompanying him were the mayor (Major Sinclair), Mr. Prusmann (electrical engineer), Mr. David James (manager of the tramways company), and Mr. Schenk (harbour engineer). The trial was successful, and it was expected that the necessary permit would be forthcoming in a day or two.

Erith.—The Board of Trade inspection of the new municipal tramway system, described in this issue, was held on Monday, when the work was approved. On one section the speed has been restricted until the street at that point has been widened. Elsewhere on the system normal speeds, ranging up to 14 miles per hour, have been sanctioned. The tramways are expected to be opened to the public to-morrow, after the inaugural ceremony.

Electric Train Dangers.—Alderman Spencer, mayor of Tynemouth, speaking at a meeting of the Town Council the other day, referred to the Southport electrical railway disaster. He strongly urged an alteration in the electric trains running from North Shields to Newcastle. The present system of shutting carriage doors from the inside was a great danger to passengers in case of fire or collision. The North-Eastern Railway directors, at an interview, promised to mend it, and he hoped there would soon be a modification in this system.

Walsall.—The traffic for the four weeks ending July 30 worked out as follows: Four weeks ending July 30, 1904—number of passengers, 364,507; receipts, £2,005. 1s. 8d.; car miles run, 47,365·95; receipts per car mile run, 10·17d. Four weeks ending July 29, 1905—number of passengers, 414,357; receipts, £2,241. 8s.; car miles run, 49,661·47; receipts per car mile run, 10·83d. Arrangements have been made with the Staffordshire County Council and the Willenhall Urban District Council as to the laying of the short length of line at Willenhall, which was completed and opened for traffic in time for the Staffordshire Agricultural Show.

Leith.—The extended line between Hamilton and Larkhall was inspected last Friday by Colonel Yorke, R.E., on behalf of the Board of Trade, and found satisfactory. Councillor Lambie; Mr. G. F. Moller, general manager of tramways; Mr. John Clarke, county road surveyor; and Mr. W. H. Purdie, Hamilton burgh surveyor, accompanied the inspector. The line passes through a populous mining district, and the cars, which have been running for some time, are being well patronised. The Newhaven section has been opened to the public. There will be a limited system of ½d. fares. A further conference is to be held with the Edinburgh Tramways Company to settle through fares.

Tunstall.—At the meeting of the Urban District Council it was reported that the Board of Trade would appoint an arbitrator to determine the difference between the Potteries Electric Traction Co. and the Council regarding the proposed junction between the company's lines and the Chatterley-Whitfield Co.'s sidings. The difficulty referred to occurred through the Council consenting to the company making the junction to enable them to convey coal over their lines to their generating stations, but refusing to sanction their conveying coal for the supply of manufacturers and general customers. The clerk was instructed to take such steps as appeared necessary to oppose the tramway company's application.

Sheffield.—The report for the year ending March 25 shows that the passengers totalled 63,952,283, the large majority being 1d. fares. The receipts amounted to £240,565. The car mileage aggregated 6,049,890. The routes showing a loss are Petre-street, Pitsmoor, Springvale, Intake, Firth-park, Owlerton (both routes), Brightside, Shoreham-street, and Osgathorpe. The plough lifeguards on 88 cars have been replaced by guards of the hanging gate type. All the cars are now fitted with this type of lifeguard. The casualties totalled 1,764, including three fatalities. Claims were made in 209 cases, the compensation paid amounting to £2. 15s. 7d. per claim, from which it may be inferred that the accidents were not of a very serious character.

Portsmouth.—The Corporation tramways took only £23 less than £5,000 in 1d. fares for the week ending the 12th inst., and more good weeks are in prospect. The portion of line between Portsmouth and Cosham would probably be much more remunerative if a mutual understanding existed between the Tramway Committee and the light railway company, so that there could be a through fare to Horndean, which is a picturesque resort. At Brighton a system of conveying passengers to points of interest, with a guide to explain matters, has been introduced, 1s. being charged for a trip of over two hours, and a writer in the local Press suggests a 6d. tour of Portsmouth, comprising visits to the dockyard, Charles Dickens's birthplace, Southsea Pier, and East Southsea.

"Tube" Competition.—Lord Rathmore, presiding at the half-yearly meeting of the North London Railway Co., said there had been a decrease in the number of passengers by 1,039,941, which he attributed to the continued and strenuous competition of electric traction. Electric traction facilitated the migration from the company's districts into the country of people who found that by these means they could live further out. For the present, at all events, it was impossible for them to attempt to meet this competition by electrifying their lines, as, until electrification was instituted on the London and North-Western on the lines belonging to the company over which the North London trains ran, it would be impossible for them to electrify their lines.

Leicester.—An accident occurred on the Melbourne-road section last week. A car was being driven down Nedham-street towards the Humberstone-road, when it was met by another car which was being driven slowly in the opposite direction. The rails at this spot divide into a loop for passing purposes, but before the latter car could clear the points a collision occurred. The driver of the first car applied his brakes, but the car was descending a slope, and failed to stop in time to avoid the impact. No passengers were in either of the cars at the time, and neither of the drivers nor the conductors were hurt. The cars, however, were considerably damaged. Mr. T. R. Smith, the resident electrical engineer, states that the "down" car was examined after the collision and no defect was found in the brakes or the mechanism of the car.

Southend.—The traffic receipts from the light railway for the year ending March 31 amounted to £17,419. 4s., as compared with £15,688. 17s. last year. The working expenses were £15,098. 16s. 4d., against £13,447. 6s. 3d., and a gross profit of £2,785. 12s. 8d. was made, being an increase of £67. 6s. 11d. on last year's working. After meeting interest and instalments of loans, there was a net loss of £1,031. 18s. 10d. on the year. A letter was read from Messrs. Isaacs and Bellamy at the meeting of the Town Council asking if the Corporation would consider the question of the lease of the proposed tramways from Southend to Southminster, and a reply was sent that the Corporation had no power to allow the proposal. In connection with the proposed extension to Shoeburyness, negotiations are proceeding with Colonel Burgess as to the land along the foreshore.

The Underground.—Mr. Arthur L. Stride, managing director of the London, Tilbury, and Southend Railway, states, in a communication (dated the 21st inst.) to the *Times*: "Under the heading of 'The Electrification of the Underground Railway,' on p. 8 of your issue to-day, you announce that the East Ham branch of the District Railway was worked for the first time yesterday under the new electrification scheme. I shall be obliged if you will allow me to point out that the District Railway ends at Whitechapel Station, and that

Digitized by Google

the service inaugurated yesterday is a joint train service in the interests of the Tilbury and District Companies, from stations on the District Railway, working over the Whitechapel and Bow, which is the joint property of the two companies and from Bow to East Ham over the Tilbury and Southend line. This service will be extended to Barking as a terminus so soon as the alteration at that station is completed. There is no such thing as an East Ham branch of the District Railway."

Dewsbury.—There has for some time been an agitation for an extension of the electric tramway system at Dewsbury. By the agreement between the Corporation and the British Electric Traction Co. the Corporation can at any time call upon the company to carry out extensions, and if they decline to do so the Corporation may construct the lines. Cars now run to every part of the borough with the exception of Dewsbury Moor. There are acres of land in this district, and it is believed a tramway would encourage building operations and benefit the town financially, inasmuch as an increase in the rateable value would follow. A month or two ago the question was referred to a special tramways sub-committee, a suggestion being made at the same time that a service of motor 'buses might be introduced. The sub-committee have since gone into the subject, and they now recommend that the British Electric Traction Co. be requested to make a branch line from the bottom of Halifax-road up Williams-road, Moorhead-road, Boothroyd-lane, and Staincliffe-road to the borough boundary. If the company refuse to accede to the request, it is stated that the Corporation will seriously consider whether or not to make the line themselves. It is understood that the matter will come up for discussion at the next meeting of the Council. The company have asked the Council to accept one-fourth of the full rating assessment pending a test case contending that their undertaking is a "railway" within the meaning of the Act. The Council replied that the full rate must be paid, and they will hold the difference pending a decision.

Ramsgate.—The Board of Trade enquiry into the tramway accident at Ramsgate on Aug. 3 was opened at the Town Hall, Ramsgate, on Tuesday before Colonel von Donop. Stanley Frank Jones stated that he was conductor on the car. All went well until they reached the gardens at the Plains of Waterloo, Ramsgate. They stopped at the corner of Waterloo-crescent for seven passengers to get down; they did not take any on board. The witness then signalled to go on. As soon as they got on the slant it gradually got up speed. As it appeared to be going faster than it should do, the witness applied the slipper brake. The car was then at the end of the lawn, a little way before reaching Albion House. He remembered nothing further until they went over the cliff. The car flew by the usual stopping place. Replying to the inspector, the witness stated that he had been employed as a conductor for about six weeks before the accident. He had had no previous experience of tramway work. He had five or six days' training before he took charge of a car. On the loop line it was the duty of the conductor to put the slipper brake on before the car was restarted down the hill, and afterwards to ring to the driver to proceed. On the occasion referred to, he applied the slipper brake before reaching the stopping place. The car had appeared to be under proper control previously. There were six passengers in the car at the time of the accident. The manager of the tramway company testified that the track had been approved by the Board of Trade. Mr. A. E. Rossignol, consulting engineer, stated that he examined the car and the scene of the accident two days after. In his opinion, Madeira-walk was a dangerous road for tramway traffic, on account of the steep gradient and numerous curves, and it would be very difficult to prevent accidents from happening there. Just above where the accident happened the gradient was 1 in 13, and it was 1 in 16 where the car went off. He objected to the arrangement for dividing responsibility by giving the control of the slipper brake to the conductor. In his opinion, the slipper brake should be applied before the present Board of Trade stop was reached, and kept on. The superelevation needed correction, and the Board of Trade stops should be indicated by a special sign, so that there should be no slackness. The flanges of the wheels were in a rather dangerous condition, and ought to have been renewed earlier. He had found that the use of steel wheels with properly adjusted brakes was a great preventive of derailment. He further recommended that a special inspector should be appointed to supervise the men at all dangerous points. It would have been much better if a different route had been followed. He feared that there would always be a certain amount of danger on the present one. Cross-examined, the witness admitted that there were many more dangerous gradients in England. It is expected that the driver will not be in a fit condition to give evidence for two or three weeks, in consequence of which the inquiry was adjourned.

LIGHTING AND GENERAL.

Armagh Lunatic Asylum.—An expert is to be called in to examine all the electric lighting installation.

Acton.—Application is to be made for sanction to the borrowing of £225,000 for laying mains, etc., and other purposes of electric lighting.

Kashmir.—*Indian Engineering* says the Kashmir Durbar have accepted a scheme for developing electric power in the valley, but want funds.

Cleveland and South Durham Electric Power Co.—The Eston Urban District Council have approved the plans for the company's works at Grangetown.

Frinton-on-Sea (Essex).—We understand that the electric light and power station was destroyed by fire on Saturday. The damage is estimated at £3,000.

Brynmawr.—A further canvass of the town is to be made with regard to the proposed electric lighting, the councillors to be responsible for the canvass of their respective wards.

Buxton.—The report of the electrical engineer (Mr. Leeming) recommending that £4,000 should be expended in the extension of the works, has been adopted by the Urban District Council.

St. Marylebone.—The Borough Council's generating station at Lisson-grove is now so far advanced that the Council will soon be entirely independent of the Metropolitan Company's supply.

Standish.—The Lancashire Electric Power Co.'s main extends to Westhoughton. Before going any further the District Council propose to ask the Wigan Corporation for a price for current in bulk.

Grimsby.—The Electric Lighting Committee have agreed to a recommendation of a special sub-committee involving the expenditure of £18,000. The extensions include engines, dynamos, and mains.

Wells.—Strong representations are being made to the Postmaster-General on the question of telephonic communication, urging him to do all in his power to complete the installation in the city without delay.

Yorkshire Electric Power Co.—The Thornhill station has been started to supply Ravensthorpe, Mirfield, Liversedge, Birstall, Gomersal, Drighlington, Pudsey, and other districts within a radius of 15 miles from Thornhill.

Annfield Plain.—The Council are about to consider the question of what an electric plant of their own would cost, and whether they should enter upon the work of providing their own electric light for the whole of the district.

Rushall.—The accounts for the year show that the receipts from the telegraph station have been sufficient to cover the requirements of the Post Office and that the Council will not be required to make any payment under the guarantee.

Lowestoft.—The resident engineer's last report states that during the month 12 new consumers were connected with the mains, representing 338 8 c.p. lamps. There are now 639 consumers connected to the mains, representing 32,119 8-c.p. lamps.

Brighton.—Application is to be made for sanction to borrow £38,500 for works in connection with the electricity undertaking. The new connections during the past four years were 333, 489, 327, and 225 respectively, or an average of 344 connections per annum.

Ossett.—At the last Town Council meeting a resolution to the effect that the Council should proceed no further with the electric lighting scheme, but should apply for a further extension of time for putting the electric lighting order into force, was discussed and lost.

Bridgwater.—The Property Committee reported at the last Town Council meeting that an installation of electric light had been made to the chancel of St. Mary's Church, and the town clerk was directed to write the vicar and churchwardens thereon, and to give notice to the insurance company.

New Branch.—We are informed that the Sloan Electrical Co., 15, Fore-street-avenue, E.C., have, in consequence of the increase in the sale of "Conradty" carbons, opened offices and a warehouse at Manchester in order to promptly supply customers in the Midlands and the North of England.

Tenders Open.—Referring to an advertisement of Ashton-under-Lyne appearing in issue of Aug. 18, an error occurred as to the name of the gentleman to whom tenders were to be sent in. Corrected advertisement appears in our issue of to-day, from which it will be seen that tenders are to be sent in to Mr. Jno. Neal, borough comptroller.

Watford.—The electrical engineer reported at the last Urban District Council meeting that the number of consumers connected to date was 414. The Market-place sub-station has now been equipped and put into service. The Whippendell-road sub-station is now in use for public as well as private lighting supply. The revenue account for the year ended March 31 last is stated to be satisfactory.

Dissolution of Partnership.—As our readers are probably aware, Wm. Aug's Gibson Limited, now in liquidation, was a consolidation of interests of A. and P. Steven, of Glasgow, who have been established in the lift trade for nearly 60 years, and Mr. Wm. Aug's Gibson. Owing to some differences in opinion, the company has gone into liquidation under a special resolution. We are informed that Messrs. A. and P. Steven, having decided to do their business direct in future, have opened offices at Thanet House, 231-2, Strand, London, W.C.

Macclesfield.—The Green-street site has been adopted for the new electricity works, and the engineer (Mr. Woodward) is about to prepare plans and specifications for machinery required, and to advertise for tenders. Messrs. Whitaker and Bradburn have been appointed architects for the erection of the electricity supply works at a commission of 2½ per cent. on the erection of the building and 2½ per cent. on the specifications. The engineer has been instructed to advise the architects to have the advice of a chimney expert for the erection of a chimney 140ft. high, and to superintend the erection. Application is to be made for a loan of £16,000.

Pudsey.—The electric lighting will be commenced this week. The *Yorkshire Post* says that Messrs. William Lupton and Co., of Cliffe Mills, Pudsey, have already begun to use the current for power purposes, and before the week is out it will be used by several tradesmen for lighting purposes. During the Feast, which commences on Saturday, two 2,000-c.p. arc lamps will be placed at the entrance to the grounds. The current is purchased in bulk by the Corporation from the Yorkshire Electric Power Co., and in a station which has been erected by the Corporation it is transformed by the company from an alternating current of 10,000 volts to a continuous current of 500 volts. The whole of the compulsory area covered by the provisional order has been wired by the Corporation, some 3½ miles of cables having been laid.

Digitized by Google

Walsall.—The total number of consumers supplied on July 31 last was 423. During the past month the total units generated at the station were 114,709. The total output from the main generators was 110,793 units. The total units from the transformers were 85,214 (estimated). The total units registered on the meters were 82,635. The machinery was run for 702 hours. The wages paid amounted to £133.

Newport.—An inquiry has been held into an application of the Corporation for sanction to borrow £10,000 for the purposes of electric lighting and power—*i.e.*, £6,400 for mains and services for the supply of power, and £3,600 for meters. It is considered that this expenditure would cover the requirements for the next two years. It was stated that the demand was increasing. The total revenue last year was £24,149, and the gross profit £12,695.

North Wales Power Co.—The electric power station in course of erection in Cwm Dyli, at the head of Nant Gwynant, in which electrical current is to be generated by turbines driven with water from Llyn Llydaw, is nearly completed. The North Wales Power Co. are proceeding to erect overhead cables by way of Roman Bridge to Blaenau Festiniog, a distance of some eight miles, for the purpose of supplying current for power purposes to a number of quarries in the neighbourhood.

Handsworth.—The electricity supply mains have now all been laid and tested, and it is expected that the lighting will be commenced in about four weeks. The actual length of roads originally scheduled was 8,000 yards, but that figure has been doubled, and, in addition, the District Council have decided to lay a main to the boundary at Witton. There are 120 arc lamp standards, each of which carries also two incandescent lamps for use after midnight. The generating station is nearly finished. It is proposed to charge 1d. for each 8-c.p. lamp for about five hours' use. Churches and chapels will be supplied at a uniform rate of 4d. per unit. The total cost of the undertaking has been £45,000.

Wilmslow.—The Lord Mayor of Manchester last Monday opened an electrical exhibition, promoted by the Alderley and Wilmslow Electric Supply Co., in the Wilmslow Drill Hall. The exhibition was held to celebrate the inauguration of the supply of electricity in the urban district. The company's works were opened in October, 1899, and in the first month 372 8-c.p. lamps were connected in Alderley. At the beginning of the present year these had increased to 9 026, and a continued advance has been maintained. About 15 miles of distributors and feeders have been laid in Wilmslow, and all public lamps have been converted. The whole scheme has been carried out under the supervision of Mr. Cuthbert W. Bentley, the engineer and manager for the company. Part of the takings of the exhibition are to be handed over to the Wilmslow Charity and Sick Nursing Association.

London Gazette.—The partnership between John Joseph Jubb and George Kaye Spivey, carrying on business as electrical engineers at Batley Carr, Batley, has been dissolved by mutual consent. A receiving order has been made out on debtor's petition in the estate of Alfred John Earp, electrical and general engineer, 12, Palmerston-road, Boscombe, Bournemouth. The first meeting will be held at the Official Receiver's Office, Midland Bank-chambers, High-street, Southampton, on Aug. 30, at 3.15 p.m. A receiving order has been made out on creditors' petition in the estate of Albert John Harris, electrical engineer, and trading as A. J. Harris and Co. at Borough Mills, Bower-street, Bradford. The first meeting will be held at the Official Receiver's Chambers, 29, Tyrrel-street, Bradford. Nernst Electric Light Limited has been wound up voluntarily, and Mr. M. Levinger, manager and secretary of the company, appointed liquidator.

Greenock.—The engineer's report for June shows that the output for private supply and public lighting has increased 95 per cent. as compared with the corresponding month last year. For traction supply the increase was 26 per cent. The coal consumption has increased 60 per cent. because the condenser was not in use during the month on account of alterations. The output of electricity for the year ended June 30 last shows an increase of 60 per cent. for lighting and 14 per cent. for tramways. The income amounted to £16,336, of which £4,643 was received from the tramways. The expenditure totalled £8,204, leaving a gross surplus of £7,131, equal to about 7·5 per cent. on the capital prodided during the year. Allowing for the sinking fund at 3½ per cent. and 3 per cent. for interest, there remains a net surplus on the year's working of £1,593. The engineer estimates that the surplus next year will be £1,300. The sinking fund now stands at £13,000. Out of the extra 325,000 units sold last year, 106 000 (or 33 per cent.) have been used by installation fitted up by the Corporation owing to the popularity of the free wiring system. It is proposed to borrow £50,000 to cover the extensions required by the undertaking during the next five years. The cost of production is stated to be 1d. per unit.

Glasgow.—The Corporation have fixed the charges for the supply of electricity for the financial year June, 1905, to May, 1906, as follows: I. For lighting purposes (250-volt supply)—(1) Shops, warehouses, offices, theatres, halls and places of entertainment, and all other premises except those specified under heads 2 and 3, for any quantity of current equivalent to an average use of two hours per day (730 hours per annum) of the maximum demand as recorded upon the demand indicator, 3½d. per unit; for all current consumed over this quantity, 1d. per unit. (2) Domestic consumers, a uniform charge of 3½d. per unit. (3) Churches, a uniform charge of 3d. per unit. For stair-lighting purposes—for each 5 c.p. lamp lighted from sunset to sunrise, including cleaning, lighting, and extinguishing, 15s. per annum. II. For motive power purposes (250 and 500 volt supply)—(1) For any quantity of current up to an equivalent of 1,000 hours' use per annum of the maximum demand as recorded upon the demand indicator, 1½d. per unit; for all current consumed over this quantity, ¾d. per unit. (2) In cases where consumers can so arrange their demand that no current is taken during the hours between 5.30 and 6 p.m. in the months of November, December, and January, a uniform charge of 1d. per unit. The supply of current for motive power purposes is given subject to a minimum account of £2 per annum, payable in advance, but any account for current used by same consumer for lighting premises where power supply is given is to be set off against this minimum charge. The rates of charge for current for lighting shops, etc., and staircases, and the rates for motive power purposes, are substantial reductions on the rates charged last year, the maximum price for lighting being now 3½d. per unit as against 6d.

Pontardawe.—Mr. J. Morgan, consulting electrical engineer, has reported on a scheme for the electric lighting of the following parts of Pontardawe rural districts: Alltwen, Ynismeudwy, Trebanos, Clydach, Craigcefnparc, Ystalyfera, Brynamman, Gwauncaegurwen, Cwmgorse, Cwmllynfell, Rhos, Rhydyfro. The estimated aggregate requirement is 385 kw. It is suggested that a generating station be erected at Pontardawe, and Mr. Morgan considers that, owing to the large area that it is required to supply energy to, it will be necessary to generate at high tension. Except in the main streets, or where a large number of private consumers are close together, he advises overhead distribution, as being far cheaper in first cost, and because it can also be added to economically, besides saving the continual breaking of the streets. Two 16-c.p. incandescent lamps are to be fixed on the poles at distances varying from 60 to 100 yards. In Pontardawe underground cables are suggested for High and Herbert streets, where the old gas-lamp pillars can be utilised for the electric lamps. One hundred and sixty-four lamps will be required. Mr. Morgan recommends a surface condenser, if sufficient water can be obtained from the canal, as considerable steam consumption of engines will be reduced, as well as effecting a saving of 20 per cent. in fuel consumption. The total cost of the generating station is estimated at £9,260, the principal items being engines, generators, exciters, etc., amounting to £4,050; high-tension transmission lines, £7,200; low-tension distributors, £12,110; parliamentary expenses, £500; telephone system, £380; engineering expenses, £1 445; contingencies at £5 per cent., £1,545—a total of £32 440. Annual standing charges, £4,050; running expenses, etc., £1,829—total annual expenses, £5 880. The engineer suggests that a charge of £2. 10s. per lamp per annum be made; estimated revenue, £1,037. 10s.; from private consumers, £5,146. 17s. 6d. The total estimated revenue is £6,850, and the estimated expenditure £5,880.

Salford.—In his annual report Mr. C. D. Taite, electrical engineer, states that during last year there occurred no serious mishaps of any description, and that the economical results recorded in his last report have been more than maintained. The normal number of machines running on load in the winter evenings was five—three of these were used on the lighting and power supply up to 5.30 p.m., when one would usually be transferred to the tramway supply. The maximum load was 3,600 kw. Several small improvements in the boiler-house plant have reduced the cost of fuel per unit sold from ·22d. to ·19d., an improvement of nearly 14 per cent., but about 4 per cent. of this reduction is due to a more favourable coal contract. The coal consumption per unit sold has, however, been reduced from 5·26lb. in the previous year to 4·66lb. in the year under consideration. Mr. Taite says that the efforts of the staff in this direction have been greatly assisted by the diagrams obtained from the carbonic acid gas recorder, which indicate at once when the amount of air admitted to the furnaces is in excess of the requirements of the fuel; leakages of air through cracks in the brickwork are also shown up. In addition to fuel economies an arrangement has recently been introduced for cooling the coking bars of the mechanical stokers by means of a water service. These bars in the past have been the chief item of expenditure in connection with the upkeep of the stokers, and they have accounted for about half the total expense under this heading. The new arrangement is working most satisfactorily, and will be a notable economy. A further reduction in coal consumption may be expected during the current year, owing to improvements which are being carried out on the high-pressure valves. In consequence of the contract to supply the Manchester Ship Canal Company with electricity for use at the new No. 9 Dock it has been necessary to extend the lighting and power switchboard, and to instal a booster to furnish the necessary pressure. The switchboard has been built by the staff of the department, and is now ready for use; and a booster is being built by the British Westinghouse Company at Trafford Park. The batteries in the Frederick-road sub-station, after having been in use for about five years, are being renewed by the Tudor Accumulator Company. When completed, the available battery power will be equivalent to half the full-load power of one of the main engines. The report goes on as follows: During the year a considerable amount of work has been carried out at the old works to enable a portion of the buildings to be used as a central testing department for meters, motors, lamps, etc. The testing department was transferred from these premises to the new quarters at the end of last summer, and the additional space now provided enables the work of the department to be carried out in a more thorough and efficient manner than was possible previously. Incidentally, the room vacated at these offices by the removal of the department has permitted an important improvement to be effected here in the form of increased accommodation for the office staff. The mains department has been kept fairly busy throughout the year, owing largely to the work necessitated under the Prestwich provisional order. The length of the distributing mains has been increased by 6,918 yards. In addition to the above high-tension feeders have been laid up to a central point in Prestwich, where a sub-station is to be provided, and subsidiary feeders have been taken down several roads where the demand which is likely to arise does not warrant the laying of low-tension cables. A tramway feeder has also been laid for a distance of 2,400 yards from the borough boundary, and a further cable is to be installed for the tramway system in Bury Old-road, Prestwich. The whole of the feeder and distributing system throughout the borough and outlying districts has been kept in excellent order by means of

Digitized by Google

systematic testing, and the low-tension system has been entirely free from serious faults; 183 new consumers have been obtained, and the new connections are equivalent to 16,112 8-c.p. lamps and 815 h.p. in motors. During the present year the supply to the Manchester Ship Canal will be inaugurated and that to the Broughton Copper Company largely increased, and as a result the motor connections will experience a very marked expansion. The motor hiring business has made steady progress, there being, at March 31, 165 motors on hire of an aggregate of 1,367 h.p., compared with 105 motors of 954 h.p. 12 months previously. As the price of current for power purposes is to be reduced from July 1 a still more rapid expansion of this department is not unlikely. The net profit for the past year amounted to the sum of £7,514, which has been allocated as follows: depreciation and reserve, £3,000; contribution in reduction of rates, £4,514. The amount set aside for depreciation and reserve represents only a fraction over half of 1 per cent. on the capital expenditure at the end of the year, and, having regard to the possibility of obsolescence and the high capital expenditure per kilowatt of plant installed, this sum cannot be considered an adequate provision for future contingencies; further, for the current year, out of an anticipated profit of £10,650, no less than £7,500 has to be contributed in aid of the rates, leaving only £3,150 for depreciation and reserve, a quite inadequate amount. The gross profit for the year was £40,696, equivalent to 7½ per cent. on the capital invested at the end of the year; this compares with a gross profit of £42,860 last year, equivalent to 8 per cent. on the then capital. The diminution in the gross and net profits is entirely due to the reduction made in the price of current, not only to the tramway department, but also to ordinary consumers; thus the price charged to the former was 1·5d. in place of 1·95d. per unit, while the average price to ordinary consumers came down from 2·56d. to 2·17d. per unit sold. The gross profit has been dealt with as follows: interest on loans, £16,455; sinking fund, £16,727; net profit, £7,514. The total sum which has been paid to the sinking fund since the commencement of the undertaking now amounts to £64,726. The depreciation and reserve fund stands at £11,000. Compared with the previous year there has been an increased sale of over 1½ million units, while the total cost of production has been reduced just over ½d. per unit sold. All the items of expenditure show a reduction per unit sold with the exception of management, under which heading are included several special items which will not occur again—*e.g.*, the cost of the Prestwich electric lighting provisional order. The works costs have been reduced below ½d. per unit, and the figure of ·19d. for coal is the lowest yet published by any municipal undertaking. The capital expenditure during the year has been less than for any year since 1898; a large proportion of the expenditure is due to the extension of mains, while motors on hire come next with an outlay of £2,170. The sum included under the heading of buildings is due to the payment of the balance of the architect's fees. During the present year the expenditure is again likely to be small. A comparison between the cost of the Salford undertaking and those of other towns shows that as a result of the improved figures obtained Salford now takes precedence over Bradford, and ties with Newcastle-on-Tyne Co. for third place amongst over 240 undertakings. As regards municipal undertakings, Rotherham is the only one which has obtained results better than Salford. In conclusion, Mr. Taite testifies to the splendid assistance given him by the staff of the department.

PROVISIONAL PATENTS, 1905.

AUG. 14.

16457. An improved bayonet socket-holder for incandescent electric lamps. James Cleary, 119, Waldegrave-road, Preston Park, Brighton.

16460. An automatic starter for electromotors. Johannes Jessen, Zürich-Langnau, Switzerland. (Complete specification.)

16471. Improvements in lamps for Nernst filaments. Leo Kamm, 27, Powell-street, Goswell-road, London.

16479. Improvements in and relating to telephone systems. Jacob William Lattig and Charles Lane Goodrum, 77, Chancery-lane, London. (Complete specification.)

16484. Improvements in call signal apparatus for group-calling in telephone installations. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Akt.-Ges., Germany.) (Complete specification.)

16491. Coiling apparatus for hollow or solid flexible conductors for gas, electricity, and the like with auxiliary support for the hollow conductors. Samuel Quincey and Charles Harrison, 136, Kentish Town-road, London.

16518. Improvements in dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.) (Complete specification.)

AUG. 15.

16545. Improvements in or relating to electric arc lamps. Adrian Denman Jones and the Jandus Arc Lamp and Electric Company, Limited, Hartham Works, Hartham-road, Holloway, London.

16546. Improvements in or relating to electric arc lamps. Adrian Denman Jones and the Jandus Arc Lamp and Electric Company, Limited, Hartham Works, Hartham-road, Holloway, London.

16547. Improvements in or relating to electric arc lamps. Bernard Mervyn Drake, Adrian Denman Jones, and the Jandus Arc Lamp and Electric Company, Limited, Hartham Works, Hartham-road, Holloway, London.

16570. Improvements in storage batteries. Gustave K. Hartung, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

16571. An improved attachment device for the shades of inverted incandescent gas and electric fittings. Entwistle and Stephens, Limited, and Henry Edward Dane, 8, Quality-court, Chancery-lane, London.

16587. Improvements in lightning arresters or like protective devices. Isidore Bernard Birnbaum, 322, High Holborn, London. (Joseph Nübel, Germany.)

AUG. 16.

16621. Improvements in electric terminal fittings for making connection between the various main and branch cables in conduit junction boxes. Charles Edward Gunner, Embank, Kemble-road, Waldon, Surrey.

16631. Improvements in the manufacture of electrical resistances. Charles Rozicka, Clun House, Surrey-street, London.

16655. Improvements in or relating to wireless telegraphy. Guglielmo Marconi and Marconi's Wireless Telegraph Company, Limited, 24, Southampton-buildings, Chancery-lane, London.

16656. Improvements in tremblers for electric sparking apparatus. Marconi's Wireless Telegraph Company, Limited, and Edward Priddle, 24, Southampton-buildings, Chancery-lane, London.

16657. Improvements in and relating to electric arc lamps. The British Thomson-Houston Company, Limited, and Edwin Joseph Murphy, 83, Cannon-street, London.

AUG. 17.

13964A. Improvements in and connected with electric lighting or other installations. Percy Fullerton Corkhill, 6, Lord-street, Liverpool. (Date applied for under Rule 5 of the Patents Rules 1905, July 6, 1905.) (Complete specification.)

16664. Electrical and automatic means for indicating the number of occupied seats on or in a tramcar, omnibus, or other vehicle, place of amusement, or the like, and means for indicating the position of such seats. Benjamin Lewin Moseley, 147, Mackenzie-road, Beckenham, Kent.

16671. Electric working of mine shafts. James Swinburne, 82, Victoria-street, Westminster, London.

AUG. 18.

16772. Improvements in and relating to connection boxes for electric cranes. Siemens Bros. and Co., Limited, and Johnson Snow Huddleston, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

16773. Improvements in revolving field magnets for electrical machines. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens-Schuckertwerke, G. m. b. H., Germany.) (Complete specification.)

16796. Improvements in devices for the electrographical long-distance transmission and reception of drawings photographs, and the like. Henri Carbonnelle, 322, High Holborn, London. (Complete specification.)

AUG. 19.

16821. Improvements in and connected with apparatus for cooling water for condensing and other purposes. James Henry Brown, 4, Corporation-street, Manchester. (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

NOTES.

Municipal Ownership.—Municipal enterprise has entered many fields of late years, but probably in no other place does it take a more diversified form than in Freiburg, Germany, which must rival Glasgow in this respect. Besides electric cars, lighting, and power, the local authorities deal in a theatre, restaurant, savings bank, pawnshop, farms, workmen's cottages, an undertaker's business, and sundry details. One is inclined to wonder what the inhabitants do.

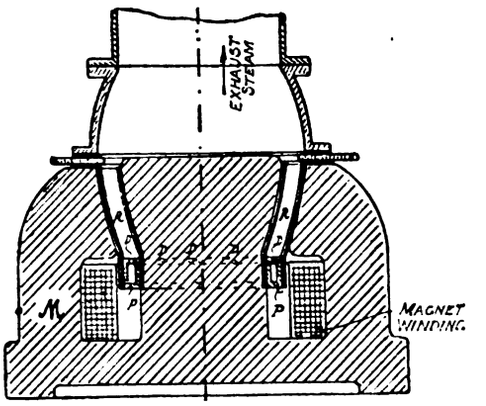
Telephony to the Continent.—Commencing to-day, the subscribers of the National Telephone Company will be enabled to use the Anglo-French and Anglo-Belgian telephone services on the same conditions as Post Office subscribers. It has been found necessary to limit the scope of operations in the first instance to the company's exchanges in London and the chief exchange in each provincial town where Post Office subscribers are at present admitted to the through service.

The South Wales Coalfield.—A detailed map on a large scale has been prepared by Mr. G. E. Gordon, mining engineer, of Swansea, showing the collieries, works, etc., in the South Wales coalfield. Besides giving full particulars under these heads, the map indicates the railways and stations, canals, and the class of coal obtained. There are also diagrams showing the average prices of the last decade and the annual output since 1860. The work, which is admirably executed, shows the various centres clearly, and should be of decided value to engineers for reference. Incidentally, the numerous dots illustrative of the mines and works exemplify what an extensive and, at the same time, compact area the South Wales Power Company have to work upon for the supply of energy for industrial purposes.

Trade Marks.—The new Trade Marks Act, which will come into operation on April 1, seems likely to place this branch of legislation on a more satisfactory footing. The following definition has been drafted with a view to giving a wider range in the selection of trade marks: "It shall mean a mark used or proposed to be used upon or in connection with goods for the purpose of indicating that they are the goods of the proprietor of such trade mark by virtue of manufacture, selection, certification, dealing with, or offering for sale." A company will now, for the first time, be allowed to register its name if represented in a special or particular manner, these words being substituted for "particular and distinctive manner" in the existing Act. An important provision is made in Section 62, which enables associations to register special trade marks to be used by the various members of such associations for the purpose of guaranteeing a standard or mode of manufacture of particular goods. The registration of associated trade marks is another useful provision, enabling an applicant to register the essential features of a label as separate trade marks. Section 41 enacts that registration shall after seven years be taken to be valid in all respects, unless obtained by fraud or calculated to deceive.

Electricity for Mining Marble.—One of the latest uses of electricity is for the mining of marble. This method has come much into favour in America, and it is estimated that in the State of Vermont alone the greater part of a million pounds has already been invested in electrical machinery and equipment for the quarries. While the marble industry was of moderate extent, steam derricks, drills, and locomotives answered the purpose, but the business rapidly assumed such dimensions as to render a change of method necessary, and electric power was introduced. This was found to be particularly valuable for operating large cranes, greater efficiency and economy resulting. It has only been within the last year or two that electric channelling machines have been used, but they have given so much satisfaction that their use is steadily increasing. The electrically-operated machine cuts on either side of it a channel from 4ft. to 10ft. deep and less than 2in. wide, whereas the steam type of channelling machine cut but one channel at a time. A single electric motor mounted on the machine and travelling with it operates the cutting implements, and also drives the traction gear of the machine. In addition, electrically-operated chisels, sand saws, buffers, and other devices are employed.

A New Unipolar Dynamo.—A German patent (No. 156,029) has been issued to Mr. A. Beringer for a unipolar dynamo of the type indicated in the accompanying diagram. An annular channel, R, with insulation



sides and situated between the circular poles of a magnet, M, contains a conducting fluid which is set in rapid motion by the direct impact of steam through a set of nozzles. In contact with the top and bottom of this rotating fluid are two electrodes, which serve to deliver the current generated into the outer circuit.

Submarine Signalling.—A further trial of submarine signalling by the Trinity House was made last week between the Trinity yacht "Irene" and the North Goodwin lightship. A reference to the previous trial appeared in our issue of Aug. 18. The "Irene" steamed out to the lightship so that the signal bell might be heard at close quarters and then retired, manœuvring at the same time in order to bring the lightship first on the one side and then on the other to test the hearing of the signal at various distances and positions. The bell could be distinctly heard over a distance of more than four miles. A notable phenomenon was observed on this occasion. At a distance of over two miles the submarine bell could be distinctly heard without the aid of the transmitters and the telephone by merely placing the ear against the wood casing at the side of the ship below or to one of the stanchions on deck. Altogether, the proceedings were regarded as having fully maintained the claim of the system to be a practical aid to navigation, and the representatives of various cross-Channel services expressed a favourable opinion of its possibilities. Arrangements have just been made by the managers of the White Star Line to have the apparatus fitted in the "Oceanic" and "Baltic," and the Holland-America Line have also announced their intention of adopting it.

Electrical Units and Standards.—As stated last week, the Elektrotechnische Reichsanstalt has called a conference, preparatory to the meeting of the International Commission of Electrical Units and Standards. This course is to be highly commended, and is in accord with the recommendations of the St. Louis International Electrical Congress, which advocated that the differences

Digitized by Google

in the laws of various countries in reference to electrical units should be considered by an international commission. This conference is expected to be held at the end of next month, and invitations have been sent to the Governments of Great Britain, the United States, France, Austro-Hungary, and Belgium. The object to be aimed at by such a body is that the units of the different countries should harmonise within commercial limits rather than that ideal theoretical definitions should be laid down. The present United States volt, for example, is about ·1 per cent. less than that which is standard in some countries, and although this is a negligible quantity in many operations it becomes appreciable when dealing with, for instance, incandescent lamps. With the modern attainments of electrical science it should be possible to fix an international unit to within ·04 or even ·02 per cent. The movement is an eminently desirable one, and we trust that it will prove successful.

East London College.—We have received a copy of the prospectus of this foundation for the Michaelmas term, which commences on the 18th inst. for day pupils and the 25th inst. for evening students. In addition to affording a good general education there are courses in science and technical subjects, including electrical engineering. To these the governors have decided to add an arts section, so that the college may more completely fulfil its function as the University College for East London. In regard to the general scheme of education, a preparatory class, designed to meet the requirement of the London matriculation examination, has been formed to meet the needs of boys between the ages of 15 and 16 who have passed through a course of instruction in a secondary day school, but are not sufficiently advanced to take any of the prescribed college courses. Boys will not be retained in this class after 17 years of age. In July next the Drapers' Company will award four scholarships tenable at the college for boys belonging to certain foundation schools, nine scholarships (six for males and three for females between 16 and 19 years of age) to be judged on the result of the London inter-collegiate scholarship science examination on Oct. 1, 1906, and six scholarships (three for males and three for females) to be judged on the result of the corresponding art examination. The general technological scheme of the foundation shows an excellent standard, and promises to be of great assistance to students in the area covered by the college. The electrical engineering department comprises an excellent set of laboratories and workshops, and students are taken through a three-year course.

Colonisation.—The address of the Rev. W. Cunningham, president of the Economic Science and Statistics Section, to that branch of the British Association dealt with "Unconscious Assumptions in Economics." After a general survey of economic history and conditions, the president discussed the possibilities of mining in the development of countries, and gave some excellent reasons for dissenting from the view that mining could never form a stable foundation for the building up of a community, although this was the opinion of such eminent authorities as Bacon and Adam Smith. He remarked that it would be wise to discriminate a little before adopting this conclusion, and to examine the condition of, for example, different parts of Spanish America separately. The richest mines of all—those of Peru—were situated on the arid slopes of the Andes, where cultivation was impossible, and there were insuperable obstacles to the planting of well-ordered and prosperous communities; but very different results were achieved in Mexico. These workings occurred on a plateau where cultivation and settlement were possible, and the wealth which was obtained by mining reacted on the prosperity both of agriculture and manufactures. Extractive industry served to give a stimulus to that varied life, partly urban and partly rural, which is necessary for a community that hopes to take a real and independent place in the civilised activities of the world. It was foolish to jump to the conclusion either that mining gives a feverish and unhealthy stimulus, or that the Spanish system of regulation was incurably bad; we ought to distinguish carefully, and to try to learn from Spanish experience, both in South and in Central America, what were the conditions under which mining for the precious metals could be pursued so as to be not merely of temporary but of permanent advantage to the welfare of the community.

Electricity versus Steam.—In the course of his address to the Richmond (U.S.A.) Railroad Club, Mr. A. H. Armstrong, of the General Electric Company, gave some interesting figures relative to steam and electricity as the motive power for railroads. The electric locomotives which the General Electric Company are constructing for the New York Central line to Mothaven are not designed to effect any considerable increase in the present schedule for steam trains, except that acceleration to neutralise the stoppage for changing from steam to electricity at the section is to be provided for. It is found, however, that the electric locomotives will develop at the rim of the drivers some 3,000 h.p., or more than double the indicated horse-power of the largest steam locomotive on the line. It is also calculated that the weight of the electric locomotive would not exceed 200,000lb., against 250,000lb. for the typical steam locomotive. Mr. Armstrong gave a specific instance of the delusive tests sometimes advanced by steam railway engineers. On a railroad in a Western State there is a 20-mile section where the grade causes the cost of fuel to aggregate about 70 per cent. of the entire operating expenses, besides which the locomotive repairs represent over £1,000 a year, or a third of the cost of the locomotive. The figure for fuel given by the railroad engineer to an investigating electrical engineer was 10 per cent. only of the entire operating expenses, this amount representing not the cost on the actual section but the average cost on the whole system. After further investigation the electrical engineer found that, by utilising the available water power for electrification of the section, a saving could be effected sufficient to pay 15 per cent. on the investment, even with a service of only six trains a day. Further examples were given by Mr. Armstrong to show that, apart from water power, there were many lines where electricity could be used with advantage.

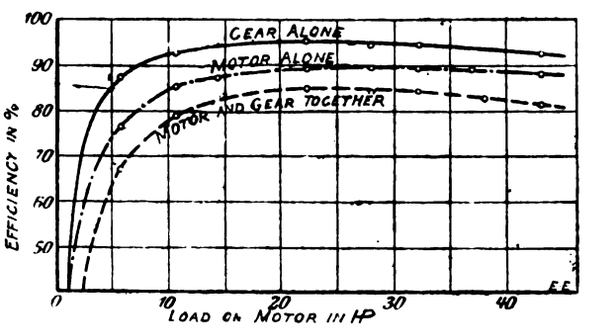
Patents.—We referred in our issue of March 31 to a memorial subscribed to by a number of eminent engineering and scientific signatories, and also by some 40 patent agents, urging a modification of No. 10 of the patent regulations which came into force on Jan. 1. The petitioners expressed the opinion that the Act of 1902 was designed to afford, both to the inventor and the public, the benefit of an official examination as to novelty without incurring the serious risk of inflicting injury upon the inventor by refusing a patent for alleged want of novelty, or by making public adverse official opinions. As framed, however, Rule 10 appears to be based upon the assumption that the Patent Office is charged with the function of publishing an official opinion to the world by placing an endorsement upon the specification whenever it appears to the examiner or controller that no patentable invention is disclosed, instead of merely requiring the applicant to mention any prior specification, a knowledge of which might be deemed necessary to enable the public to form an accurate opinion

Digitized by Google

as to the validity of the patent. As we remarked in our previous reference to the subject, the oppressiveness of the regulation is accentuated by the fact that an examiner, or even the comptroller, while acting with the best possible intentions, might easily err in construing an invention as an anticipation when experts have disagreed upon similar points. It may be mentioned that a counter memorial was presented by 76 registered patent agents. The Board of Trade, in communicating their decision, intimate that, after consultation with the law officers, they see no occasion to alter the rule. The stringency of the regulation may conceivably be to the public interest in some cases, but its general tendency, we should say, is in the opposite direction. A well-established holder of a patent could hold it over the heads of others, and virtually coerce them into selling him their grants on terms favourable to him, with the alternative of paying him a royalty. Taken altogether, it is to be hoped that additional experience of the operation of this rule will induce the authorities to reconsider their decision.

Engineering in South Africa.—The address to the Engineering Section of the British Association by Sir Colin Scott Moncrieff, the president, dealt chiefly with the subject of irrigation. Tracing the methods from their primitive origin to modern practice, he dealt with pumps, windmills and artesian wells, but we are rather disappointed to find that he made no allusion to electricity, which has been employed for irrigation in certain parts of the world, including California, one of the places dealt with by Sir Colin. Pumps worked by steam power are extensively used by cotton growers on the banks of the Nile. Where wind can be relied on, the windmill is a very useful and cheap means of raising water. But everything depends on the force and reliability of the wind. In the dry Western States of America, wind power is largely used for pumping. Wind is of little use if its velocity is less than six miles an hour, but it can be utilised to a considerable extent in the regions just mentioned, where the average velocity is eight miles an hour. As, however, windmills should discharge their water into a tank, irrigation cannot go on without cessation day and night, and the mill may be pumping its best when irrigation is least needed. In America it is found that pumping by wind power costs about two-thirds that of steam power. With a reservoir, five to fifteen acres may be kept irrigated by a windmill; without a reservoir, three acres is as much as can be depended upon. Windmills attached to wells from 30ft. to 150ft. deep cost from £30 to £70. The windmill has done useful work in this field, but its area is limited, and much less than that promised by electricity, which may be expected to come in for more attention in the future. Speaking of artesian wells, Sir Colin said that so far they had not proved of great value for irrigation. In the State of California there are reported to be 8,097 artesian wells, of a mean depth of 210ft., discharge ·12 cubic feet per second, the cost on an average being £50. Thirteen acres per well is accounted a large output. The speaker remarked that where water had to be raised on to the field there was an outlay of human or mechanical power that might be saved if the water could be brought to flow over the fields by gravitation. Where this is not possible electrical transmission of energy for pumping purposes may reclaim many districts.

Worm-Geared Traction Motors.—The Maschinen Fabrik Oerlikon has recently repeated the experiment of employing worm gear with traction motors. Earlier experiments in this direction proved unsatisfactory, principally because the worm gearing available at that time was not sufficiently well made to give a high efficiency, and also because, with the rigid connection between motor and gear which was employed, the shocks and consequent wear proved excessive. These difficulties have been largely overcome in the recent construction, and an experimental car containing two 20-h.p., 1,200-revolution, worm-geared motors gave very satisfactory results. The motors only weighed 675lb., in place of 1,460lb. each, which would have been the case if ordinary single-reduction spur gear and 500-revolution motors had been used. The gear ratio was 12 : 1, the worm being of hard steel, with a triple thread having a pitch diameter of 3in. and a pitch of ·45in., whilst the worm wheel had a cast-iron hub with phosphor-bronze toothed rim attached, a pitch diameter of 18·3in. and 36 teeth. The motors were rigidly fixed to the car frame in accessible positions, and were connected to the worms through double flexible couplings, which allowed the necessary freedom of motion for the car springs. The worms and worm wheels are arranged on the outside of the car wheels, and run completely enclosed in oil baths. The end thrust is taken up on ball bearings. The gear was found to have an efficiency exceeding 90 per cent. for all loads between one-fifth load and full load, as is shown by the curves in the



accompanying diagram, which we reproduce from the *Elektrotechnische Zeitschrift*. The wear and the cost of upkeep proved to be less than with the ordinary spur gear, and the running was practically noiseless and free from shocks.

New Publications.—The *Proceedings* of the American Institute of Electrical Engineers, dated August, contain the discussions on "Measuring Instruments," "Time-Limit Relays," and "Duplication of Electrical Apparatus to Secure Reliability of Service." There is also a paper by Mr. C. E. Waddell, entitled "The Preservation of the Southern Appalachian Streams: A Forest Problem."—The *Bulletin* of the Imperial Institute contains reports upon a number of commercial matters, including rocks and minerals from the British Central Africa Protectorate, rubber in the East Africa Protectorate and Madras, the occurrences and uses of minerals containing thorium, and the utilisation of peat.—Messrs. P. S. King and Son have issued at the price of 1s. a report embodying "A Comparison of the Brassworkers of Berlin and of Birmingham,' compiled by Messrs. R. H. Best, W. J. Davis, and C. Perks. The object of the authors' investigations was to ascertain whether the brassworkers of Berlin "have succeeded in attaining a more desirable physical and industrial life than that led by the brassworkers of Birmingham." Their lengthy tour of inspection has highly impressed the authors with the sanitary condition of the German capital, and there are chapters dealing specifically with "The Education of the Child of the Brassworker"; "The Temperance Question"; "Trade Conditions"; "National Compulsory Insurance: Sickness, Old Age, and Infirmity"; and "Institutions." The authors, without pronouncing a positive decision, obviously consider that Berlin does not suffer by the comparison. The publication affords an interesting study of the sociological and

Digitized by Google

economic conditions prevailing in one of the most important metal industries.—In response to numerous applications for copies of his paper on "Lightning Conductors," read before the Birmingham Electric Club and other institutions, Mr. W. H. Whitehouse, of 37A, Waterloo-street, Birmingham, has had an edition of the paper printed. It contains a highly interesting review of the evolution of the lightning conductor upon the usually accepted lines, leaving it for Sir Oliver Lodge and the Lightning Research Committee to introduce new phases.—We have received from Messrs. Archibald Constable and Co. volumes 2 and 3 (price 6s. each) of "National Engineering and Trade Lectures," edited by Mr. B. H. Morgan. In No. 2 Mr. P. R. Björling deals with "British Progress in Pumps and Pumping Engines," while in volume 3 Mr. C. E. Brackenbury treats of "British Progress in Gasworks' Plant and Machinery."

Iron and Steel Institute—The arrangements have been practically completed for the Sheffield meeting, which is to be held on the 26th, 27th, 28th, and 29th inst. The following is a revised list of the papers that have been offered: "The Wear of Steel Rails on Bridges," by Mr. T. Andrews, F.R.S.; "The Metallurgical Department of Sheffield University," by Prof. J. O. Arnold; "The Thermal Transformation of Carbon Steels," by Prof. J. O. Arnold and Mr. A. McWilliam: "The Nature of Troostite," by Dr. Carl Benedicks; "The Occurrence of Copper, Cobalt, and Nickel in American Pig Irons," by Prof. E. D. Campbell; "The Transformations of Nickel Steels," by M. L. Dumas; "Steel for Motorcar Construction, and on Vanadium Steels," by M. L. Guillet; "The Presence of Greenish-Coloured Markings in the Fractured Surface of Test-Pieces," by Capt. H. G. Howorth, R.A.; "Overheated Steel," by Messrs. A. W. Richards and J. E. Stead, F.R.S.; "Segregation in Steel Ingots," by Mr. B. Talbot; "A Manipulator for Steel Bars," by Mr. Douglas Upton; and "The Influence of Carbon on Nickel and Iron," by Mr. G. B. Waterhouse. Members who intend to take part in the discussion will, on notifying such intention to the secretary (Mr. Bennett H. Brough), have copies of the papers forwarded to them a week in advance, as far as that may be possible. The Housing Committee of the Sheffield Reception Committee are making arrangements for the accommodation of members, but it has been found necessary to limit the invitations to the fair sex, and hospitality cannot therefore be extended to more than one lady per member. The chairman of the executive committee is Colonel H. Hughes, C.M.G., and Mr. F. Huntsman is hon. treasurer; Mr. J. Rossiter Hoyle, vice-chairman; and Prof. J. O. Arnold, Mr. A. McWilliam, and Mr. John Wortley, hon. secretaries. The hon. secretaries' office for the registration of addresses, issue of badges of membership, programmes, invitation cards, etc., will be in the Cutlers' Hall, Sheffield, where arrangements will be made for the dispatch of letters and telegrams (telegraphic address: Irosamente, Sheffield), and for the use of the telephone. To the list of firms who will be pleased to receive members desiring to see their works the name of Messrs. Davy Bros., Limited, engineers, Sheffield, should be added. By the courtesy of the committees of the Sheffield Club, of the Sheffield Conservative and Unionist Club, and of the Sheffield Reform Club, the privileges of honorary membership will be extended to members during the meeting. Those desirous of availing themselves of this kindness are requested to intimate to the secretary of the institute to which of the clubs they would prefer to be elected. By the courtesy of the Great Western, the Midland, the Caledonian, the London and North-Western, the Great Northern, the Lancashire and Yorkshire, the Great Central, and other railway companies, return tickets to Sheffield at a single fare and a quarter, available from Sept. 23 to Sept. 30, will be issued from London and provincial towns on production of a voucher signed by the secretary, which will be forwarded on application.

Mathematics in Science. — The address delivered by Prof. A. R Forsyth, president of the section, to the mathematical and physical branch of the British Association comprised an extremely interesting review of the history of mathematics in relation to science. He alluded to the work of Bacon, Descartes, Copernicus, Galileo, Halley, Leibnitz, Kepler, Newton, Stokes, Maxwell, and others, and after tracing the development of astronomical science, he referred to the progress of physics, which, alike on the mathematical and the experimental side, had been no less remarkable or unrestricted. The elaborate and occasionally fantastic theories of the eighteenth century in such subjects as light, heat, even as to matter itself, were rejected in favour of simpler and more comprehensive theories. There was one stage when it seemed as if the mathematical physicists were gradually overtaking the experimental physicists; but the discoveries in electricity begun by Faraday left the mathematicians far behind. Much had been done towards the old duty, ever insistent, of explaining new phenomena, and the names of Maxwell, Weber, Neumann, and Hertz need only to be mentioned in order to suggest the progress that has been made in one subject alone. "We need not hesitate," he proceeded, "to let our thoughts couple, with the great physicists of the century, the leaders of that brilliant band of workers upon the properties of matter who carry us on from wonder to wonder with the passage of each successive year." Further, it had been an age when technical applications have marched at a marvellous pace. So great had been their growth that we were apt to forget their comparative youth; yet it was only the middle of the century which saw the awakening from what now might be regarded as the dark ages. Nor was the field of possible application nearing exhaustion: on the contrary, it seemed to be increasing by reason of new discoveries in pure science that yet will find some beneficent outcome in practice. Invisible rays and wireless telegraphy might be cited as instances that were occupying present activities, not to speak of radium, the unfolding of whose future was watched by eager minds. One gap in this subject struck the professor. There were great histories of mathematics and great histories of astronomy, but he could find no history of physics on the grand scale. Some serviceable manuals there are, as well as monographs on particular topics; what seemed to him to be lacking was some comprehensive and comparative survey of the whole range. The history of any of the natural sciences, like the history of human activity, is not merely an encyclopædic record of past facts; it reveals both the spirit and the wealth which the past has bequeathed to the present, and which, in due course, the present will influence before transmission to the future. Perhaps all our physicists were too busy to spare the labour needed for the production of a comprehensive history, yet he could not help thinking that such a contribution to the subject would be of great value, not to physicists alone. Dealing with the inter-relation between mathematical physics and pure mathematics, the professor stated that they had given much to each other in the past, and would do so in the future, in doing which they would take harmonised action in furthering the progress of knowledge.

Artom's Method of Wireless Signals.—Acting on a suggestion, made by Prof. Righi in the course of a

Digitized by Google

mathematical investigation, that two rectangular sets of electrical waves of the same amplitude, frequency, and with a phase displacement of one-quarter wave-length, would set up circularly-polarised vibrations, Prof. Artom decided to attempt the practical application of such an arrangement to wireless telegraphy purposes. If the theoretical requirements are completely fulfilled, the circularly-polarised waves will be set up in a given direction, this direction being at right angles to the centre of the plane in which the oscillations occur. The method employed for producing the two fundamental sets of waves is the same as that commonly employed for producing rotating magnetic fields. Thus, in Fig. 1, by suitably proportioning the self-inductions, resistances, and capacity, the currents in the two branches, M N and

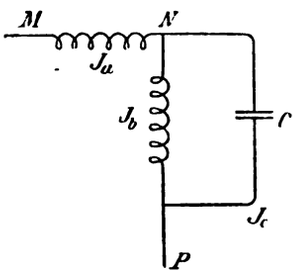


FIG. 1.

N P, can be made equal ($J_a = J_b$) but different in phase by $\frac{\pi}{2}$. If the voltage difference between N and P be V, and V is represented by the line O V in Fig. 2, the current J_c will be represented by the line O J_c at right angles to O V and equal to $2\pi n$ C V. If r_2 is the ohmic resistance and L_2 the self-induction of N P, the value of J_b is $\frac{V}{\sqrt{r_2^2 + 4\pi^2 n^2 L_2^2}}$. J_b will have a phase angle relatively to O V of such a value that the tangent of the angle $= \frac{2\pi n L_2}{r_2}$. When $2\pi n L_2$ is made equal to r_2 this angle is 45deg., and, as is seen in Fig. 2, the current J_a, which is the resultant of J_b and J_c, is equal to J_b, and is at an angle of 90deg. to the latter, provided that J_c is given the value $2 J_b \cos 45\text{deg}$. This value is attained when $4\pi^2 n^2 L_2 C = 1$—*i e*, when the circuits are in resonance. When these conditions are fulfilled, the currents J_a and J_b will produce a rotating field. Prof. Artom arranged the three ends,

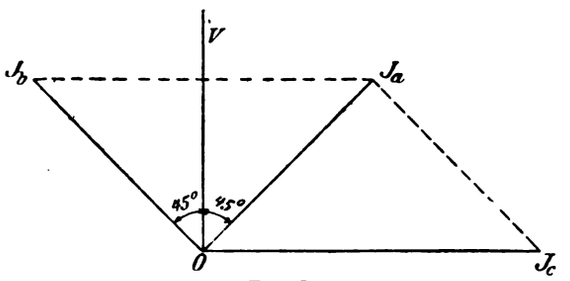

FIG. 2.

M, N, and P, of the circuit at the corner of a right-angle triangle with two equal sides (Fig. 3), and by selecting the proper values for the self-induction, S, and the capacity, C, obtained equal discharges between N and P and between N and M, with a phase difference of 90deg. The effect of the magnetic rotating field was practically dissipated by the excessive hysteresis losses which occurred at the high frequencies employed, but the electrical rotating field was readily observed. Thus, light glass shades supported on fine glass points were set in rotation when placed six or seven inches from the oscillator (supplied with 80 volts 5 amperes). When the connections were changed so that M N in place of P N formed part of the resonant circuit, the rotation of the glass shade was reversed. In order to avoid the disturbing effects of leakage at the spark gap, air wires were employed later. These air wires or antennæ consisted of single wires, but better still are systems of wires, of exactly equal length, connected direct to the spheres M and P, and set at right angles to one another, as in Fig. 4. In this way two equal sets of waves are sent out with a phase displacement of one-quarter wave-length, combining to produce circularly-polarised electromagnetic wires advancing along an axis set

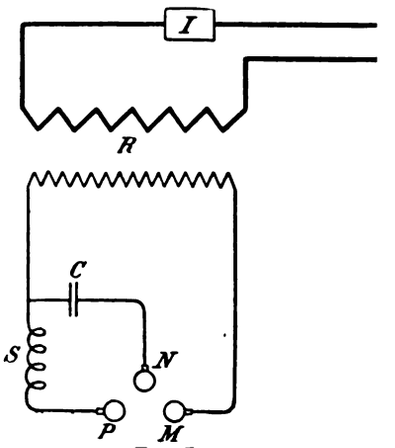

FIG. 3.

at the centre of the cross-point of the wires and at right angles to their plane. In place of a phase displacement of $\frac{\pi}{2}$, it is possible to obtain a rotating field and circularly-polarised waves with any other phase relation ϕ between two sets of waves of equal amplitude, provided that the antennæ are crossed at an angle of $(\pi - \phi)$. In conclusion, Prof. Artom gives particulars of some interesting practical tests carried out in the years 1903-4 in connection with the Italian navy. When signalling between S. Vito and S. Bartolomeo, in the Gulf of Spezzia, over a distance of 2½ miles, the stations at Varignano and Palmaria, lying a few miles out of the direct line, were quite unaffected. Signalling between Rome and Anzio (38 miles) clear records were obtained so

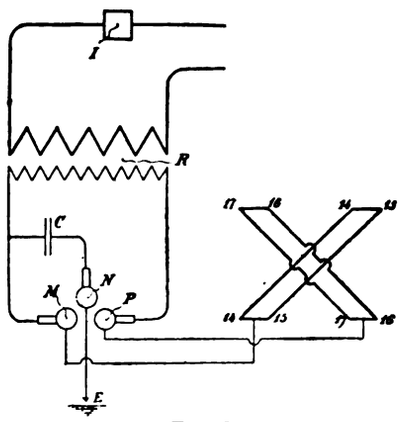

FIG. 4.

long as the axis was correctly directed, but ceased as soon as the radiator was directed on Sardinia. When signalling from Rome over 75 miles to the island of Ponza, the energy required to transmit readable signals could be trebled without making it possible to obtain records on the island of Maddalena (to the north of Sardinia), whilst when signalling between Rome and Maddalena (165 miles) no signals could be obtained at Ponza. When sufficient energy for 180 miles in the direction Rome-Maddalena was applied, signals could only be obtained for a distance of 60 miles in the direction Rome-Ponza. Shorter antennæ were also found sufficient in these tests. For the above 165-mile stretch, for instance, wires only 100ft. high were employed.

THE FIFE ELECTRIC POWER COMPANY.

The pioneering station of the above company was formally opened on the 16th inst., and we gave a brief description of the ceremony in our issue for Aug. 18. Through the courtesy of the consulting engineers, Messrs. Bramwell and Harris, and the chief contractors, Messrs. Bruce Peebles and Co., we are now able to lay before our readers more particulars of the work which has been done towards the development of power supply in the county of Fife. It will be remembered that the Fife Power Company's Bill was passed during the parliamentary session of 1903, the company being authorised to supply power to individual consumers outside the area of supply of existing authorised distributors, and also to supply in bulk to authorised distributors within the power company's area. This area includes the whole of the county of Fife, certainly the most important industrial area in the East of Scotland, the 504 square miles being studded with collieries, textile mills brick and lime fields, quarries, and engineering and iron works. These industries are, moreover, so situated as to receive the utmost benefit from an electric supply company operating on modern principles, for they are for the most part scattered rather than grouped closely round any one centre, a condition pointing clearly to high-tension transmission. Another great outlet which the company will no doubt find, is supply to local authorities mainly for lighting purposes. A glance at a map will substantiate this, for it will be seen that in the whole area there are at present but two towns—viz., Kirkcaldy and St. Andrews—which have their own generating stations, the former having both lighting and tramways, and the latter lighting only. In view of the great number of towns of small medium size in the county, a large demand may certainly be looked for from this source.

In the scheme as presented to Parliament the sites of five generating stations were given. Up to the present, however, the work on these sites has not been commenced, and the station opened near Dumfermline is really a pioneer station to meet the demand in the surrounding neighbourhood. This is indicated by the block plan of the site (Fig. 1),

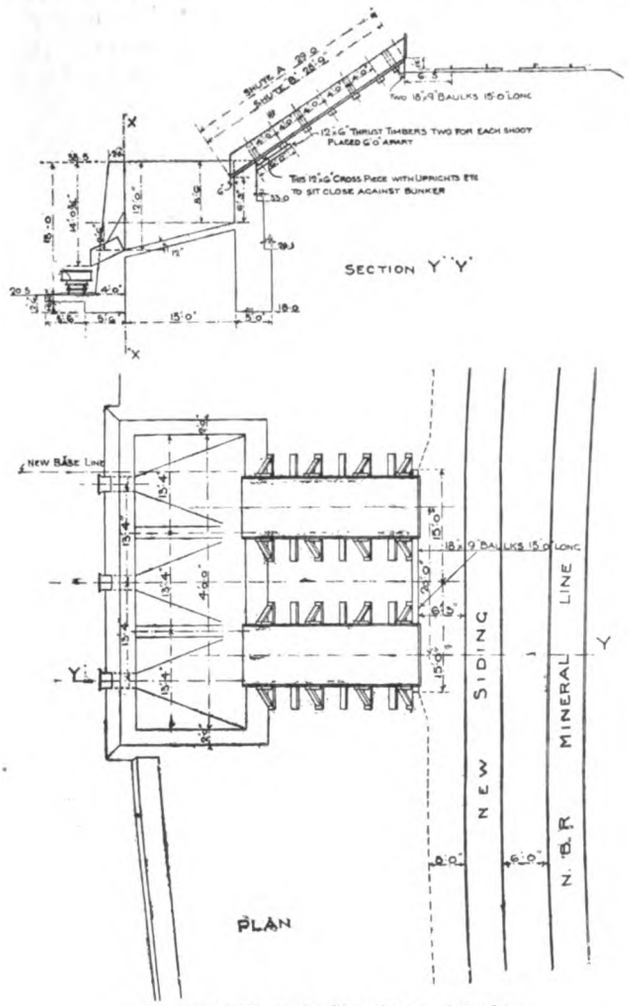

FIG. 2.—Details of the Coal Shoot and Bunkers.

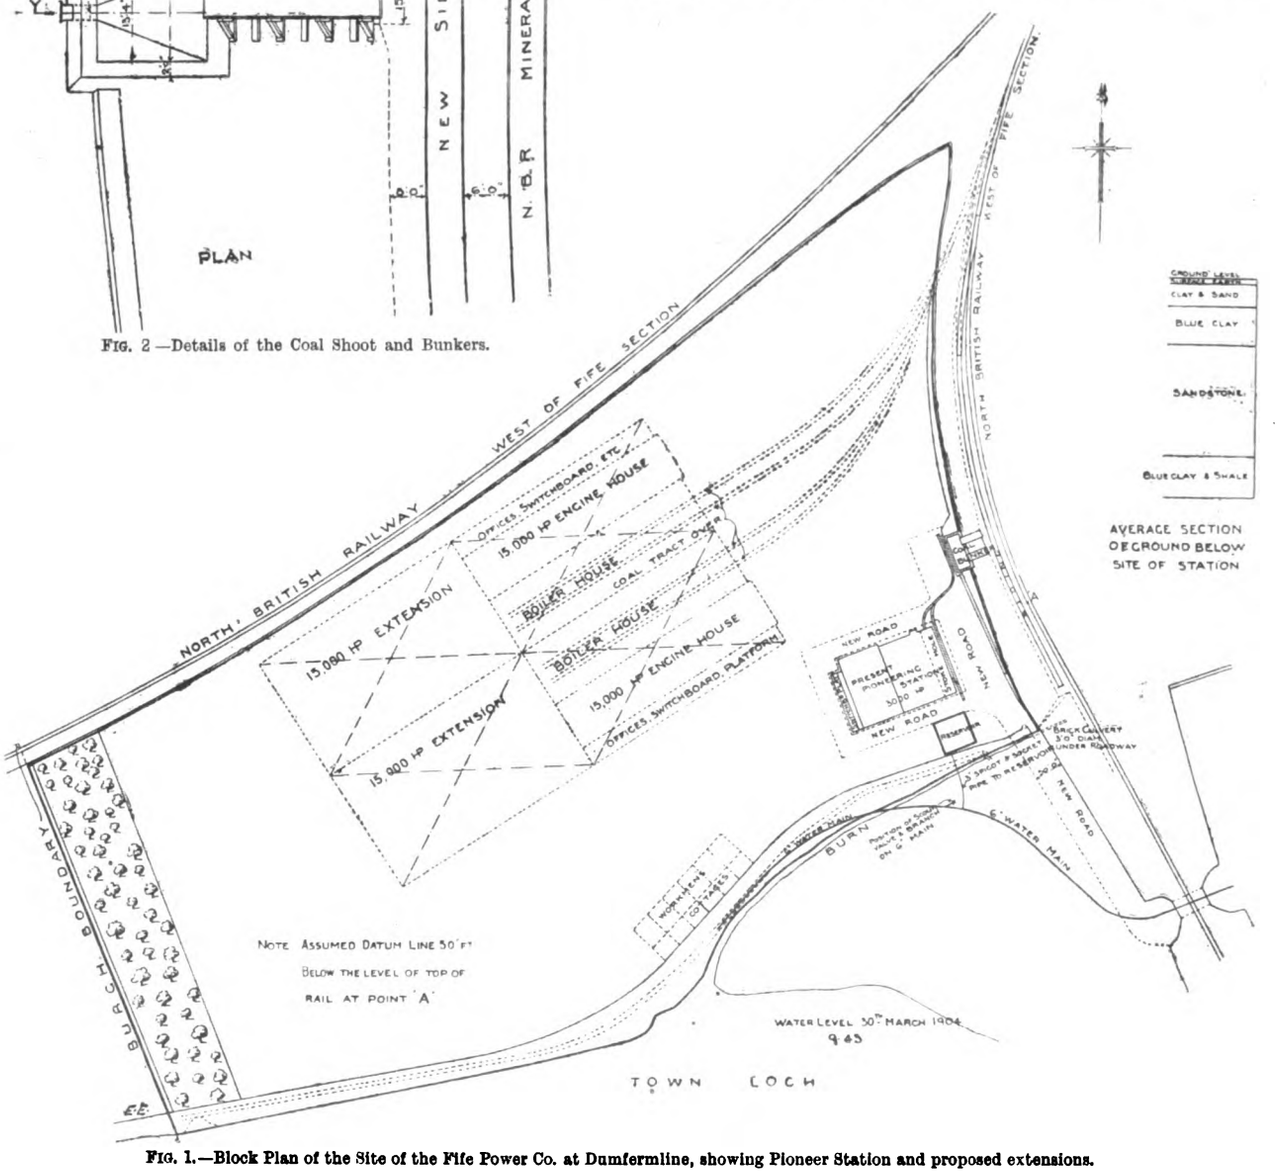

FIG. 1.—Block Plan of the Site of the Fife Power Co. at Dumfermline, showing Pioneer Station and proposed extensions.

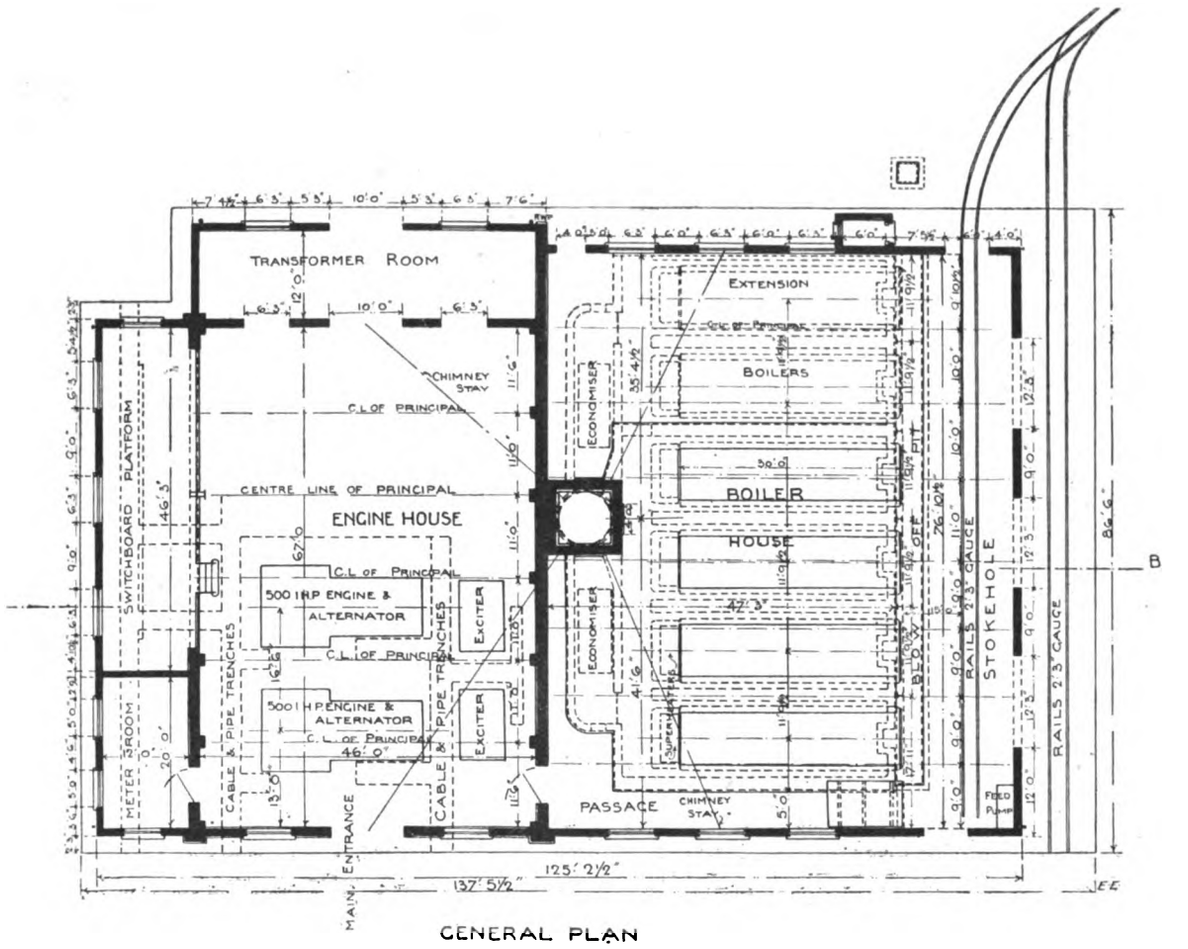
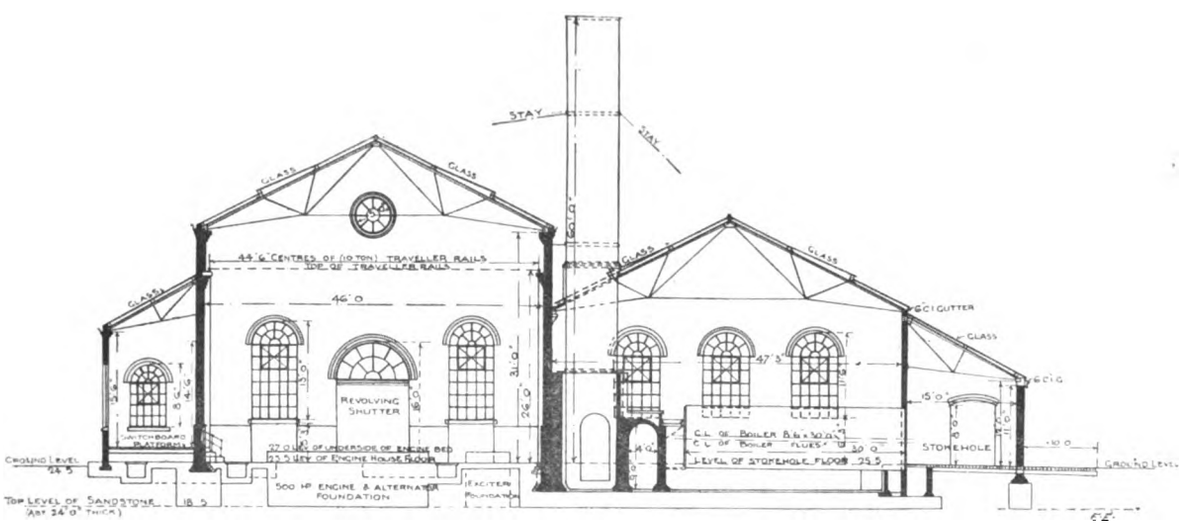
Digitized by Google

which shows that after the present buildings have been filled with machinery a 30,000-h.p. station will be equipped near by. The capacity of the site would not then be exhausted, as there is room for a plant of even double the above capacity. The large units which are now possible will enable an extremely economical station to be erected, as the coal and water facilities of the site are excellent. At present the coal is not taken directly into the boiler-room, but is delivered from the railway into a coal bunker, from which small trucks carry the coal into the stokehole. The details of this coal bunker can be seen in Fig. 2. The works adjoin a branch of the North British Railway, which runs along the high embankment seen to the right of the plan (Fig. 1). The town loch, which is close to the works, is looked upon as likely to afford a supply of condensing water for the large station when erected.

This power station erected at Townhill, near Dunfermline, has been built and equipped complete by Messrs. Bruce Peebles and Co, of Edinburgh, to the plans and under the supervision of Messrs. Bramwell and Harris, the consulting engineers of the company. The general arrangement of the same can be seen from Figs. 3, 4, and 5, which give respectively the plan of the station, a sectional elevation of the buildings, and a section to show the arrangement of the plant. The boiler-house is at present equipped with four large Lancashire boilers, each capable of evaporating 8,500lb. of water per hour, fitted with superheaters. Each boiler is 30ft. long over the end plates, and has an inside diameter of shell of 8ft. 6in. The working pressure is 160lb. per square inch. Two fire flues are fitted as usual, the vertical centre lines of these flues being placed 4ft. 1½in. apart, and the horizontal line being placed 5½in. below the centre of the boiler. The external diameter of the fire flue is 3ft. 7¼in. except for the two last rings at the back; the inner one of these rings is conical, diminishing from 3ft. 7¼in. at its front end to 3ft. 1¼in. at its back end, where it joins the last ring, which is also 3ft. 1¼in. diameter in each flue. Towards the back there are placed six



GENERAL PLAN



SECTION ON LINE A B

FIGS. 3 AND 4.—Plan and Sectional Elevation of the Fife Power Station.

Digitized by Google

Galloway tubes at angles of 60deg. alternately on each side of the vertical centre line. Each boiler is provided with the customary valves, pressure and water gauges, blow-off cock, etc. The superheater is of sufficient capacity to impart 60deg. of superheat to the steam produced by the boiler when evaporating the full 8,500lb. weight of water per hour.

The pipework was sub-contracted by Messrs. Bruce Peebles to the Sir Hiram Maxim Engineering Company, and is of standard construction. The steam-main is on the ring principle, and is constructed of welded solid-drawn steel.

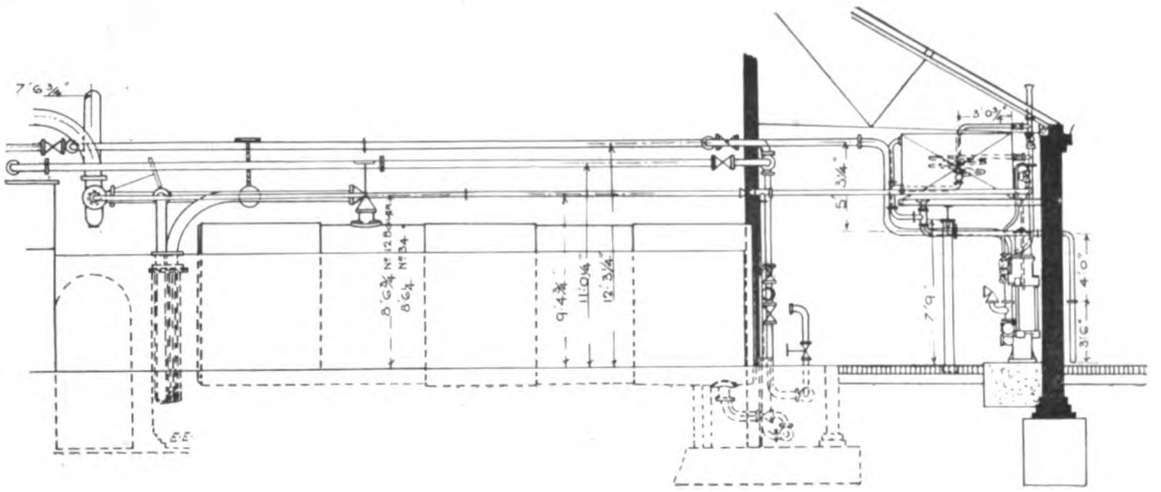


FIG. 5.—Section of the Boiler House, showing Pipe Connections.

A 7in. pipe is taken from each boiler stop valve to the superheater with a by-pass, and this is conducted into the main heater in the boiler-house. This heater has to cross over pipes to a smaller heater in the engine-house, steam separators being provided at the point where the cross-over points connect the engine-house main; the steam is taken from the upper side of this main direct to the separators on the engines. The exhaust of the four engines are connected to the main exhaust pipe of riveted steel 20in. in diameter, which is carried up outside the engine-house and terminates at the exhaust head. Condensing arrangements are not at present installed. The water supply is drawn from an overhead feed tank, which is fed by a Peebles motor-driven pump from a reservoir outside the station, shown in the exterior view. The water can be delivered from the overhead feed tank either direct to the boiler or through the economiser. The blow-off and feed pipes are carried along a trench in front of the boilers as usual. The boilers are also fitted with ejectors, which act as a stand-by feed. All high-pressure valves are of Messrs. Hopkinson's make.

As will be seen from the plans and from the photograph (Fig. 6), a tall chimney has not been built for the present station. Instead of this a low steel stack is used, and induced-draught apparatus is relied on to give the necessary draught. It is claimed that by this system the steaming capacity of the boilers is increased considerably above normal working capacity without damaging the boilers. Moreover, that the cheapest kind of fuel can be thoroughly burned, thus practically abolishing the smoke nuisance. The draught being mechanically produced is independent of any atmospheric conditions, and the system is more elastic in operation than natural chimney draught, which enables the fireman to regulate the supply of steam as desired.

The plant consists of Sturtevant steel plate exhausting fan, provided with patent water-jacketed bearings by means of which the fan is kept in perfect working order when handling gases at temperatures varying from 150deg. to 80deg. F. The fan is connected to the base of the iron stack by a mild-steel connection, and the outlet from the fan is connected to the stack, which is outside the roof of the boiler-house. Regulating dampers are fixed to these connections, so that, if desired, the boilers can also be worked with natural draught. The motor driving the fan is provided with patent controller fitted with automatic no-load and overload releases, and capable of regulating the speed of the fan from 350 r.p.m. to 420 r.p.m. as desired. The fan being connected to the extreme end of boiler flues, close to the base of chimney, when in operation creates a partial vacuum in the flues, and thus draws the air through the fires in the boilers, the desired vacuum being maintained according to the speed of the fan. The economiser, which, in connection with all the other auxiliary apparatus, is driven by a Peebles continuous-current motor driven from the exciter sets, is of standard construction, consisting of 144 tubes arranged in two groups of 72 tubes each, six tubes wide. The tubes are 9ft. long and 4in. internal diameter, being forced into the top and bottom

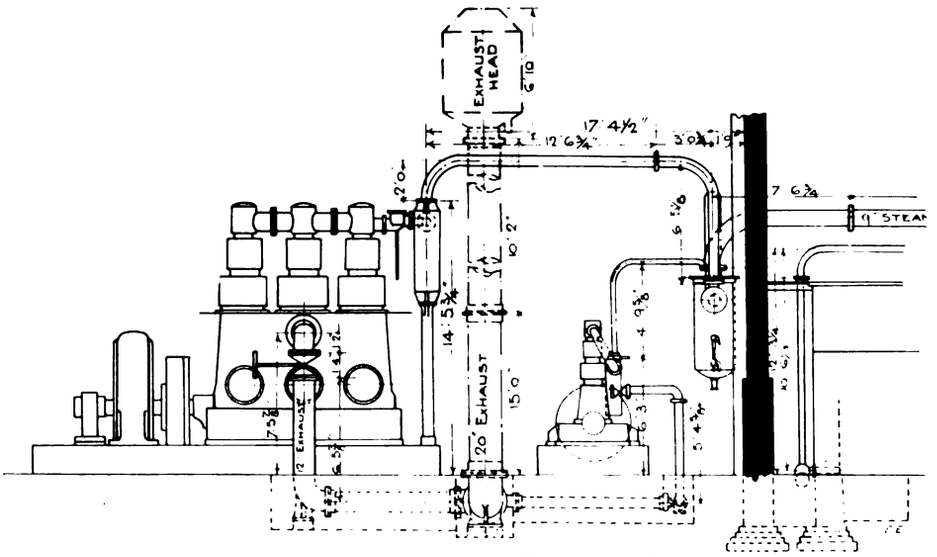

FIG 5A.—Section of the Engine Room, showing Pipework.

Digitized by Google

boxes by hydraulic pressure, the joints being metal to metal. Self-acting scrapers with overlapping joints and chilled edges are provided. The economiser works at an ordinary pressure of 150lb. per square inch, and it is, moreover, so arranged as to deal in a satisfactory manner with cold feed water—*i.e.*, water at about 50deg. F., and when supplied with water at this temperature there is no sweating of the tubes.

The engine-room equipment is shown in Figs. 7 and 8. As will be seen from these that all the engines are of the Willans type, manufactured at Messrs. Willans and Robinson's Rugby works. The alternator engines (Fig. 7) are of the triple-expansion three-crank type, which give such excellent results as regards parallel running. The exciter engines (Fig. 8) are of the two-crank compound type. To each of the two main engines is coupled a 400-kw. Bruce Peebles two-phase alternator running at 50 periods and 3,000 volts. This output is given on a basis of the temperature rise after six hours' full-load run not exceeding 60deg. F. As regards regulation, the

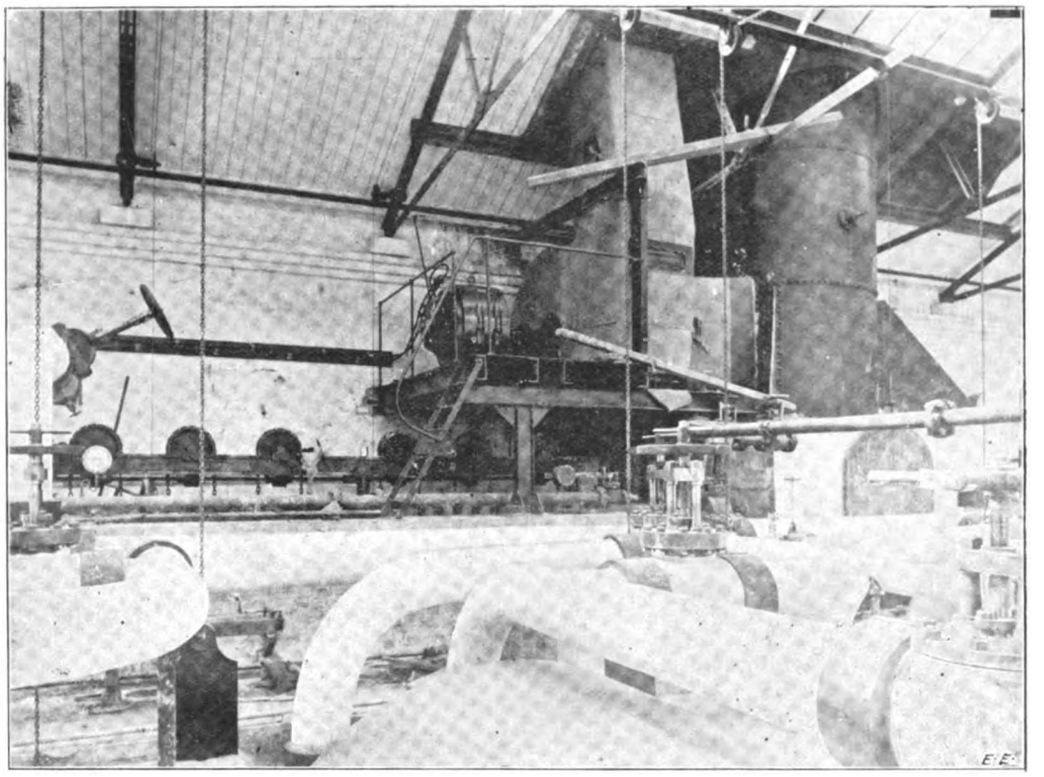

FIG. 6.—View of the Top of Boilers, showing Electrically-Driven Induced-Draught Fans.

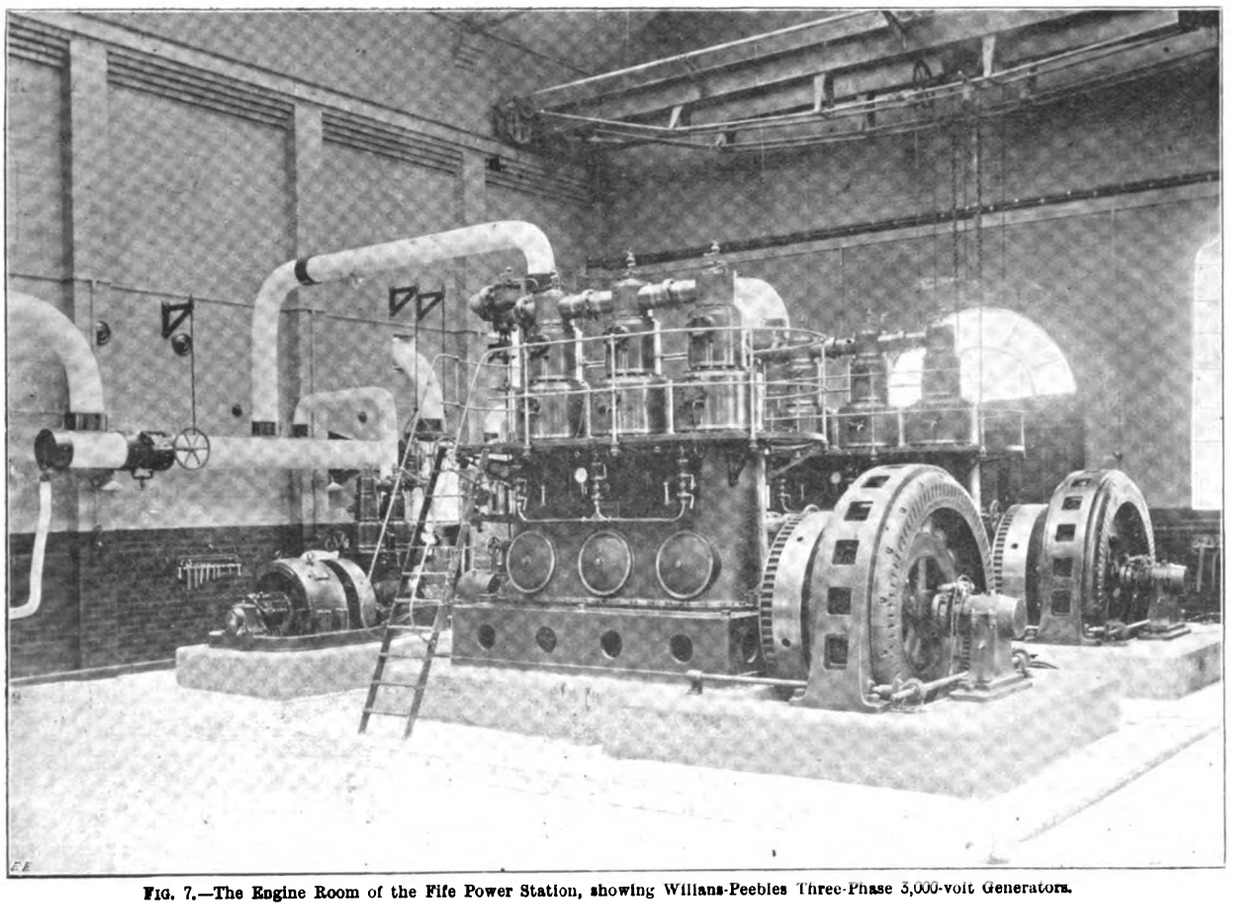

FIG. 7.—The Engine Room of the Fife Power Station, showing Willans-Peebles Three-Phase 3,000-volt Generators.

Digitized by Google

engine governor is so efficient that the speed of the set will not rise above or fall below the normal by more than 5 per cent. momentarily or 2 per cent. permanently when full load of thrown off or on. The alternators are of the firm's standard construction with rotating fields. The field poles, which are bolted to the rim of the magnet wheel, are wound with bare copper strip on edge, adjacent layers being insulated by special paper. As the windings and field coils all round the magnet wheel are in series, and as there is a considerable number of turns on each pole, it will be seen that the voltage between turns of the winding is very small indeed, so that the special paper used provides ample insulation. This method of winding gives a very handsome mechanical job. The armatures are stationary, and are built up of stampings of soft iron, having nearly closed slots formed at the periphery. The windings are disposed in these slots and insulated with presspahn, mica, and special varnish. The winding is of the two-phase type. The two exciter sets consists each of a Peebles-Willans 45-kw., 110-volts, continuous-current combination, and these are used for excitation for the main alternators and also for driving the various subsidiary motors about the plant.

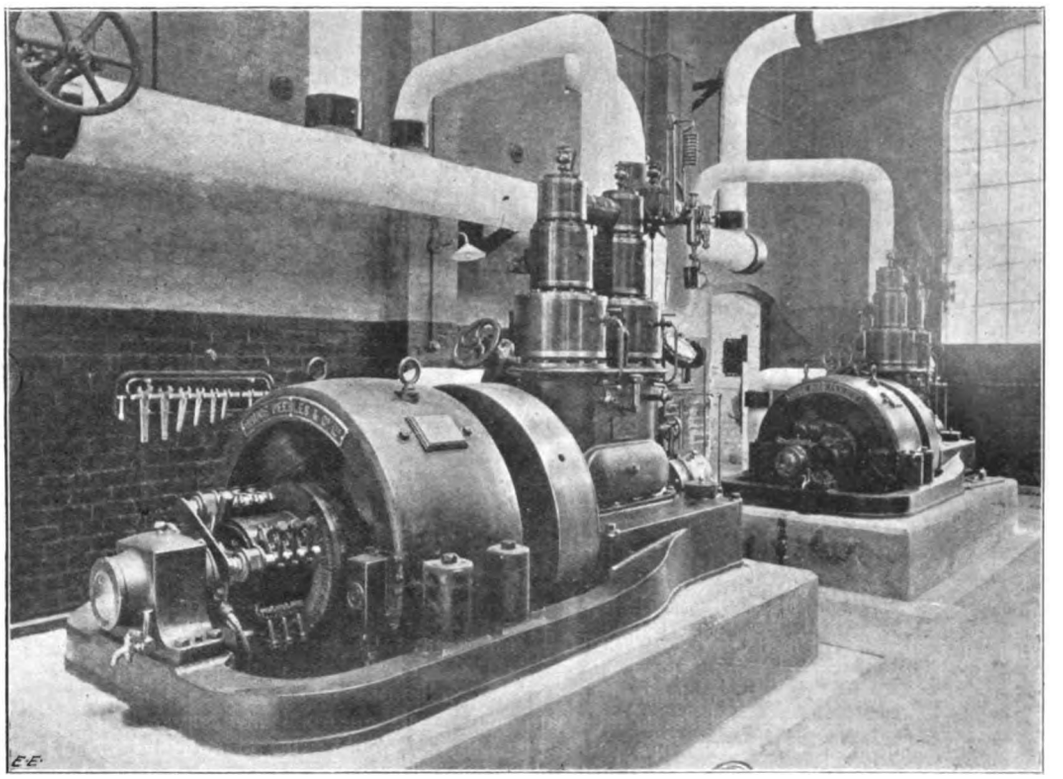

FIG. 8.—The Willans-Peebles Direct-Current Generators for Excitation and Auxiliary Motor Circuits.

The main switchboard (illustrated in Figs. 9 and 10) includes two alternator panels, each of which has an exciter panel beneath it, a synchronising panel, and three complete feeder panels. Two sets of 'bus bars are provided, lighting and power bars being normally separate. Either alternator can be plugged to either separate bar. As will be seen from the photograph of the back of the board, bars and connections of opposite polarity are separated by substantial slate partitions, and fireproof insulation is used on all insulator conductors. Each feeder panel consists of three sub-panels, two of which are normally in use, while the third is a spare. This third panel controls an additional lead, which may be plugged to the 'bus bars and

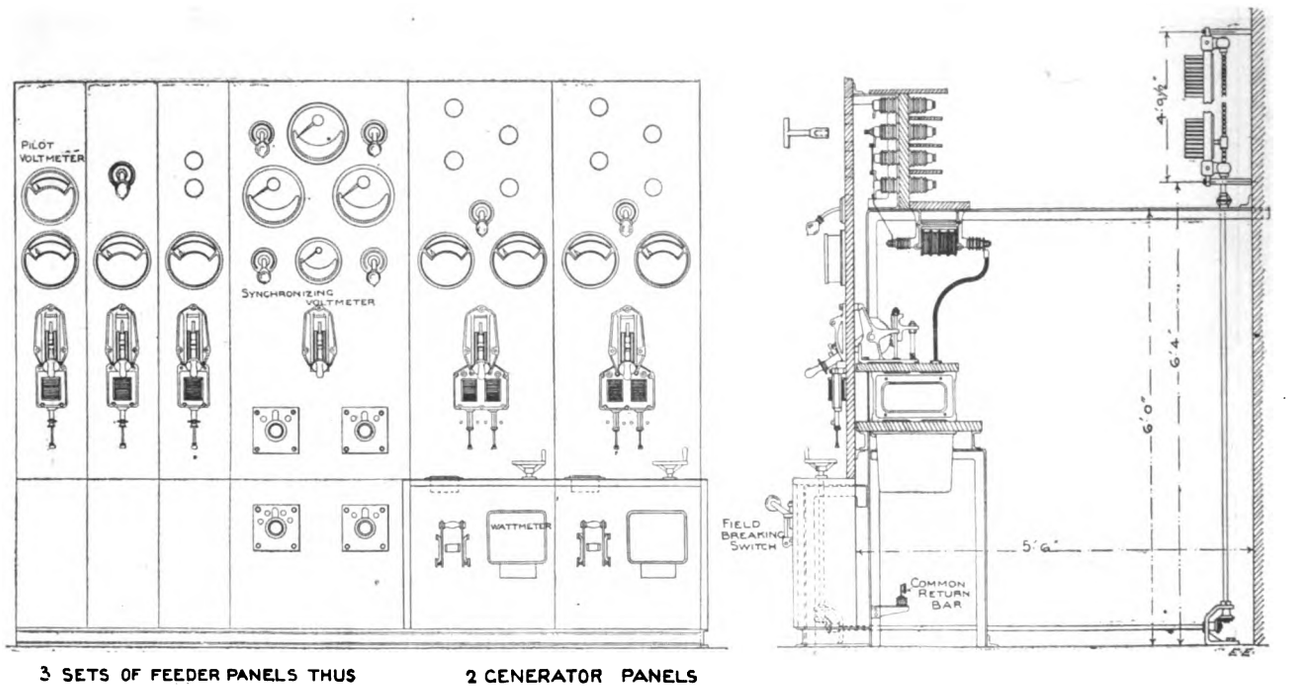

FIG. 9.—Front and Side Elevation of the Main Three-Phase Switchboard of the Fife Power Co.

Digitized by Google

switched into service should one of the others break down. As usual, the alternating panels are arranged on the right-hand side facing the board, the synchronising panel in the middle, and the lighting and power feeders to the left. Each alternator panel is provided with four plugs, two ammeters, and circuit breaker, while the adjoining exciter panel is provided with a vertical ammeter, shunt-breaking switch, rheostat, and wattmeter. The synchronising panel is provided with voltmeters for the incoming alternator, and also one each for the lighting and power 'bus bars. In addition, synchronous voltmeter and lamps are provided, and an oil switch for coupling the incoming alternator to either set of bars. Each feeder panel is provided with an ammeter, pilot voltmeter for each phase, lamps and circuit breaker, also plugs for plugging in spare feeder. All circuit breakers are of the oil type. In addition to the main board, there is a small exciter board consisting of three panels. An interesting feature of the main board which

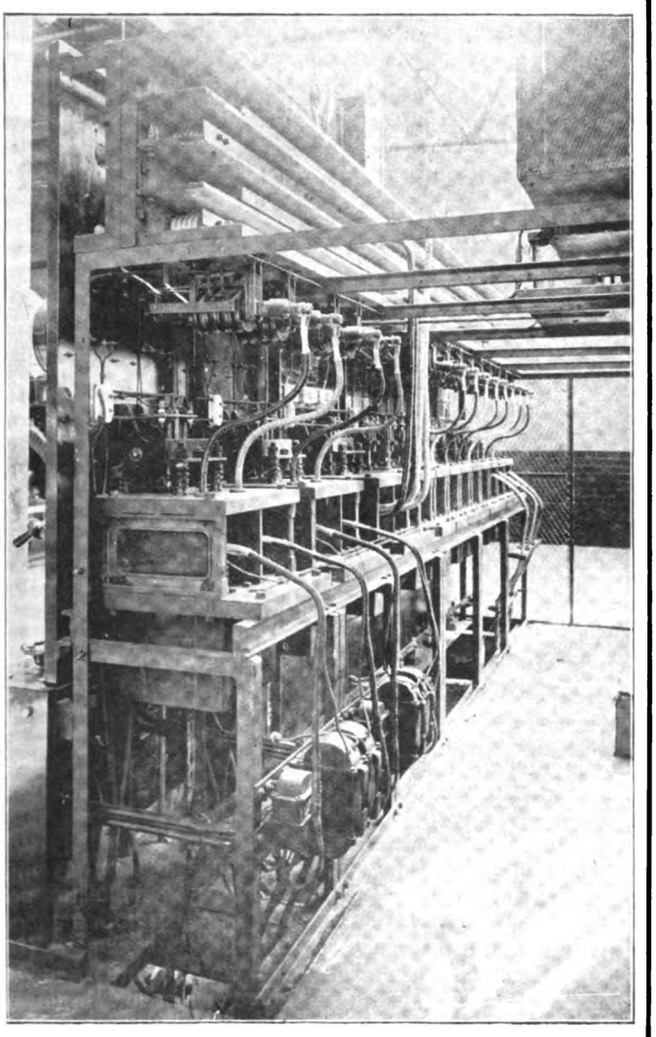

FIG. 10.—View of the Back of the Switchboard.

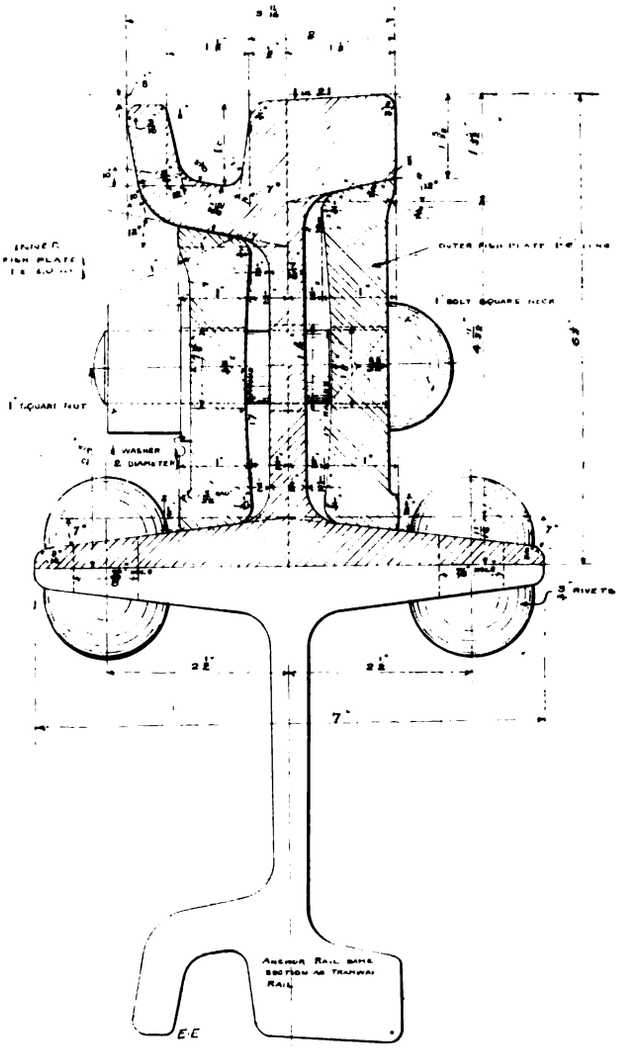
may here be mentioned, is that the lamps shown above the circuit breakers indicate from a distance whether the circuit breaker is closed or not. These lamps are operated by exciter current, and are switched on or off by auxiliary contacts on the circuit breaker itself.

The station is now completed, and a considerable number of mains have been laid to supply works in the Dunfermline neighbourhood. The whole of these mains have been supplied and laid by the Callender Cable and Construction Company, who have used for the purpose 0·1 square inch concentric, high-tension, fibre-insulated, lead-sheathed, steel-armoured cable. It has been laid direct in the ground, three being in one trench at a suitable distance apart, with marker board 3in. above.

The company are now supplying power to several works in the Dunfermline district. Further developments of the system, both as to supply in bulk for lighting and also to tramways, are likely to be arranged more promptly now that a supply is available.

ERITH ELECTRIC TRAMWAYS OPENING.

The opening ceremony of the Erith tramways on Saturday last was attended by a large company, including representatives from nearly all the London daily papers. This showed the interest taken in the system, which is a link in what will eventually be a large tramway network extending from London down through a large area in Kent. The company met at the car-sheds on the Walnut Tree-road, Erith, at 10.45 a.m., and had a good opportunity of inspecting the tramcars, the car-sheds, as well as the workshops and the offices from which the Erith tramways will be controlled. Before starting on the decorated cars to inspect the lines, an address of welcome was given by Mr. F. A. Stone, J.P., the chairman of the Erith Urban District Council, who afterwards declared the tramways open for public traffic. A procession of four decorated



The Anchor Rail Joint used on the Erith Tramways

cars then went along the three routes, which are shown in the map given on p. 258 of our last week's issue. The first route to be traversed was that along the Lower-road to Abbey Wood. On this is the bridge over the South-Eastern Railway and road diversion which replaces the previous level crossing. The construction of the bridge and the laying-out of the approaches form an engineering work which was greatly admired, and which will be of great value to the general users of the road quite apart from the tramway passengers. The view from the top of the bridge commanded nearly all the manufacturing works of Erith, and showed what great possibilities there are for development in this direction now that cheap power and a convenient tramway system are available. After going to the Abbey Wood terminus the car returned to the power station, and the guests inspected the same. We were particularly struck with the improvements which had been made by the extension of the engine-room. The front of the high-tension switchboard, on which the instruments and controlling

Digitized by Google

handles are placed, has been moved back, and stands in openings in what was originally the outside wall of the station. The high-tension switch and fuse gear is now contained in an extension to the building. It is greatly to the credit of the electrical engineer, Mr. G. E. Heath, that the moving of the switchboard and changing over of all the high-tension gear and connections were made without the slightest interruption to the supply. After inspecting these works, the other two routes to the Northumberland Heath terminus and to the North End terminus respectively were traversed. The cars travelled smoothly over the lines, and there was no hitch whatever during the trial run.

At 1 p.m. the company adjourned to the Public Hall, where an inaugural lunch was held, to which ladies were invited. The chairman of the Council, Mr. F. A. Stone, J.P., presided, and proposed the usual loyal toasts. Eight other toasts were on the lists, and two more informal ones were added, so that the speechmaking was not lacking in quantity.

The Mayor of Woolwich proposed "Success to the Erith Tramways," and hoped that the London County Council would soon complete the tramways they had powers to construct in the south-eastern side of London, and that people would then be able to travel through to Gravesend without a change of car. He thought the work would be undertaken as soon as the Greenwich power station was completed. As regards power supply, he was not clear as to the advisability of the London County Council making themselves responsible for supply outside their area, but thought that one great station might be constructed by a combination of the Councils of Bexleyheath, Erith, Dartford, and Gravesend. The costs would be lowered by such a combined scheme, and transit would be cheapened. He hoped the profitable stage of tramway undertaking would soon be reached, and that on the completion of the connections to London produce as well as passengers would be carried.

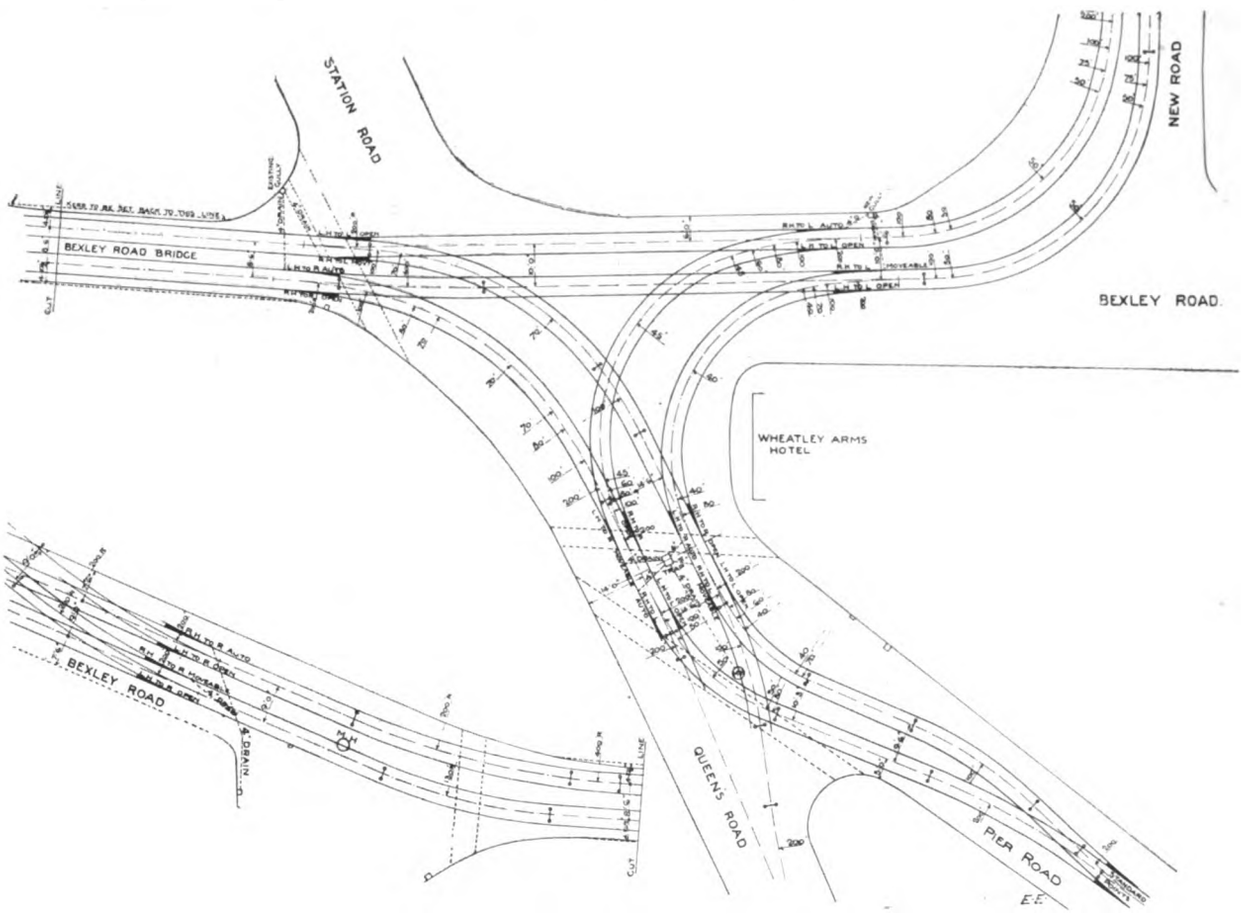
The Chairman, responding to the toast, said it had naturally been a great labour to bring the tramways to the state they were in that day. The Council had devoted a good deal of its time to the question for some three years. They felt, as the Mayor of Woolwich had pointed out, that the London County Council should link up their tramways with London, and when that day arrived their tramways would be a certain success. Until that time arrived they must trust to the loyalty of the citizens to make it pay. They were glad to be linked up at all events with Bexley, although they had not secured through running powers yet. They hoped to secure them, and when that day arrived it would be a benefit both to Bexley and to Erith.

Councillor H. Cannon complimented Messrs. Hawtayne and Zeden on the work they had done as consulting engineers to the Council. Neither time nor trouble had been spared to make the system a success.

Mr. W. C. Hawtayne responded on behalf of the firm, and gave credit to the individual members of his staff who had been responsible for the different sections of the work. He presented the chairman of the Urban District Council with a handsome silver bowl as a memento of the occasion.

The contractors, the Electric Lighting and Tramways Committee, the officers of the Council, the guests, the Press, and, finally, the chairman were all duly toasted.

Mr. Hawtayne was presented with a free pass over the Erith tramways by Councillor Grey, and in returning thanks expressed the hope that the pass would in time be available to Gravesend, if not to Maidstone and Dover.



Lay-out of Special Work at the Crossing near the Council's Office at Erith.

The company then adjourned to witness an interesting trial of the Westinghouse magnetic brake which was made on the heavy grade of Walnut Tree-road. A car was allowed to run down this grade with the trolley off the trolley wire and with the controller handle in such a position as to give the maximum braking effect. Starting from rest, the car reached such a speed that the motors began to generate, which applied first the slipper brake on the rail, and then by the dragging action of the slippers the wheel brakes were applied. These stopped the car, but the brakes were again released as soon as the current ceased. The whole cycle took place while the car was travelling down about 5ft. of the hill. This alternate starting, braking, stopping, and starting again clearly showed how sensitive the braking arrangement was. A speed of about one mile per hour was sufficient to make the motors act as generators and to apply the slipper brakes. A further trial was made in which the car was running down the grade at full speed in order to see how far it would run if the brakes had been applied, as would

Digitized by Google

be the case for an emergency stop. In spite of a running speed of about 15 or 16 miles an hour, the car was pulled up in about one half of its length.

The guests coming from a distance then had an opportunity of comparing the comfort and speed of the tramcars with that provided by the South-Eastern and Chatham Railway Company's service, with which the tramways will compete. It is now, of course, possible to obtain communication with the London tramway system, with one or two changes, taking the car to Northumberland Heath, thence traversing the Bexley system to Woolwich and on, but it is the more direct routes, *vid* the Lower-road and Woolwich-road, yet to be constructed, that will be of the greatest benefit to the district. From the Bexley tramways a connection will also shortly be obtained with Dartford by means of the new light railways just commenced by the Dartford Urban District Council, which run as far as Horn's Cross. The connection between Horn's Cross and the Gravesend tramways has had to be abandoned through the opposition of the South-Eastern Railway, but a further application for the construction of this portion of the line will, no doubt, be successfully made after the authorised lines have been opened.

We are able this week to give an illustration of the special work supplied by the Hadfield Steelfoundry Company for the most important crossing on the system. This is at the top of the new Walnut Tree-road, where the lines to Bexleyheath and down Pier-road to North End branch off. The lay-out of this special work, which has been executed in manganese steel, is shown clearly in this illustration. The other drawing reproduced is of the joint employed between the rails.

Mr. J. W. B. Carruthers has acted as clerk of works throughout the construction of the permanent way and erection of the overhead equipment, and Mr. J. Pluck has filled a corresponding position during the construction of the bridge.

The Council have selected, from among a large number of candidates, Mr. A. Coveney to act as general manager of their tramways system. Mr. Coveney is a Kentish man, and received his early professional training in the county. He was at one time chief assistant engineer to the Isle of Thanet Light Railways, and subsequently became general manager of the Ashton-under-Lyne electric tramways, holding that position for 3½ years, during which time he acquired much popularity as a capable and urbane official. The general regret expressed by the Tramways Committee when Mr. Coveney resigned his appointment at Ashton to enter upon his duties at Erith augurs well for the success of his management of the new undertaking. We understand from him that the traffic on Saturday and Sunday last was exceptionally heavy, the takings being over £60 and £70 respectively. The steady returns since then show that the system is being well used by the inhabitants.

In conclusion, we have to thank Messrs. Hawtayne and Zeden for their assistance in the preparation of our descriptive article last week.

THE MAINTENANCE OF COMMUTATORS AND BRUSHES.

BY S. LEES.

(Concluded from page 274.)

Fig. 5 is illustrative of type 2. The emery wheel, A, is fixed on the shaft, B, which is carried by the bearings, C C, supported on the standards, D^1 D^2. The standard, D^1, is provided with a V slide on which it may be traversed across the bar, E, to suit different depths of cut. The base of the slide is carried by the sleeve, F, on which is formed a half nut, G, engaging the screwed end of the rod, H. A handle is fitted to rod H, by means of which the wheel, A, can be traversed along the commutator in either direction. The shaft, B, is slotted at M to enable it to travel through the bearing, C, and driving pulley, O; and the bearing standards, D^1 D^2, are telescopic, so as to admit of vertical adjustment for different heights of commutators. In the sketch the machine is shown fixed to the bedplate of the dynamo by an adjustable clamp, P.

The writer experienced some little trouble in getting a satisfactory belt drive with this type of grinder, but finally got over the difficulty by mounting the driving motor, starting switch, etc, on a portable stand, as illustrated in Fig. 6. The framework is built up of 3in. by 3in. well-seasoned pitch pine, all joints being mortised and bolted

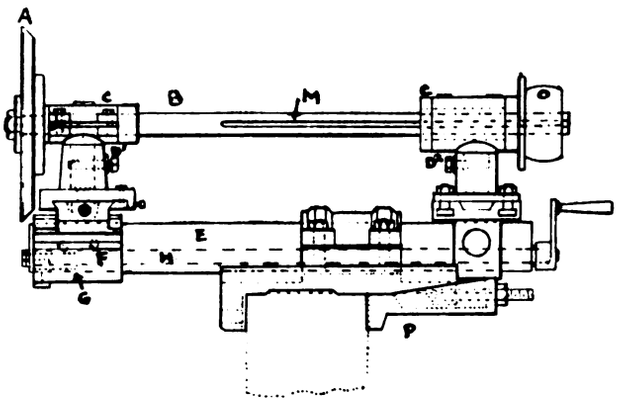


FIG. 5.

together. The motor is of the protected type, giving 1 b.h.p, the starting switch being provided with overload and no voltage release coils. The details of the sketch may, perhaps, prove self-explanatory. The compactness and portability of the arrangement will be readily appreciated by anyone who has done much commutator truing, and its advantages over any other method where the

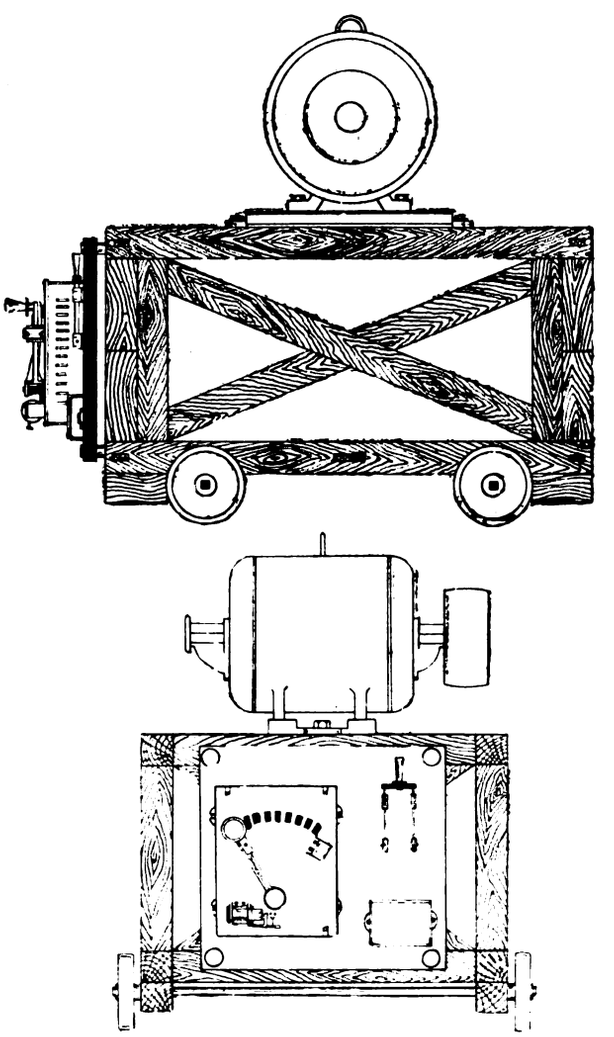

FIG. 6.

driving motor, starter gear, etc., require fixing in position before using each time, are obvious.

Before commencing to true up a commutator a large piece of stiff paper should be placed in the commutator pit to receive turnings, dust, etc., and the terminal blocks and any other bare current-carrying metal work kept well covered to prevent copper dust from being deposited

Digitized by Google

thereon. The bearings should also be protected, in order to exclude dust and grit from the oil-wells. It is a good plan to fix a piece of stiff paper over the end of the armature winding from where the connections to the commutator are made. This will effectually prevent turnings, etc., from lodging between the windings. A dab or two of shellac varnish will hold the paper covering securely in place.

A useful tool designed by the writer for cleaning commutators is shown in Fig. 7. It is made up of well-seasoned pine, the two parts being glued and dowelled

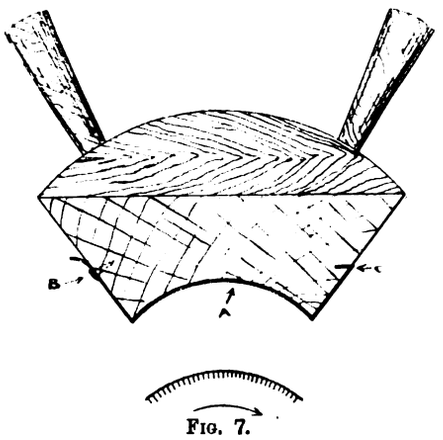

FIG. 7.

together. To use, a piece of emery cloth is placed in the hollow of the tool, one end of which is fixed in the saw-kerf at *a*, the other end being fastened down by means of two or three drawing-pins. A small quantity of oil should be smeared along the forward edge of the emery cloth to collect copper and emery dust, as these substances have a tendency to irritate the operator's nose and eyes. The tool is held firmly to the surface of the commutator, as indicated by the arrow—*i.e.*, against the direction of rotation of the commutator—and should occasionally be given a lateral motion.

A commutator burnisher made by the Ediswan Company is illustrated in Fig. 8. In operation, a strip of emery or polishing cloth, the same width as the burnisher, is cut, and one end inserted under the clip at the front end; it is then turned back under the flexible backing and applied to the commutator. The flexible backing is made in such a manner that it easily adapts itself to the curve of the commutator, but will not fall into depression on the surface. Thus the whole surface is evenly scoured with emery cloth to any degree of roughness required and afterwards polished.

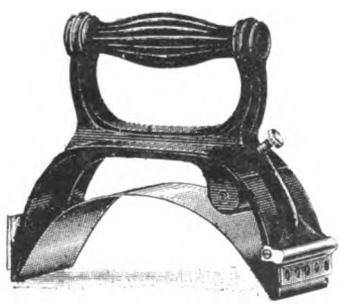

FIG. 8.

Another method of scouring commutators is to use a brick or block of carborundum. These blocks, measuring about 10in. by 4in. by 4in. can be obtained in various grades from 10's to 80's. The writer was connected with a large station across the water where seldom anything else but "the brick" was put on the commutators, and, as may be imagined, quite a large number were used, as the frequent application of the brick only aggravated the formation of "flats." This method, whilst being convenient for a temporary job, is somewhat barbarous, as the commutator is only rough scoured, and when using, if the brick is not cleared of the copper cuttings, very frequently the commutator gets scored and fluted badly.

In order to reduce the wear of commutators and brushes to a minimum, the pressure on the brushes should be as light as possible consistent with sparkless commutation. This is most important where copper gauze brushes are used, as undue pressure on the brushes causes the commutator to get scorched, owing to the foot of the brush having become fused together in a more or less solid piece, thereby rendering trimming a daily operation, whereas, if properly set, and given a fair amount of attention when working, copper brushes should not require trimming oftener than once every two or three months. A brush jig is a useful tool for holding the brushes in when being trimmed. This tool may be either of wood or metal; if of the former a hard wood such as birch or teak is best, the top of the jig being slipped with a guide-piece of steel set to the angle it is desired to trim the brushes to. When using, care should be taken not to take a back-stroke with the file; any stray strands of wire which may remain after filing are best removed by means of a pair of scissors or tinsmith's snips. One form of jig for holding two brushes is shown in Fig. 9.

Carbon brushes, which are now very extensively used, being hard and unyielding—unlike copper, gauze, or wire—require bedding very truly to the curvature of the commutator in order to get sparkless running. If not bedded properly, when working, the face of the brush gets red-hot, and, finally, the brush crumbles away altogether. The best way to bed carbon brushes is to slip a piece of medium,

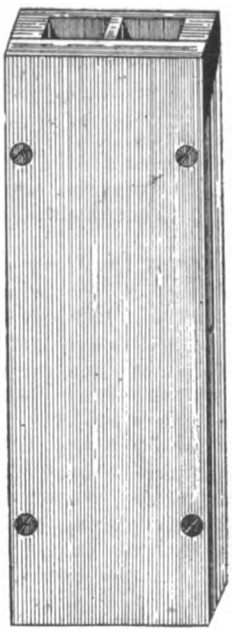

FIG. 9.

say 1's, glass cloth or paper (cloth is preferable) between the brushes and the commutator with, of course, the business side of the glass cloth towards the brushes, and work it forwards and backwards until the brushes are bedded accurately to the curvature of the commutator. The glass cloth should be kept quite close to the face of the commutator during the operation, otherwise, if allowed to chatter or kink the brush gets chamfered down at the heel and toe, thus reducing the effective collecting area of the brush. These remarks apply equally well to carbon brushes of both the block and slab types, though the latter are not now much used owing to their fragility under working conditions. The best qualities of carbon brushes have a fine close grain, wear slowly and uniformly, and present a very soft frictional surface. Carbon brushes are usually plated with copper or nickel on the parts which come into contact with the brush-holder, and care should be taken that the plating is never allowed to come in contact with the commutator, the plating being stripped off as the brush wears away. For a good quality of carbon brush the current density to be used may be taken at about 30 to 50 amperes per square inch of sectional area, this varying with different types of machines and conditions of working.

An improved type of metal brush, which possesses many advantages over the ordinary gauze or bunched wire type, consists of a number of very thin laminations of an anti-friction metal having a higher electrical resistance than that

TABLE A.—PARTICULARS OF BRUSH-HOLDERS AND BRUSHES.

Size of machine. No.	Kw.	Volts.	Brush-holder.	Brushes. Quality.	Actual wearing length.	Pressure on brush.	Type.	Wear.	Remarks.
1	3	220	Swinging arm type	B	1in.	1½lb.	Fixed block or wedge type	Average life = 200 running hours	Commutator blackened frequently, necessitating regular cleaning. After three months' service, commutator worn out of truth nearly ¼in.
2	7	540	Swinging arm type	A	1in.	1½lb.	Fixed block or wedge type	After 5,000 running hours, wear = ⅛in.	Commutator, after nearly two years' service, in excellent condition. No cleaning required.
3	20	440	Swinging arm type	B	1in.	1½lb.	Fixed block or wedge type	Average life = 200 running hours	Commutator trued up after 1,200 running hours.
4	20	440	Swinging arm type	A	1in.	1½lb.	Fixed block or wedge type	After 5,000 running hours, wear = ¼in.	Commutator, after nearly two years service, in excellent condition; cleaned occasionally.
5	100	550	Fixed box type	C	1½in.	5lb.	Floating or box type	Average life = 1,500 running hours	Brushes trimmed—*i.e.*, bedded—on an average about once every 100 hours' run. Commutator trued up after 3,000 running hours.
6	100	550	Fixed box type	D	1½in.	5lb.	Floating or box type	After 2,000 running hours, wear = $\frac{5}{16}$in.	Commutator in excellent condition, no cleaning required. Since the initial bedding the brushes have not been trimmed in any way, the brush faces being in perfect condition.
7	100	550	Fixed box type	E	1½in.	5lb.	Floating or box type	After 200 running hours, wear = $\frac{1}{32}$in. (about)	Brushes very hard and brittle. Commutator after a short time became blackened, and scorched badly, necessitating truing up.

of copper. The laminations are sandwiched between copper-plates, and the whole held firmly together by means of two spring cheeks for about three-quarters of their length, the remainder of the brush being left free to allow of greater flexibility. Owing to the peculiar construction of this brush, each armature-coil when passing under the brush is cut in and cut out through resistance thus tending to reduce sparking. Another patent brush consists of sheets of anti-friction metal rolled to about the thickness of tissue-paper, folded, and formed under pressure to the size of the brush-holders. The metal of which these brushes are made has copper for its basis, and being very ductile, it possesses all the advantages of an anti-friction metal and is not effected by rubbing. With this type of brush practically no trimming is required, the corners being simply rounded off and the brush allowed to form its own bedding. It is essential to their good working that the commutator be perfectly true, and no lubricant of any kind whatever used on the commutator.

A great diversity of opinion exists among engineers as to whether anything of the nature of a lubricant should be used on commutators. Carbon brushes, if kept dry when running, have a tendency to produce a somewhat disagreeable screeching noise. The slightest trace of oil will usually stop this for a time, but the use of oil cannot be recommended, as, unless it is applied very sparingly, the oil carbonises and causes "flashing." Pads of oil, soaked rag, or waste are messy things to use, and are apt to cause trouble if left about open parts of running machinery. A substance which the writer has used for many years with success on machines fitted with carbon brushes is refined paraffin wax. For convenience in handling, the wax may be moulded in the form of round sticks. If rubbed lightly on the commutator occasionally, the wax should soon produce a good skin on the surface of the commutator. Sometimes carbon brushes may be improved by immersion for a few hours in melted paraffin wax. To keep copper brushes in good condition the foot of the brush should always be quite clean and flexible, and never allowed to get splayed out. A mixture used by the writer with excellent results on commutators with copper brushes is made up of the following ingredients: paraffin oil, five parts; olive oil, three parts; ammonia (spirits of hartshorn), two parts.

As mentioned before, the brushes should bear on the surface of the commutator with the least pressure consistent with sparkless commutation. The best pressure to use varies greatly with the many different types of brush-holders and brushes, and may be anything from a few ounces to as much as 6lb. or 8lb. Copper gauze brushes, if kept in good order, require about one-tenth of the pressure of that of carbon brushes. With the box or floating type of brush-holder the pressure on the brush is greater than in those of the hinged or swinging-arm type. In the former the brushes, being usually a good fit to prevent chattering, are apt to stick if dirt or grease is allowed to accumulate between the brush and box sides, hence it is well to see that the boxes be kept quite clean and smooth.

A weak point in nearly all types of brush-holders, and one which gives much trouble at times, is the bondings. The bonds frequently get broken owing to the vibration which they are subjected to when working, the break occurring usually close to the point of connection, particularly if the bonds have sweated connections. Many types of brush-holders depend almost entirely on the bonds for their efficient working. The writer has known of cases where defective bonds have been the cause of brushes and holders getting red hot. It is essential to the good working of any type of brush and holder that a continuous metallic path be provided for the passage of the current from the brush to the brush spindle or terminal, as moving joints cannot be depended upon; even if a close fit when new they sooner or later give trouble owing to the increased resistance which is set up at the joints as they become worn. Another weak point in nearly all holders of the hinged or swinging-arm type is that no provision is made for preventing the metal part of the holder from rubbing on the commutator when the brushes have been allowed to wear down too far. In the fixed box type this cannot occur owing to the brush-holder being rigidly fixed, the brush only being movable.

The writer has recently made a series of tests on various types and qualities of carbon brushes. The tests were carried out under everyday working conditions on machines ranging in size from 3 kw. to 100 kw. The results are shown in tabulated form in Table A. Type D is made by an American firm, the brushes being obtainable through a well-known English selling-house. Type A is manufactured in France, the firm having a direct agency in London. The writer concludes from the above that it pays in the long run to use a good quality of carbon brush, even though at first sight the prices may be rather high when compared with those of the poorer qualities. In the table, the brushes of machines (1), (2), (3), and (4) are all of the same size, quality A being the highest priced, B quality being about 40 per cent. cheaper. Machines (5), (6), and (7) have brushes all of the same size, D quality being the highest priced, qualities C and E being, respectively, 30 per cent. and 40 per cent. cheaper.

With some qualities of mica, particularly those of the "made-up" variety, the small particles of carbon and copper produced by wear become so firmly embedded in the mica that sometimes nothing short of turning or grinding up of the commutator will remove them. The mica between the

Digitized by Google

commutator bars should be tested occasionally for insulation. A handy method is to use a portable lamp-fitting, the lead being, preferably, of twin workshop-flexible. One wire is cut at a convenient point, to each end of which is soldered a short piece of brass wire (say, 10's gauge), slightly pointed. To use, the mica insulation is explored gradually over its entire length by means of the brass wires. Any bad places which may exist will be shown at once by the lighting of the lamp, the degree of brilliancy obtained being a rough indication as to the amount of carbon or copper deposit present.

Sometimes, when oil has been used on the commutators in such large quantities as to cause excessive sparking—the oil being carbonised by the great heat produced, due to the increased resistance between the brushes and the commutator—the insulation between the bars becomes charred so badly as to cause "flashing-over" from brush to brush, and where the brush-holders of opposite polarity are pitched close together, as is usually the case in modern multipolar machines resulting, perhaps, in the burning out of the armature, and destruction of the brushgear and brushes.

Brushes and gear should be examined daily, and any dirt, grease, etc, which may have collected, removed before the machine is put in service. For removing loose dirt a pair of bellows or an air syringe may be used with advantage, the nozzle of which, if of metal, should be insulated with a few layers of adhesive tape.

In conclusion, the writers' thanks are due to Messrs. Phillips' Commutator Grinder Company and to Messrs. The Edison and Swan United Electric Light Company, Limited, for their kindness in placing at his disposal the facilities for illustrating their respective commutator appliances described in the foregoing article.

KROONSTAD (ORANGE RIVER COLONY) ELECTRICITY SUPPLY.

The supply of electricity for lighting and power purposes is making great headway in South Africa just now. Nor is this surprising in a country of recent development, with little existing provision for artificial illumination except by crude and altogether inadequate methods. There is a gratifying lack of hesitancy in the choice of systems, when that choice rests between gas and electricity and insufficient room exists for both. Thus we see electricity supply not only making rapid headway in the large towns even against gas competition, but also extending in no halting fashion to the smaller settlements. Now to deal with a typical example—Kroonstad, to boot. The idea of lighting this town was initiated during the late war period, and after much discussion and many meetings, at which the promoters promised some extraordinary things relating to the cost of electric light compared with paraffin illumination, invitations were issued for schemes. Several firms responded, and Mr. Ferdinand Saunders, consulting engineer, of Johannesburg, was then called in to advise the Council as to the best of the schemes. His decision was in favour of one submitted by Messrs. Hubert Davies and Spain, of Johannesburg, who were thereupon awarded the contract, and on Dec. 6, 1904, the plant was handed over to the municipality.

The requirements of the case were very modest; little Kroonstad cannot make a stir in the electrical world like its big neighbour Johannesburg may be expected shortly to do, but it can be safely said that no plant in the country has been able to show more satisfactory results in such a short time. When the plant was taken over from the contractors eight months ago the load consisted of some 60 amperes, 40 of which were for street-lighting. To-day about 4,000 8-c.p. lamps or their equivalent are connected, and only last month the price charged per unit for lighting was reduced from 1s. to 9d., while efforts are being made to cultivate a day load by supplying current at 6d. per unit for power. During the half-year commencing January the undertaking has averaged a monthly profit of £20 after paying all running expenses, including £96 per month for depreciation.

The plant at present installed consists of two Willans two-crank compound engines of 100 h.p. each, direct coupled to two 60-kw. continuous-current generators by the Electric Construction Company. There is also a

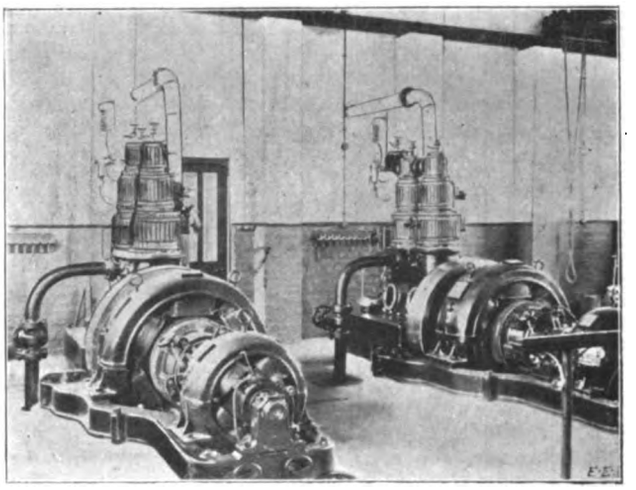

FIG. 1.—Engine-Room Plant, Kroonstad.

battery of 134 cells rated at 500 ampere-hours. This was supplied by Messrs. Pritchetts and Gold. The boosters for charging the battery are mounted on the same bed-

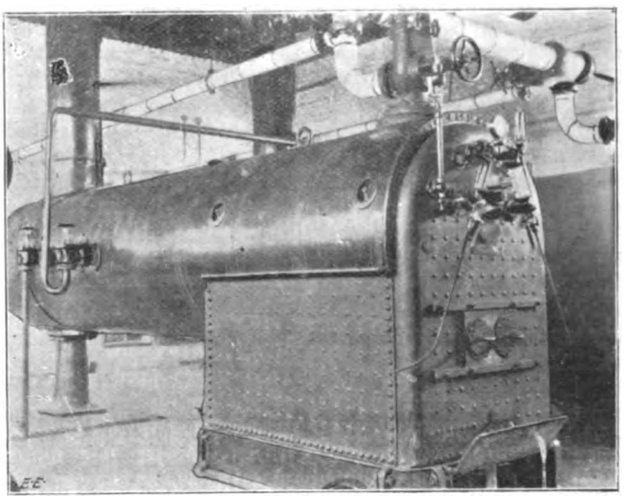

FIG. 2.—One of the Ruston and Proctor Loco.-Type Boilers, Kroonstad.

plate as the main generators. Fig 1 represents a general view of the engine-room. Steam is supplied by two Ruston and Proctor locomotive-type boilers (Fig. 2) of 40 n.h.p.

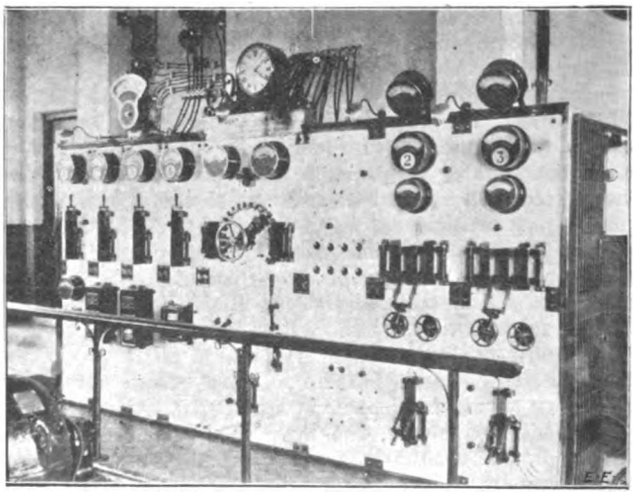

FIG. 3.—The Main Switchboard, Kroonstad.

each, at a working pressure of 140lb. The switchboard (Fig. 3) of white marble is divided into three generator, four feeder, and one battery regulator panels, while additional panels are provided for the necessary wattmeters

Digitized by Google

and recording instruments. So far as the outside work is concerned, it is worthy of note that the mains are run overhead, as shown in Fig. 4, and the town is divided into four sections, each having its own feeder. Nernst and ordinary incandescent lamps are used for street-lighting, and in connection with the former it may prove interesting, at a time when controversies are rife, to record the highly satisfactory results obtained, 75 per cent. of them having been in use for seven months or 1,100 hours without renewal.

Current is supplied to consumers at a pressure of 230 volts, meters by Chamberlain and Hookham being provided by the municipality at a monthly rental of 2s. 6d. Much difficulty has, however, been experienced in convincing consumers of the accuracy of their meters as the result of the extraordinary promises to which reference has been made in the foregoing. The load on the plant will receive a nice addition on completion of the pumping scheme which the Council have adopted in connection with the town's water supply. So far as municipal work is concerned this scheme is probably unique. It will consist of a motor-generator, installed in the present generating station, supplying current at 460 volts to a 45-h.p. motor direct coupled to a Mather and Platt three-stage high-lift centrifugal pump having a capacity of 20,000 gallons per hour and working against a 200ft. head. It is anticipated that

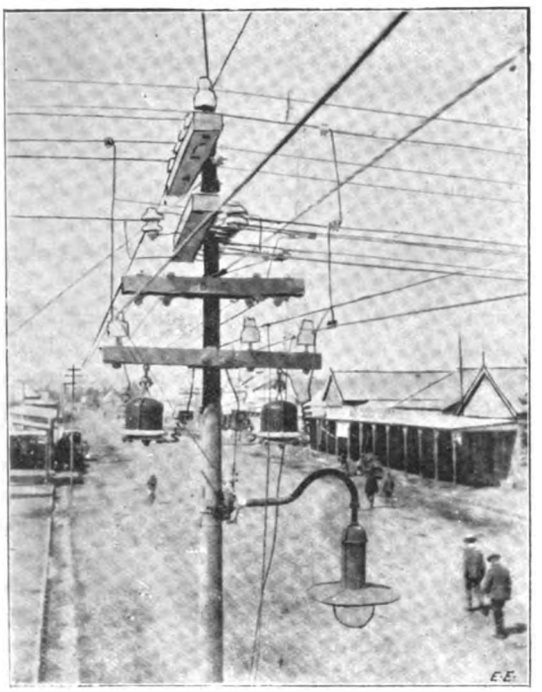

FIG. 4.—Overhead Mains, Kroonstad.

the cost of operating this plant will be considerably less than that of running the old steam-pumps.

We are indebted to Mr. Julian Vowles, the resident electrical engineer, for the particulars which have enabled us to prepare this article, also for the photographs from which the accompanying illustrations are reproduced. With regard to the latter, the excellence of the originals proves Mr. Vowles to be a skilful photographer. His abilities as an engineer and manager may be measured by the success which has favoured his charge in so short a time. In conclusion, we would heartily congratulate him upon that success.

THE FUSE FROM A PRACTICAL STANDPOINT.

(*Communicated.*)

The fuse question is of universal interest to all classes of users of electricity, from the employer of hundreds of motors in a factory down to the humble user of a few incandescent lamps. In view of the extremely important character of the device, it is a matter for surprise that a more determined effort has not been made to thoroughly standardise fuses *and* fuse carriers. It is quite useless to standardise fuse wire and strip and put it upon the market under such conditions that it will be used in connection with all sorts and conditions of fuse boxes and carriers. The mass of metal contained in the terminals of a fuse carrier exercises a great influence upon the carrying capacity of a fuse, inasmuch as the greater the mass of metal the more rapidly will the heat be conducted from the fuse and its carrying capacity be proportionately increased. It is, therefore, perfectly clear that the fuse and fuseholder should be tested together and sold as a standard piece of apparatus. Whatever the vagaries of fuses may be, the writer is perfectly convinced that it is upon the whole infinitely safer to use a carefully selected fuse upon all power and lighting circuits than to rely upon a circuit breaker only. Circuit breakers are useful and more easily and quickly replaced than a fuse, but they cannot be entirely relied upon, and a fuse should always be placed in series with a circuit breaker, the carrying capacity of the fuse being about 25 per cent. in excess of the current which will operate the circuit breaker.

The writer was once present when damage to the extent of £15,000 was done simply through the failure of a circuit breaker to act, and the circumstances of the case rendered it perfectly clear that practically no damage would have been done had a fuse been in series with the breaker. Such an object lesson as the above is calculated to leave an impression upon the mind which is not easily effaced, especially when accompanied by several other instances of a similar character, though upon a smaller scale.

In a power installation every motor should (whether provided with a breaker or not) be connected to the mains through a double-pole iron-clad fuse, careful attention being paid to the following points:

1. The fuse and fuse carrier must be of a tested and standardised type, carefully selected in accordance with the requirements of the particular motor it is to protect.

2. The fuse must be fitted into a removable insulated fuseholder, in order that it may not be necessary to handle live metal when replacing a fuse.

3. A supply of suitable fuses for replacement *must* always be kept in close proximity to the fuseholder, the best plan being to fix a small iron box containing the supply close to the fuse apparatus.

If the above simple precautions were honestly observed, the operation of fuses would be far more satisfactory, and there would be a marked falling off in the business of repairing burnt-out armatures.

ELECTRIC POWER FROM THE ANDES.

We notice that Mr. Emile Guarini, who has frequently contributed to our columns, has recently reported on the utilisation of the water stored in Lake Titicaca, in Peru. This lake is stated to be the highest in the world, its water-surface being no less than 12,644ft. above the sea-level. Here, as elsewhere in the Andes, there are enormous possibilities for the development of hydro-electric power, but the great difficulty is to find a commercial use for the power so obtained. Mr. Guarini, who has been commissioned by the Peruvian Government to look into the matter, advocates that in the present instance the water power should be used to drive electrically the southern railways of Peru. He estimates that the coal used on this line costs over £100,000 a year, and that the interest on the capital cost of the power plant would be much below this sum. Unfortunately, the railways in question would have to be electrified, and the cost of this would be no small matter. He also considers that there would be at least 6,000 h.p. to spare after the railways were electrified, and that this should be used for industrial purposes, for the lighting of the town, and for electric navigation. So far, figures have not reached us as to the fall which is easily obtainable from this lake, but from the map we see that the Andes lie between the lake and the sea-level—in fact, the waters from the lake find their way into the Amazon, and thence into the Atlantic, and not into the Pacific Ocean. The water power available all down the west coast of South America needs only a demand for power in order to form a most profitable field for electrical engineering.

TUNBRIDGE WELLS.

The farce of Tunbridge Wells still occupies the stage. The plot is simple, as is usual in farcical plays. A town with certain councillors plays with municipal trading—a strong and virulent opposition, aided by the paid services of anti-municipalist companies, sets to work to wreck all that is done municipally. The opposition makes a grand *coup* in one direction, and, having tasted blood, commences a vigorous attack on another point. In other words, the opposition, having succeeded in its telephonic effort, is now attacking the electric light undertaking, and the attack bids fair to succeed. We should have taken no part in this controversy but that the same old glaring mis-statements are made *re* depreciation and sinking funds. It is really painful to read the half-truths indulged in by the anti-municipal party, and though we in many cases prefer private enterprise, we have never hesitated to dub the tactics which use half-truths as the whole truth to be a disgrace to any controversialist. A writer in the *Courier* of Aug. 25 signs himself "An Accountant," deciding to use this *nom de plume* rather than give his name, because the latter "would not lend any particular weight to the discussion of this very important matter." That statement is about the only real truth in his letter. It is written to dispute the correctnes of Councillor Hicks, who previously wrote:

> "A trading company writes off every year depreciation, and has no sinking fund."
>
> "A municipal undertaking contributes every year to its sinking fund, and has no depreciation."
>
> "These two processes are identical. A sinking fund is a depreciation fund, and *vice versâ*."

"Accountant," with that arrogance so often associated with anonymity, says that "depreciation" and "sinking fund" "are absolutely and entirely different from each other." Well, no doubt he will maintain his assertion by quoting dictionary definitions of the word "identical." Mr. Hicks, of course, did not use the word identical in its strictly grammatical definition, but as the synonym of "equivalent." If "Accountant" is worth a moment consideration, it is because he, like others of his kind when driven into a corner, assumes the high and mighty in regard to rigid definition. Now, that will not do in this controversy, and we ask Mr. "Accountant," who poses as an expert, to point out, if he can, the practical difference in the following case: A borrows one thousand pounds of B, using that money as capital expenditure and repaying it periodically in equal instalments over a period of twenty-five years. A borrows one thousand pounds of B, C, D, etc., and expends it as capital, laying by periodically equal instalments over a period of twenty-five years. Never mind for a moment the asides of upkeep, etc. Assume the capital expenditure to be for ground rents for a period of twenty-five years, and that in both cases the renewal of the agreement can be made at the end of twenty-five years for another period of twenty-five, and so on. In the first case A has paid B the thousand pounds, and can borrow it again if he chooses and use it for the renewal of his agreement. In the second place, A holds the money for B, C, D, etc., and can use the money for a renewal of the agreement. Vary the second case slightly, and let B, C, D, etc., combine to furnish and use the capital, both in the first period of twenty-five years, and again in the second period, and so on. The cases are not identical, but the results are evidently equivalent, unless words and truth have lost their meaning. We have assumed a simple case without any of the asides which have to be brought in when dealing with such questions as municipal lighting or traction, but most of these asides can be treated just as

Digitized by Google

simply as the case we have taken. As regards the Tunbridge Wells municipal undertakings, it paid the opponents to first belittle and then buy the telephone system. Here the reasons were obvious, as the purchase checked the spread of municipal telephony and decrease of telephone rates elsewhere. In the case of the electric lighting undertaking no such widespread result would be obtained by the purchaser, who would get his profit solely from the consumers or by trading with the undertaking as a whole. The fact that someone is keen to buy is, perhaps, the best answer to the depreciating letter of "Accountant." If, however, the councillors still distrust their own capabilities as managers, they might consider resignation as an alternative to realisation of the assets of the town.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

MUNICIPAL TELEPHONY.

SIR,—There is little satisfaction in arguing over a dead issue or in disputing about politics. Municipal telephony is a dead issue, and during its active existence has been mainly politics. The inconsistency and inaccuracy of much of Mr. Bennett's letter published in your issue of Aug. 18 must be as apparent to you, Sir, and to your other readers interested in telephony as they are to me. The inconsistency of complaining of abuse and misrepresentation and in the same breadth abusing and misrepresenting everyone and everything else concerned, is too obvious to need comment.

I have given a good deal of study during a good deal of time to municipal telephony in this country, and I very much doubt whether, even if it had been taken up on right lines, it could have been made a success under the existing political, legal, and practical conditions. It is clear that the conditions were discouraging, as, in spite of all the efforts to promote municipal telephone systems, only five competitive systems exist. The watchful onlooker would probably say that enthusiastic municipal traders—and apparently all municipal traders are enthusiasts—do not as a rule look very carefully before they leap. The municipal telephone enthusiasts certainly did not give the subject the study it deserved. A study of the conditions under which municipal telephone enterprises were to be conducted would have sufficed to deter most business men. The business was to be a competitive one, conducted under a Government license of limited term and surrounded by all the rules, regulations, and restrictions that Government officials have the peculiar art of devising. In many cases there is a multiplicity of local authorities in one legally-defined telephone area, which creates obvious complications, and in all cases the competitor was already well established and thoroughly experienced in the business. Under these conditions it is small wonder that out of the 59 local authorities who looked into the telephone question after the Act of 1899 became law, only six established competitive systems.

But, apart altogether from the discouraging general conditions, the municipal telephone movement was dammed from the beginning by the adoption of bad rate schemes and inferior plant. If the municipalities which did take up telephony had gone into the business on right lines, had adopted modern plant and modern rate schemes, and had thoroughly studied the future development of the business, it is quite conceivable that they might have established themselves so successfully as to overcome the various legal difficulties, or to compel their modification.

The opportunity in Glasgow in 1900 was unique. Had the Glasgow municipal system been scientifically laid out with a modern telephone plant, designed for unlimited expansion, had a sound and business-like tariff been adopted, and had a thoroughly efficient telephone organisation been formed, the scheme in all probability would have been a success, and it would been a magnificent advertisement for municipal telephony. Everything was in favour of the Glasgow Corporation—free use of the streets, command of unlimited capital, powerful local influence, and friendly public opinion. But the whole scheme was foredoomed to failure from the moment it was decided to adopt obsolete engineering methods and an inflexible tariff. The call-wire plant, the armoured cable, the defective distribution scheme, and the rigid flat-rate tariff, have been cancers which have prevented all possibility of healthy growth.

The plain truth is that Mr. Bennett himself has been the worst enemy of municipal telephony. Long after general telephone experience had proved common battery methods to be the correct methods, he has clung to obsolete and relatively inefficient call-wire and magneto plant. Telephone cables buried solid have been tried and found wanting many years ago, but Mr. Bennett persists in the extensive use of armoured cable buried solid. The advantages of a flexible tariff are well understood by all telephone men, but Mr. Bennett clings to low flat rates, talks about "cheap telephones," and seems always to ignore that it is not "telephones" that a telephone exchange supplies, but *telephone service*, and that the requirements of consumers vary. The fundamental importance of studying future development and planning for it, the necessity (and the cost) of carrying much spare plant, and the dangers and difficulties of competition with a well-established system are not light considerations in the conduct of a telephone business. To Mr. Bennett they have been trifles light as air. I pointed out to Mr. Bennett, in Glasgow in 1897, the importance of studying development and spare plant. Mr. Bennett politely retorted that I was an American, come over to talk about "Tammany." Mr. Bennett has continued to ignore the eminently practical questions of development and spare capacity, and he has always prophesied that the competition would be a negligible factor.

It is because a difficult and highly technical business has been approached in this ill-considered and superficial manner, and because the practical work has been laid out on fundamentally unsound lines, that the existing municipal telephone systems have been failures. That they *have* been failures there is no question. They have been squarely beaten in the competition—notably so at Glasgow, where the trial of strength has lasted the longest. The financial results, on paper, show that in some cases both ends are made to meet. But even if all the working expenses were fairly debited and all the revenue credited were collectable, the financial results would still be wholly invalidated by the unsoundness of the capital accounts, for the capital accounts carry at its full cost plant which is worth very much less than the sums which have been spent on it. Sooner or later this would be bound to tell, as stern necessity compelled the rectification of the original mistakes. The symptoms are clearly evident at Glasgow, where the fundamental inefficiency of the call-wire system compelled the committee nearly two years ago to consider a general change in the system. They have been considering ever since, because an effective general change would mean practically a reconstruction of the plant and a very large expenditure which could not be faced. As a result of clinging to a defective system of working, the Corporation exchange has been overwhelmed in the competition, and is now simply "marking time." Is it not unreasonable to claim successful financial results when it is clear that the capital account—the backbone of the finances—is in a most unsound condition? It is equally unreasonable to claim that the municipal telephone business is generally successful, when the facts are that each competing municipal telephone system is in reality only a sort of side-show, not carrying more than a fraction of the real telephone load of the town and not able to obtain more than a fraction of the new business which offers. And none of the existing municipal systems is able to improve on these conditions, because none of them is designed, equipped, or organised to do a serious telephone business.

There is much more in the telephone business than was dreamed of in Mr. Bennett's philosophy when he started in to organise the municipal telephone systems. He has always taken the ground that he cannot learn anything in telephony from anybody else, and that is his misfortune—

Digitized by Google

and the misfortune of Glasgow, Hull, etc. Mr. Bennett's remarks on p. 235 on the new specification are characteristic of the manner in which he deals with technical and practical questions. He says, "In order to make the company's plant admissible for purchase, a much lower standard of efficiency than has prevailed with the corporations has been set up by means of a specification permitting of cheap and nasty methods." In the first sentence Mr. Bennett implies that the engineer-in-chief to the Post Office has been party to a conspiracy having for its object the purchase by the Post Office of inferior plant. Of course, that suggestion is too absurd for comment. In the next he states that the new specification admits of cheap and nasty work and a lower standard of efficiency than has prevailed with the corporations. On what *data* is such a sweeping assertion based? Apparently, Mr. Bennett's sole point is that it is modern practice to use in certain situations 600-pair cable, employing a 10lb. conductor, whereas the minimum conductor under the municipal specification is 12½lb. On this difference Mr. Bennett bases a most positive statement in the most general terms, in which he attacks both the good faith and the competence of the engineers of the Post Office and of the National Telephone Company, and ignores not only all the work that has been done of late years in the improvement of telephone cables and in the study of standards of transmission, but the very practical benefits that have resulted therefrom. When technical and practical questions are dealt with in this spirit by the chief exponent of municipal telephony, he unconsciously exposes the reasons for the technical and practical defects of municipal telephony.—Yours, etc.,

HERBERT LAWS WEBB

Westminster, Aug. 21, 1905.

[In conjunction with the above criticism of municipal telephony, which is largely a personal attack on Mr. Bennett, our readers should peruse the following extracts from a letter by Mr. D. M. Stevenson to the *Times*. The telephone question is now so far settled that further correspondence on the subject is unnecessary.—ED. *E. E.*]

THE TELEPHONE AGREEMENT.

Extracts from letter dated Aug. 19 to the Editor of "The Times."

SIR,—As chairman of the committee of representatives of the telephone-owning municipalities, which met in London from time to time during the sittings of the Select Committee on Post Office (Telephone Agreement), 1905, I should feel obliged by your allowing me to make some observations in the columns of the *Times* on your leading article of Aug. 10, and on the debate in the House of Commons of the 9th.

During its 10 weeks' sittings, the committee dealt with the question in the most painstaking and exhaustive manner. It made a number of recommendations, some of which the Postmaster-General adopted, but he declined to accept the one of most interest to the municipalities—namely, No. 28:

"While, therefore, we recommend that in the general public interest the House of Commons should not disapprove of the agreement, we think that the agreement with the modifications that we have proposed should not be allowed to become operative until a pledge has been given to the House that between now and January, 1912, nothing shall be done by the Government whereby the question of the future ownership and management of local telephone installations (as distinct from the ownership and management of trunk lines) may be prejudiced, and that, unless by a vote of the House it has otherwise been determined, the Post Office shall continue to grant licenses to municipalities on terms not more onerous in respect of royalties than the terms of the standard telephone license as revised in January, 1902."

Surely the only course open to Lord Stanley, in accordance with his pledge of May 22, was to let the agreement drop and commence *de novo* with a new agreement?

Dealing with the small number of municipalities owning telephone systems, the writer said Mr. Hanbury's Act empowering the granting of municipal telephone licenses was only passed in 1899 after five or six years' agitation. Glasgow, which got the first license, began operations in September, 1901, Portsmouth in 1902, Brighton and Swansea in 1903, and Hull in 1904. Municipal corporations are slow to move, and, with that prudence which the *Times* would be the first to commend, the bulk of them naturally preferred to wait the results of the experiments being made in Glasgow, etc., before embarking on the unknown sea of telephone enterprise. Long before there had been time to make trustworthy deductions from the experiences of the municipalities named, it emerged that the Post Office was determined to get complete possession, and with that object in view was endeavouring to arrange for the purchase of the National Company's undertaking in 1904. Mutually satisfactory terms could not be arranged, so negotiations for taking over the company's plant in 1911 were substituted, and ended in the agreement now under discussion.

If to all this be added the fact that paragraphs frequently appeared in the Press insinuating that the telephone-owning municipalities would have heavy losses on their plant when their licenses expired, because the licenses would not be renewed and the Post Office would only take over what plant it liked, your readers will have little difficulty in understanding why the Post Office was not besieged with applications for municipal licenses. Obviously it is only now that the municipal systems are beginning to show trustworthy financial results. These prove beyond doubt that in the telephone-owning municipalities telephone users, who are getting facilities incomparably better than they had formerly under the National Company, are only paying about half the rates paid to the company, and yet that the systems are self-supporting.

The London telephone service is admittedly much better since the Post Office entered the field, but I venture to say that Glasgow telephone users, accustomed as they have been for some time to the Corporation service, and to the enormously improved service that the National Company has been compelled to give in order to hold its own, would not tolerate for a week the delays and annoyances to which London subscribers are subjected, not to speak of the excessive rates charged there.

Mr. Austen Chamberlain said that no municipality which was not mad would start a telephone system in 1906 to terminate in 1911. I cannot agree with this view. If it were made clear that the future policy was to be, in the words of Mr. Benn, "the establishment of a useful State service worked in connection with the municipalities," many of them would undoubtedly apply for licenses nominally terminable in 1911, in the sure and certain hope that these would be renewed indefinitely. Moreover, it is inconceivable that if Parliament had stipulated that the agreement was only to become binding subject to the pledge embodied in Clause 28, the National Company would have refused to accept the modification. It was pointed out in the debate that their stock rose 33 per cent. as the result of the negotiations with the Post Office. The figures in the Stock Exchange lists show an even more remarkable appreciation, the deferred stock having been at 66¼ in 1903 and having touched 113¼ in 1905.

The directors of the company are far too able business men to have risked the wrecking of an agreement of such enormous advantage to their shareholders for the sake of preventing the establishment of the few additional municipal services which might have been in operation by 1911. In the same way they would certainly have yielded on the question of intercommunication and the abolition of terminals, had these been pressed for by the Postmaster-General in the interest of his licensees.

With regard to the policy of complete nationalisation, which the Post Office is endeavouring to force upon the country, with which I am sorry to find the *Times* agreeing, perhaps you will allow me to refer to an experience I had when inquiring into the question of telephone services some years ago in Germany, Denmark, Norway, and Sweden.

I found that for 100 miles south of the Danish frontier only the two large towns had telephones, whereas on the Danish side every village had its exchange, and each was connected to the Government trunk lines. The reason was obvious. Germany, centralised, had its uniform rate of £7. 10s., while the towns and villages on the Danish side were served by local companies at from £2. 4s. 5d. to £2. 10s. The city of Christiania has an admirable system covering a great area for £4. 8s. 10d. a year up to 6,000 calls, or £5 without limit. The famous Allmänna Company, of Stockholm, does still better, giving an unlimited service within a radius of 43 miles for £5. 11s. Think of it! On that basis Manchester subscribers would be able for £5. 11s. per annum to speak not only to all Manchester and Salford, but also, without extra charge, to all the towns within a circle round Manchester 86 miles in diameter—including Bolton, Liverpool, Preston, Oldham, Leeds, Bradford, Huddersfield, Halifax, and Sheffield—and all for a trifle more than half what is now paid for the Manchester area alone. Outside of London the maximum rate ought to be £6 or less, and the smaller towns and villages could be telephoned for half the money.

Surely, in view of facts like these, you will not persist in helping to get us swallowed up by a department which tells us frankly that it has no hope of reducing the £10 charge of the National Telephone Company? If it had its own way, and the Glasgow Corporation telephones were transferred to it to-morrow, the present subscribers would lose between now and 1913, when our license expires, some £250,000, not to speak of the loss to the thousands of citizens who would join the system between now and then if it remained under the control of the Corporation.

Digitized by Google

You ask, "Why should a municipality have a private telephone system any more than a private Post Office telegraph system?" and in the debate there was a tendency to accept Lord Stanley's assumption that the postal and telegraph systems leave nothing to be desired. Your commercial readers know how far this is contrary to fact. Thanks to the efforts of such men as Mr. Henniker Heaton and others in Parliament, improvements are taking place, but is it not pitiful in this country, which depends more than any other on facilities for rapid intercommunication, that we should be without the facilities for posting letters in all mail trains, which every Continental country has given to its citizens for many years, and that thousands of railway stations should be without public telegraph offices, whereas in the leading Continental countries a railway telegraph office is available to the public at every station?

In the matter of telephones the Post Office has still less to brag about. The trunk tariff is out of all proportion to the rates charged in other countries. For instance, from Glasgow to London the charge is 4s. 6d. for three minutes' conversation. In Sweden for the same service the charge would be 6½d., in Germany 1s. 6d. (which would cover half as far again), and in France 1s. 7d.

If this letter were not already too long, I should have liked to deal with the amazing statement of the Postmaster-General that "the instant the agreement became law there would be free intercommunication without charge throughout the whole of the United Kingdom"; the absolute futility of his stipulations regarding "maximum and minimum rates"; the illusory nature of "the prohibition of favour and preference," and various other points. But it may suffice to remind your readers that the Select Committee, which spent so much time studying the subject in all its bearings, came to the conclusion that the municipalities were substantially correct in their contentions. As this remains on record, notwithstanding the adverse votes of 187 hon. members on the 9th inst. (many of whom know nothing about the matter and had not even heard the discussion), the municipalities may confidently rely on satisfactory treatment from a new House of Commons.—I am,

D. M. STEVENSON.

LINE CALCULATION.

SIR,—In the correspondence of your issue of Aug. 25 "Duplicator" suggests certain corrections in "Newcastle's" answer to Question 795. The writer has, perhaps, used the words "load factor" rather laxly, for, as "Duplicator" points out, the $C^2 R$ loss is not proportional to the load factor used strictly; but in correcting this expression "Duplicator" falls into the error of saying that the $C^2 R$ loss is proportional to the square of the load factor. This statement is no more the case than the one he criticises.

There is no definite relation between the $C^2 R$ loss and the real load factor that can be used as "Duplicator" suggests. This loss is proportional to the *mean square of the varying currents*, not to *the square of the mean current*, as would have to be the case to make "Duplicator's" law true. The difference is a vital one. It is thus obvious that the annual loss can only be approximated to at the best, and what the writer meant to convey, as his figures show, was as follows: the full load $C^2 R$ loss is known, the variations of the current are absolutely unknown. Assume as a basis to work on that the total units lost in a year are 25 per cent. of what they would be if the full-load current were on the whole time. The whole solution is an approximate one, and, if one chooses, one can assume the average current to be, say, 50 per cent. of the maximum—the losses would, of course, then be proportional to the square of the current *if it were constant at 50 per cent. the whole time*, which, of course, it is not, or it would never transmit the full load required. This assumption, however, is not likely to be much more correct than any other one.

With regard to the resistance of 40 miles of No. 8 S.W.G., as "Duplicator" points out, this is not 59·5 ohms. Through some slip the No. 8 S.W.G. has been substituted for No. 6 S.W.G. If the curve of cost is referred to, it will be seen at once that No. 6 S.W.G. is the correct size to use, specially if the power required is likely to increase. The writer believes his formula for voltage drop to be correct, and would be glad to know how "Duplicator" derives the expression volts loss $= \frac{\text{total energy loss}}{1\frac{1}{2}\,C}$. His own is obtained thus:

Let V = virtual volts at generator end of line;
V_1 = virtual volts at distant end of line;
Let R = ohms resistance of one line;
C = current;

then $$C V \sqrt{3} \cos\theta = C V_1 \sqrt{3} \cos\theta + 3 C^2 R$$

$$(V - V_1) = \text{lost volts} = \frac{C R \sqrt{3}}{\cos\theta}$$

or with a power factor of 1 $= C R \sqrt{3}$

Yours, etc., NEWCASTLE.

ALTERNATE-CURRENT MACHINERY—INDUCTION ALTERNATORS.*

BY WM STANLEY, ASSISTED BY G FACCIOLI.

In the following pages it is proposed to discuss some of the elementary phenomena found while studying the performance of alternators excited by alternating currents. The alternators have their rotors and stators wound with distributed windings. The rotor circuits are supplied with very low frequency multiphase currents, as shown in Fig. 1. These currents produce a field, or fields, which move around the rotor at a speed proportional to the frequency of the magnetising or exciting source.

If the connection of the multiphase exciter is such as to produce a clockwise electromagnetic rotation of the field (rotor), the rotor structure of the alternator may then be mechanically revolved either in the same or in an opposite direction. Let n be the frequency of the exciting circuit and n_1 the frequency of mechanical rotation, then if the electromagnetic and mechanical rotations are in the same direction, the speed of the flux will be proportional to

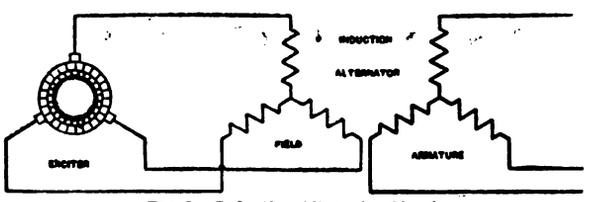

FIG. 1.—Induction Alternator Circuits.

$n_1 + n$; if they are in opposite direction to $n_1 - n$, and, as will be shown, these two relative arrangements produce very different phenomena. Call $n_1 + n$ or $n_1 - n = n_{11}$ = the frequency of the currents induced in the stator or armature conductors of the machine, evidently when $n = n_1$, $n_1 - n = 0$, and there is a stationary field in the space opposite to the stationary armature conductors; consequently no E.M.F. is induced. Suppose, however, that n is small compared to n_1—for example, let the exciting frequency $n = 1$ cycle, while the frequency of rotation $n_1 = 61$ cycles, then

$$n_1 - n = 60 \text{ cycles.}$$
$$n_1 + n = 62 \text{ cycles.}$$

Consider the first case for a moment. Suppose the stator or armature of the alternator is supplying current to an external circuit; then, if we have a clockwise rotation (revolutions per minute) of 61 cycles and a counter-clockwise electromagnetic rotation (exciting current) of one cycle, the effective field rotation is clockwise and 60 cycles; consequently, the armature (stator) currents are also of 60 cycles frequency. But these stator currents produce a field in the air gap of the machine, and this field revolves synchronously with the rotor induction, but not synchronously with the rotor conductors, for they (the conductors) are going faster—viz., at the rate of 61 cycles. They are, therefore, constantly overtaking the stator-produced field, and passing through it—that is to say, cutting it, and they, therefore, have E.M.F. induced in them of a frequency $= 61 - 60$ cycles $= 1 = n$, the exciting frequency; the final result being that an E.M.F. of the same frequency as that of the exciting current is produced in the rotor (field) conductors, by simply loading the alternator in the usual manner. This "stator-induced E.M.F." in the rotor conductors is evidently proportional to and in quadrature with the stator current. It is zero when the stator current is maximum, maximum when the stator

* Abstract from *Electrical Review* of New York of paper presented at the twenty-second annual convention of the American Institute of Electrical Engineers, Asheville, N.C., June 23, 1905.

Digitized by Google

current is zero, etc. It is of the utmost importance in the phenomena to be described, for if the rotor circuit be of low resistance (great time-constant) the "stator-induced E.M.F." in the rotor will produce a current (called "stator-induced current") approximately equal in value, nearly opposite in phase to the stator current, and, consequently, competent to neutralise the magnetomotive force of the armature or stator circuit and to destroy almost completely the magnetisation due to the stator winding. In such an alternator there should be, then, no armature reaction, no back magnetisation, no distortion of the field of the machine.

At first sight it would seem that these machines should give a constant E.M.F. at all loads; when excited at constant potential they do not do this, but they give, when properly designed, a gradually rising potential at power factor = 1 with a slight drop of potential for lower power

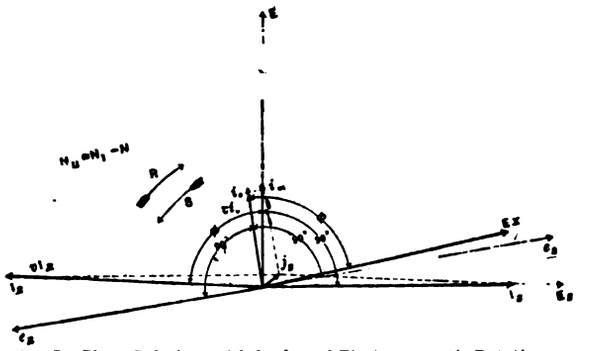

FIG. 2.—Phase Relations with Backward Electromagnetic Rotation.

factors down to power factor = 0. In Figs. 2 and 3, Mr. Faccioli has represented the phase relations of the E.M.F., currents, etc., when (Fig. 2) the effective frequency of the alternator is equal to the difference between the rotational and magnetising frequencies, and (Fig. 3) when it is equal to their sum. In the diagram here given the ratio of the rotor to the stator turns is assumed to be 1 : 1; the ohmic and inductive resistance of the exciter is zero—that is to say, the exciter is assumed to maintain a constant terminal potential.

In the case of Fig. 2 ($N_{11} = N_1 - N$) the flux of the alternator rotates in one direction regarding the rotor and in the opposite direction regarding the stator; therefore, the diagram is supposed to rotate in the direction R regarding the rotor, and in the direction S regarding the stator. v is the leakage coefficient of the rotor—that is, the ratio between the flux produced by the rotor which enters the

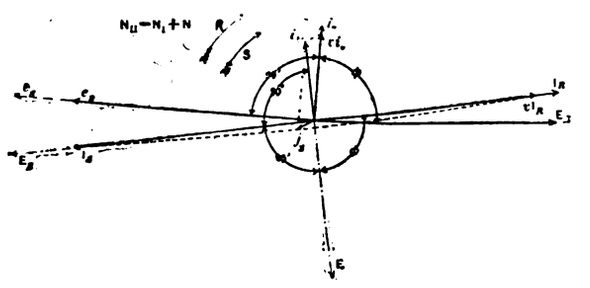

FIG. 3.—Phase Relations with Forward Electromagnetic Rotation.

stator and the total flux set up by the rotor. The leakage coefficient of the stator is assumed to be equal to the leakage coefficient of the rotor. E_x represents the E.M.F. of the exciter (low frequency) which is supplied to the terminals of the rotor, and is assumed as constant for any load of the machine. i_0 is the magnetising current of the machine at no load and lags behind E_x by the angle ϕ; ϕ being a function of the resistance of the rotor and the frequency of excitation. At no load the flux set up by i_0 will induce an E.M.F., e_R, of the terminals of the rotor; a part of the same flux proportional to $v\,i_0$, will induce an E.M.F., e_S, at the terminals of the stator.

Now consider the case in which the machine is loaded by the current I_S at power-factor unity. The current, I_S, of the stator (armature) induces at the terminals of the rotor (field) an E.M.F. in the direction of E, proportional to the frequency of excitation of the machine. The E.M.F., E, produces in the rotor a current, I_R, which lags behind E by the angle ϕ. I_S and $v\,I_R$ give a resultant, j_S, whose magnetomotive force is superimposed on the original magnetomotive force, $v\,i_0$, giving a resultant magnetomotive force, I_m, which is in quadrature with I_S. The E.M.F. of the stator is E_S in quadrature with i_m, and, therefore, in phase with I_S. In the case of Fig. 3, when ($N_{11} = N + N_1$), the diagram rotates in the same direction regarding the stator and the rotor. The same symbols represent the same quantities as in Fig. 2. In this case the E.M.F. e_S and e_R have the same direction, and the resultant magnetomotive force, j_S, has such direction as to decrease the original magnetisation, $v\,i_0$, of the machine; while in the case of Fig. 2, the magnetomotive force, j_S, due to the load currents, has the effect of increasing the no-load magnetisation of the machine. When, therefore, the generated frequency of the machine is equal to the difference of the frequency of rotation and the frequency of excitation, the magnetisation of the machine may be higher when

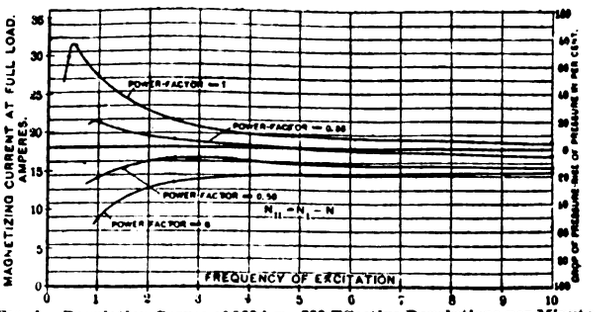

FIG. 4.—Regulation Curves of 100-kw., 900 Effective Revolutions per Minute, 60-Cycle Induction Generator.

loaded with non-inductive load than when running free; this result being principally due to the resistance of the rotor or field, which prevents the current I_R from lagging exactly 90deg. behind E, and, consequently, neutralising the magnetomotive force of I_S. On the other hand, the resistance of the rotor when the generated frequency is equal to the sum of the frequency of rotation and the frequency of excitation, has the effect of decreasing the magnetisation of the machine when loaded with non-inductive load. If the rotor of the machine had zero resistance and perfect mutual induction, then the rotor current, I_R, would lag exactly 90deg. from its E.M.F. in both Fig. 2 and Fig. 3, and would be exactly equal and opposite to the stator current, I_S. There would

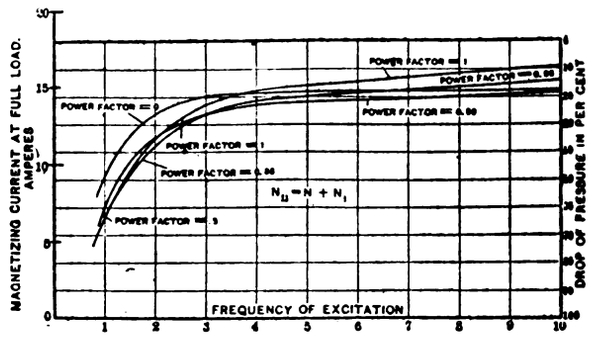

FIG. 5.—Regulation Curves of 100-kw., 900 Effective Revolutions per Minute, 60-Cycle Induction Generator.

be no resultant magnetomotive force due to the load, and, therefore, j_S would be equal to zero, and the machine would have constant E.M.F. at any load and at any power factor. It then appears that if a machine of this type—that is, a machine with almost perfect mutual induction and very low resistance—could be built, there would be very little difference in its regulation when excited by forward and backward running fields. The principal difference would consist in the fact that with a forward running excitation the exciter would supply energy to the alternator in proportion to the ratio of the exciting to the generated frequency, while with the backward running excitation the exciter delivers no energy to the alternator, but receives energy from it.

Fig. 4 shows the regulation of the induction alternator at different frequencies of excitation. The curves belong to a 100-kw., eight-pole, 60-cycle, 900 effective revolutions per minute machine built by the Crocker-Wheeler

Digitized by Google

Company for experimental purposes. Figs. 2 and 3 refer to the same machine. The curves of Fig. 4 are in perfect accord with the actual tests made on the machine, the results of which are given later on. This figure shows that for each machine—that is, for each combination of resistance and leakage in any machine—there is a certain frequency of excitation below which trifling changes in the constants of the alternator produce great changes in its potential characteristics. For small high-frequency machines an exciting frequency of about five cycles may be required, while on large machines in which the resistance and leakage may be relatively lower, the exciting frequency may be as low as one cycle. In a similar way it is possible to study the influence of the variations in the exciting frequency in the case of the forward rotation of the field. Fig. 5 gives the regulation of the same 100-kw. alternator at different power factors for different frequencies of the field. The curves in Fig. 5 show that, in the case of forward rotation of the field, the potential of the alternator will drop at any power factor, due to the effect of the resistance and leakage, but the difference in regulation between power-factor unity and lower power factor is very small in comparison with the results obtainable with the alternators of standard type. (The phenomena in this machine are magnified by the high resistance of the rotor.)

The variation of the air-gap in these machines has a peculiar influence on their regulation. Doubling the air-gap of the same machine has very little effect on its regulation at the frequency which is used for its excitation (about five cycles). This is due to the fact that any increase in the air-gap involves an increase in the no-load

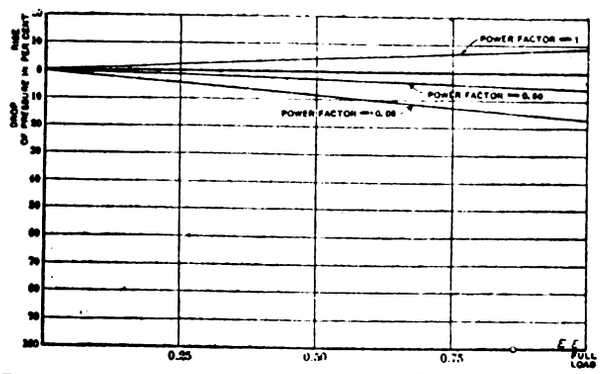

FIG. 6.—Regulation Curves of 100-kw., 900 Effective Revolutions per Minute, 60-Cycle Induction Generator.

magnetising current of the machine and an increase of the leakage coefficient, v, and these two phenomena have conflicting influences on the regulation of the alternator. When, however, the leakage of the machine is comparatively low, as in the case of high-speed alternators with a small number of poles, and the no-load magnetising current is high (large air-gap), then something is gained in regulation by increasing the length of the air-gap. For instance, this is the case with turbine alternators where a large air-gap is required for mechanical reasons.

Considering now the phenomena of the system, the following general conditions are found: the current in the exciting circuit is composed of two parts or components—first, that due to the exciter E.M.F., which is the no-load magnetising current; secondly, the current due to the E.M.F. generated in the field (rotor) conductors by the stator load current. The first of these, the no-load magnetising current (volt-amperes), is for any given capacity of the alternator inversely proportional to its speed—that is, is proportional to the number of poles of the alternator for any given generated frequency, or is proportional to the frequency of the alternator driven at constant speed. This magnetising apparent energy is therefore small with high-speed machines of given frequency, and small with low-frequency machines of given speed; consequently, it is smallest in low-frequency turbine alternators and is larger in slow-speed direct-connected high-frequency machines. It is to be remembered, however, that the magnetising current is only a fractional part of the full-load current in the exciting circuit; therefore it is not necessarily a limiting condition, and does not determine the size of the exciter.

The second component of the exciting current is the superimposed component, and is approximately equal in total amperes to the armature current of the alternator. The E.M.F. of the exciter is proportional to the E.M.F. of the alternator multiplied by the ratio of the exciting to the generated frequency. The two components of the exciting current (the magnetising and superimposed) have the following phase relations. When the alternator is delivering current at power-factor unity, the magnetising and superimposed components are nearly in quadrature; when the alternator delivers current at power-factor zero, the components are nearly in phase. If we call M the no-load magnetising volt-amperes of the exciter, N_1 the frequency of excitation, N_{11} the generated frequency of the alternator, W the capacity of the alternator in kilovolt-amperes, we have the size of the exciter approximately proportional to

$$\sqrt{M^1 + W^2 \frac{N^2_1}{N^2_{11}} + 2\,M\,W \frac{N_1}{N_{11}} \sin\phi};$$

ϕ being the maximum angle of lag of the current that the alternator is called upon to deliver. Thus, if the alternator is a 100-kw. 25-cycle machine excited at a frequency of 2·5 cycles, and the no-load magnetising volt-amperes are five kilovolt-amperes, and if the alternator is called upon to deliver its full-load current at power factor 0·5, the size of the exciter is:

$$\sqrt{5^2 + \left(100\,\frac{2{\cdot}5}{25}\right)^2 + 2 \times 5 \times 100 \frac{2{\cdot}5}{25} \times 0{\cdot}86} = 14{\cdot}5 \text{ kilovolt-amperes.}$$

It will then be seen that the exciter is called upon to carry a current practically equal in total amperes

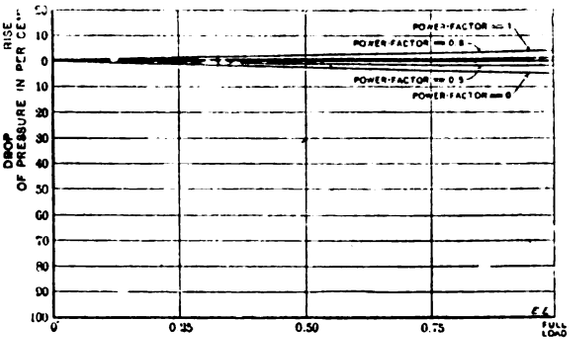

FIG. 7.—Regulation Curves of 1,500-kw., 1,500 Effective Revolutions per Minute, 25-Cycle Induction Turbine Alternator.

to the load current of the alternator, the apparent energy of which is dependent on the frequency of excitation; consequently, the aim of the engineer is to so design his machines that they will require the minimum exciting frequency.

Fig. 6 shows the regulation curves obtained from tests of the 100-kw., eight-pole, 60-cycle, 900 effective revolutions per minute alternator above mentioned, as a function of the load of the machine when its field is excited by five-cycle current at constant potential (backward rotating field). For full load of alternator at power factor 0·8 the size of the exciter is 13 kilovolt-amperes, or 13 per cent. of the size of the alternator. The curves agree very closely with the calculated characteristics of the alternator. Fig. 7 refers to a 1,500-kw., 25-cycle, 1,500 effective revolutions per minute turbine alternator. The frequency of excitation is 0·75 cycle, and the exciter at full load of the alternator power factor 0·8, has a capacity of 95 kilovolt-amperes—that is, 6·5 per cent. of the size of the alternator. Fig. 8 gives the exciting watts for different loads of the 100-kw., 60-cycle, eight-pole alternator (at unity and lower power factors). As shown by these curves, the energy delivered to the alternator at no load is small and positive. As the alternator load increases the current in the rotor magnetising circuit increases, but the watts fall to zero and reverse—that is, the current in the rotor-exciter circuit lags until it exceeds 90deg. behind the exciter E.M.F. It therefore flows through the exciter against the exciter's E.M.F., just as a current delivered by a generator flows through a motor circuit against the counter E.M.F. of the motor.

The all-important factor in the design of induction alternators is, then, the excitation. At first sight the designing of an efficient and economical exciter to deliver multiphase

Digitized by Google

exciting currents of five cycles or lower frequency would appear to be an almost hopeless undertaking, for if an exciter of, say, three-cycle frequency and 50 kilovolt-amperes is necessary to furnish the field and controlling current for a 500-kw. alternator, working on old lines, we should be compelled to design a two-pole machine of 180 r.p.m. to deliver 50 kilovolt-amperes at power-factor zero to unity power factor. The manufacture of such a machine would ruin any going concern. We are therefore compelled: (1) to find such a method of generating the exciting currents as will permit the use of normal speeds and consequent reduction of size of the exciter—that is, the exciters must be designed to give low frequencies at high speed; (2) to produce the desired potential gradient on the alternator, we must so design the exciter that it will have a characteristic complementary to that of the natural characteristic of the alternator it excites. These are severe conditions to impose upon any machine, but they have been met in a novel manner in the machine about to be described. It is evident that if the field of an ordinary direct-current machine is slowly alternated, corresponding alternations in the E M F. of the armature will occur. Such a machine could evidently be driven at any speed and would give alternating current through its commutator and brushes corresponding in frequency to the frequency of its field, but it could furnish single-phase currents only. It is evident also that two such machines could be coupled on the same shaft, each

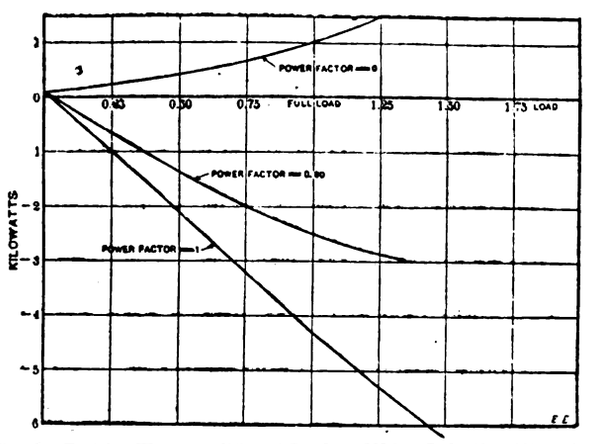

FIG. 8.—Exciting Watts for different Loads of 100-kw. Induction Alternator.

machine having its field excited by low-frequency and phase-differing currents; and such an arrangement would generate from the two armatures two phase-differing currents, whose frequency is independent of the speed of rotation. If, now, these two fields are combined in one machine—that is, if the field is a Ferraris or rotating field instead of a simple periodic field—it is evident that a single armature with a simple commutator and four brushes placed in quadrature around the commutator will deliver two sets of alternating currents, differing in phase by the angle of the brush displacement, and at the same frequency as the rotating field, and that the figuring of the generated currents will be independent of the speed of rotation. Such an arrangement might be a machine in which the stator consists of a four-pole structure having energising coils diametrically located on opposite poles and connected to a two-phase source of excitation, while the armature and commutator deliver two-phase currents to external circuits. But this arrangement presupposes and employs a third element to furnish the original exciting current of the exciter.

In order to make the exciter self-exciting and self-contained, and to reduce the apparatus to the simplest terms, the following scheme for excitation has been devised (Fig. 9). A pair of brushes corresponding to those of an ordinary generator is connected to a field coil, so located with reference to these brushes that the flux it produces will be displaced by a predetermined angle dependent upon the number of phases desired. Thus for a two-phase machine a pair of brushes is connected to a field coil so located as to produce a flux, by means of which and by rotation an E.M.F. is generated upon the other pair of brushes, while the second pair of brushes is connected to a coil so located as to produce a flux that will generate an E.M.F. on the first pair of brushes. This is shown in Fig. 9, which illustrates the connection and operation of self-excitation by means of two and three phase currents. Let the residual magnetism of the machine be as shown in the diagram. Then, on rotating the armature, an E.M F. will be developed on brushes 2—4. These brushes are connected to the field winding at X—X¹ instead of at Y—Y¹, as is usual in exciting continuous-current machines, consequently a current will flow, say, from X through a—a to X¹, producing a flux through the armature at 90deg. to the residual magnetism. A resultant field will, therefore, lie between the points Y—X and Y¹—X¹, but this field will generate an E.M.F. on brushes 1—3, and these brushes will deliver a current through Y—a—a—Y_1 in such a direction as first to oppose the residual magnetism and afterward reverse its direction. At the instant that the residual magnetism is zero the only field operating in the machine is that due to the currents from the brushes 2—4; subsequently this field combines with the vertical reversed field to brushes Y—Y_1, producing a resultant with polar line between X—Y¹. These operations being cyclic, they recur at periodic intervals, and the phenomena become continuous. At the resistance of the energising circuit a—a is low in comparison with its inductance, the currents delivered from each pair of brushes lag nearly 90deg. behind the E M.F.'s, and, therefore, little energy is wasted in field excitation. This process of excitation presents many curious and interesting features. If, for example, one of the magnetising circuits, such as X, be disconnected from the armature, the field immediately dies out, even if there is no current in circuit at the instant of the breaking.

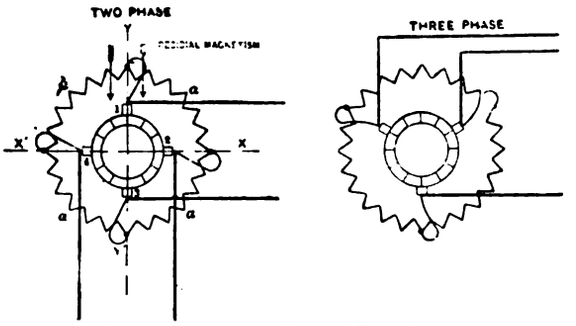

FIG. 9.—Self-Excitation by Two and Three Phase Exciters.

The approximate calculation of the frequency of self-excitation as given by Mr. Faccioli will be found by considering for a moment the physical phenomena that occur. Assume the speed of rotation of the armature to be n_1; let the machine be a single magnetic circuit machine with X conductors in the armature and Y conductors on the stator. A moment's consideration of the laws of induction will show that the direction of the current delivered by the armature to the field must be such as to produce a field rotating in the same direction as the rotation of the armature. Let the frequency of this rotating field be N, then evidently the effective frequency of the armature conductors will be:

$$N_1 - N = N_{11}.$$

We therefore have X armature conductors cut by the flux of the machine at frequency n_{11}, and Y conductors of the field cut by the same flux at frequency N; therefore there will be two E.M.F.'s, one on the rotor and one on the stator for each magnetising circuit, and, as is evident, the condition of equilibrium of current flow will be obtained when these two E.M F.'s are equal and opposite to each other. This condition of equilibrium will always be fulfilled for a certain frequency of self-excitation; such, in fact, as will make

$$X N_{11} = Y N.$$

But $$N_{11} = N_1 - N,$$

so $$Y N = (X N_1 - N),$$

and $$N = N_1 \frac{X}{X+Y}.$$

That is, the frequency of self-excitation will be equal to the frequency of rotation times the turns on the rotor divided by the sum of the turns on the rotor and stator. By

Digitized by Google

this formula we can easily determine the winding of a machine for a given frequency of self-excitation; for instance, in the case of a two-pole machine in which the speed of rotation is 900 r.p.m. (15 cycles) the number of armature conductors is 200 and the frequency of self-excitation desired is three cycles, we find that the number of turns required on the stator is

$$\frac{200\,(15-3)}{3}=800.$$

Evidently these results are only strictly true when the resistance and leakage of the machine are zero, or not considered, as these quantities have a slightly modifying effect. When the windings are similarly disposed in rotor and stator it is not necessary to take into consideration the winding distribution coefficients, but the proper coefficients should be employed when the stator has salient poles. This type of machine satisfies, therefore, the first condition laid down as necessary for a commercial exciter, for it produces low-frequency multiphase currents at normal speeds. It also fulfils the second condition—that it should deliver zero and negative power-factor currents at constant or rising potential with much greater exactness than the ordinary type of alternator; for the reason that the armature reaction of a machine of this type may be made practically zero, because the field of the machine progresses in the same direction as the rotation of the armature, and consequently tends to maintain the E.M.F. at low power-factor loads, and because it may be compensated to give a positive potential gradient.

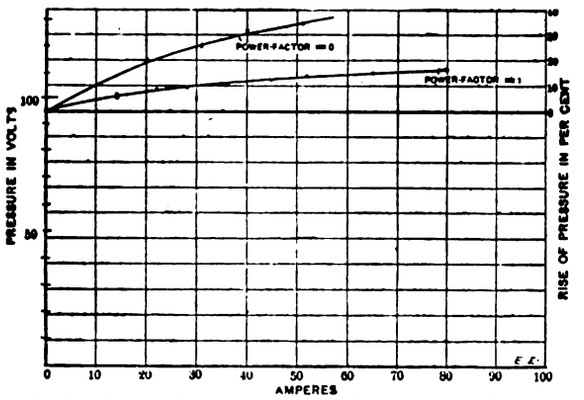

FIG. 10.—Voltage Characteristics of a 10-Kilovolt-Ampere Exciter.

Fig. 10 gives the voltage characteristics of a 10-kilovolt-ampere exciter as a function of the amperes of load for power factor = 1 and power factor = 0. The frequency of self-excitation of this machine, when run at 900 r.p.m., is five cycles. An examination of the characteristic curves of the induction alternator ($n_1 - n$) type (Fig. 6) shows that the potential gradient of these machines is positive for load currents of unity power factor, zero for load currents of (about) power factor = 0·8, and negative for currents of power factor = 0. If, therefore, the exciter is given such a characteristic that the E.M.F. of the exciter will be slightly lower when the alternator is full loaded with power factor = 1 currents, and slightly higher when the alternator is delivering low power-factor currents, the potential of the alternator may be maintained practically constant for any variation in load or power factor. It is to be remembered that the exciter when used with ($n_1 - n$) type of alternator is never called upon to furnish power-factor unity currents, but to receive them, and that the magnetising reaction of such currents upon the exciter field is exactly the reverse of that found when the power-factor unity currents are delivered; therefore, the exciter should be so designed when used with this machine as to give an increase of potential when delivering power-factor unity currents (that it may have a negative potential gradient when receiving them), as well as a slight increase of potential when delivering power-factor zero currents.

Oxford.—Mr. Worby Beaumont, who has been reporting on the traffic facilities of Oxford, has advised that the tramways should not be electrified, but that a motor omnibus service should be started. The Corporation called in two experts, and we expect that Mr. Stephen Sellon's advice will conflict with the above.

TRADE NOTICES AND NOVELTIES.

Automatic Devices.

From the Union Electric Company, Limited, 151, Queen Victoria-street, London, E.C., we have received an interesting list of their automatic time integrating devices, of which we have selected two for special reference herewith. Where

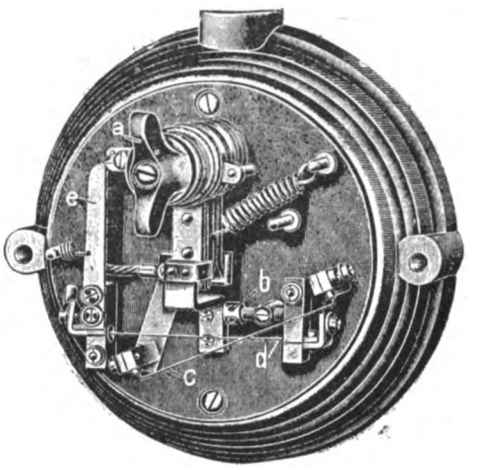

FIG. 1.—Maximum Switch.

current is supplied at time rates for small motor, arc, or incandescent lamp circuits, it is desirable to have a switch which automatically opens the circuit when the maximum agreed current is exceeded. It is claimed that the maximum switch (Fig. 1) does this both safely and effectively without adding materially to the cost of the installation. A cover of either stout insulating material, zinc or iron, encloses the mechanism, which consists of a hand switch operated from outside against a spring. The switch blade is held in the contact position by a detent operated by a control wire through which the main current flows. Excess of current lengthens this control wire, *d*, thereby permitting the lever, *e*, to move sufficiently to release the detent holding the switch. By means of the screw, *b*, the regulation can be altered to about 20 per cent. + or −. The device Fig. 2 is designed for cases where it is desired to switch on or off, at a distance, one or more circuits of considerable ampere capacity by means of either a high or low voltage operating circuit. It consists of a powerful switch with quick make and break, controlled by a spring mechanism and worked by a small current in a fine-wire operating circuit. This operating circuit can be closed by either the firm's contact clock or by one or more of their contact makers coupled in parallel. There are two finishes, one in an oak case and the other in a metal watertight case. For the rest it must

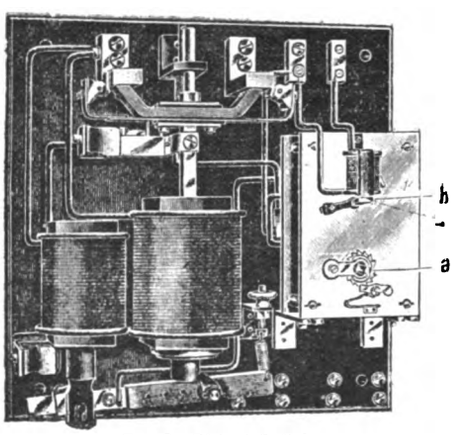

FIG 2.—Distant Switch.

suffice to say that the devices described in the list under notice embody many new principles in the way of determining the charges for the supply of current and controlling the current in use.

B.T.H. Motors and Generators.

We are indebted to the British Thomson-Houston Company, Limited, Rugby, for particulars of a new line of continuous-current motors and generators which they are introducing to the trade. These machines will be known as the "D B" and "M P" types respectively, the first-mentioned ranging in capacity from 25 h.p. to 70 h.p. as motors and from 20 kw. to 50 kw. as generators, while the "M P" type will be made in standard sizes for capacities from 70 h.p. to 100 h.p. as motors and 50 kw. to 100 kw. as generators. The "D B" motors and generators are supplied either without covers, with perforated

Digitized by Google

covers, or with solid covers. The ventilated machines are fitted with removable perforated covers, and the totally enclosed machines with removable solid covers, and although well protected, the brushes, commutator, and bearings are made very easy of access. On the other hand, the "M P" machines are supplied in "open" type only, and are not suitable for enclosure. In both "D B" and "M P" machines the frame, which is also the magnet yoke, is of cast iron and circular in form. The "D B" machines are provided with end shields (see Fig. 1), which afford protection and support the bearings. The commutator end shield is in the form of a commutator box with

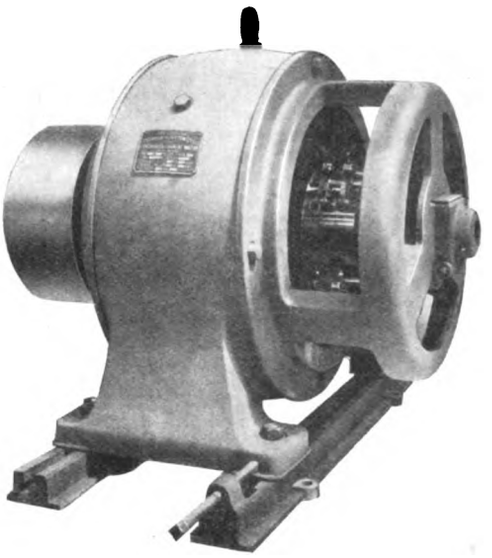

FIG. 1.—"DB" Protected Motor.

hand holes, and the pulley end shield is of dished form with three openings. The hand holes give access to the commutator and brushes, and allow of general inspection of the moving parts, at the same time permitting a thorough circulation of air through the motor. The "M P" machines have no end shields, the bearings and frame being supported on a common bed-plate (see Fig. 2). The frame and bearings, it will be seen, are divided in a horizontal plane, permitting easy removal of the armature. In both types the field coils are held in position by means of the projecting pole tips, and can be readily removed. The magnet cores are of laminated iron punchings. By turning

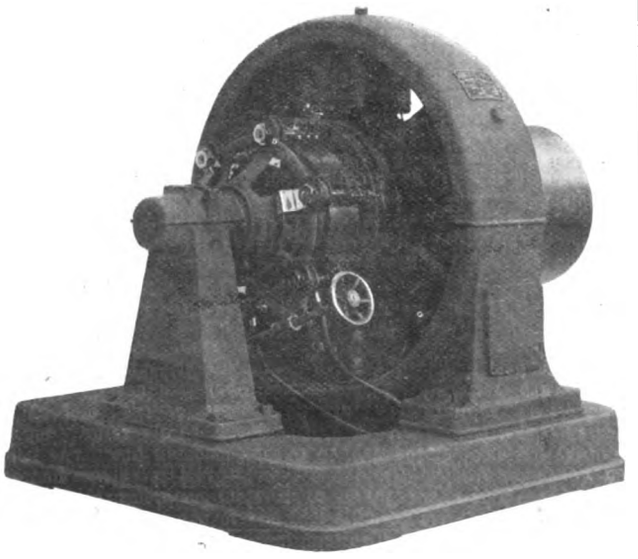

FIG. 2.—"MP" Motor.

the end shields 90deg. or 180deg., the "D B" motors may be arranged for operating on wall or ceiling. The bearings of the "M P" machines are of the self-aligning type. In both cases the bearings are lubricated automatically by oil wells and rings, and are provided with gauges. Further, in both types the armature (Fig. 3) is drum wound, and consisted of a laminated core with slots in which the form-wound coils are embedded. The core is built up on a spider keyed to the shaft. The armature is so constructed as to permit a thorough circulation of air through core, windings, and commutator. The commutator is mounted on an extended sleeve on the armature spider, so that the shaft may be removed without interfering with the windings of the armature. The commutator shell is provided with air ducts running parallel to the shaft to allow of air passing into the armature from each end. The brush-holders of these machines contain a coil spring, which exerts a uniform pressure throughout the wearing length of the brush. With this type of pressure spring there is no appreciable friction which would tend to change the pressure on the brush after it is properly adjusted. An adjustable lever in the rear of the holder enables the pressure to be regulated throughout the whole life of the brush. The brushes are of carbon with pigtail connections, ensuring perfect electrical connection independent of the contact between the brush and holder. Any brush can be removed whilst the machine is in operation without disturbing the others and without removing the holder from the stud. The protected "D B" machines and type "M P" motors and generators will run for six hours at rated load and voltage with a temperature rise above the surrounding air as measured by thermometer on any accessible part of the machine not exceeding 40deg. C. (72deg. F.), the temperature of the air during

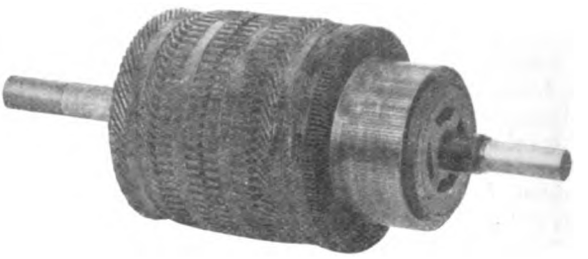

FIG. 3.—Armature for "DB" or "MP" Machines.

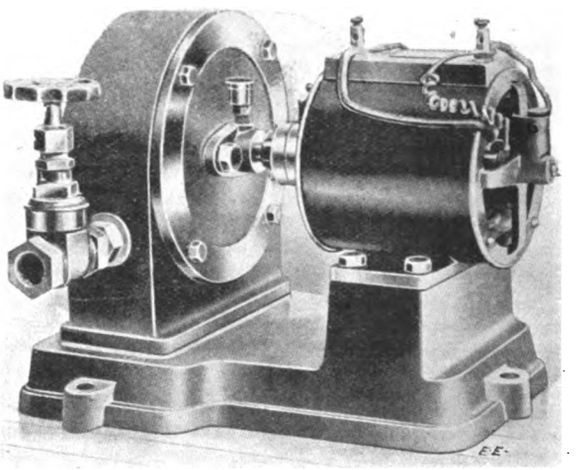
test not exceeding 25deg. C. (77deg. F.). Both "D B" and "M P" machines will operate without movement of the brushes and without sparking at the commutator from no load to 10 per cent. overload, and with overloads of 25 per cent. for one hour and 50 per cent. momentarily without injurious heating or sparking. Standard motors, either shunt or compound, are wound for circuits of 110 to 120, 220 to 240, 440 to 480, and 500 to 525 volts respectively. The "D B" and "M P" generators, it may be added, are also supplied both shunt and compound wound.

Combined Water-Motor and Dynamo for Charging Accumulators.

Accompanying is an illustration of a Pitman "Hector" water-motor coupled direct to a dynamo, the whole being mounted on one cast-iron bedplate. The "Hector" water-motor consists of a cast-iron body fitted with three adjustable nozzle tips of phosphor-bronze, the jet of water striking a small Pelton water-wheel, and exhausting at the bottom of the case by way of a small pipe, not shown in the illustration. The Pelton wheel is



Hector Water-Motor Combination.

a steel plate, fitted with phosphor-bronze buckets of special improved shape, and gives 85 per cent. efficiency with any pressure of water over 40lb. per square inch. With lower pressures a belt drive is necessary to get the requisite speed. The dynamo is of a special iron-clad type, wound to give any voltage desired, and the bearings are of great length, the whole apparatus being of thoroughly up-to-date and substantial construction. A ½in. bore pipe off the ordinary town's main is all that is required to drive it, and as the nozzles are extremely small (1/16in., ⅛in., and 5/32in.), and only one used at a time, the water consumed is negligible. The combination is silent running, and involves no risk of fire where motorcars and petrol are about. By means of the full-way regulating valve provided

Digitized by Google

the speed of the motor can be reguiated as desired, and the machine may be left running without attention if fitted with a cut-out. We are indebted for the above particulars to the manufacturer, Mr. Percy Pitman, of Bosbury, Ledbury, where we understand similar combinations to that described above may be seen arranged for charging motorcar accumulators and for house lighting, with only 6ft. fall of water as motive power.

Network Ohmmeter

To meet the want of a rapid and reliable means of testing the joint insulation resistance of a complete three-wire network, without interrupting the supply, the ohmmeter shown in Fig. 1

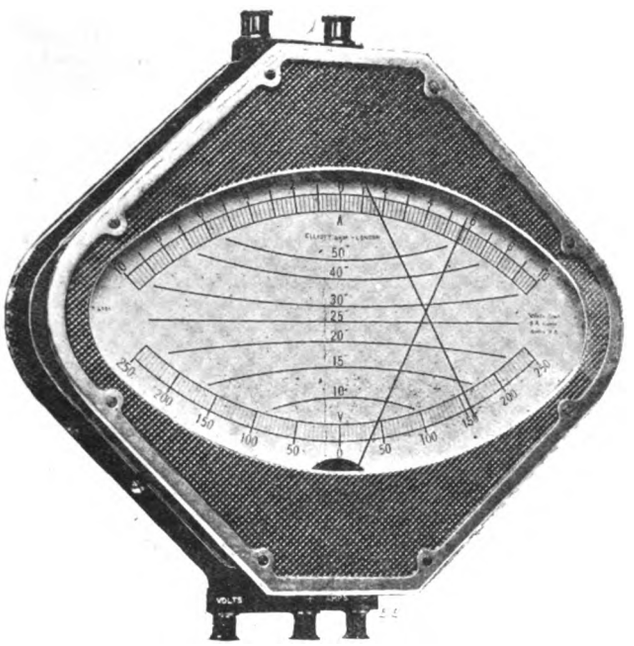


FIG. 1.—Network Ohmmeter.

herewith has been devised by Mr. Groves. The formula employed is $F = \frac{V_1 - V_2}{C} = \frac{V_1}{C} - R$; where F = joint insulation resistance in ohms; V_1 = potential between neutral and earth when there is no artificial earth connection; V_2 = potential between neutral and earth when an artificial earth connection

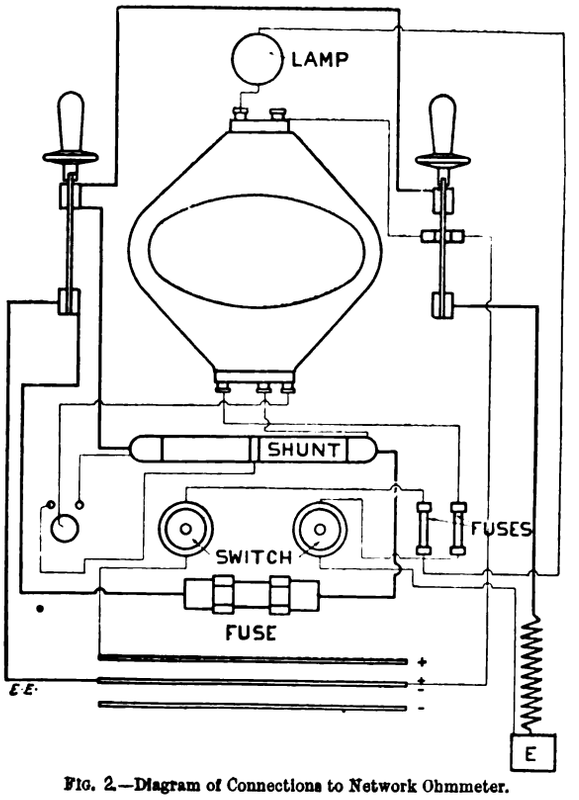

FIG. 2.—Diagram of Connections to Network Ohmmeter.

is made; C = current passing through the earth connection; R = resistance of artificial earth connection. R, being of low resistance, not exceeding, say, two ohms, may be ignored, and $F = \frac{V_1}{C}$. The instrument consists of a combined ammeter and voltmeter. The pointers move in parallel planes and overlap, the point of intersection of the pointers giving the required readings, F, on the scale. Fig. 2 shows a method of connecting up the instrument. The ammeter shunt of the ohmmeter is short-circuited by a switch, which is only opened when the test is being made, and when the recording ammeter shows a reading not exceeding the limits of the ampere scale of the ohmmeter. This switch is first opened, and then the operating switch. As the required deflection of the ammeter and voltmeter movements are obtained under different conditions, the operating switch is provided with an attachment which locks the ammeter pointer while the voltmeter pointer deflects. For the above particulars we are indebted to the makers of the instrument, Messrs. Elliott Bros., Century Works, Lewisham, S.E., who have also sent us an illustrated pamphlet describing their "Century" portable mains testing set. This set has been designed, we are told, with a view to provide the mains superintendent and cable engineer with an instrument that will cover the whole range of testing likely to be met with in laying and maintenance of underground cables. We must refer the reader to the pamphlet in question for details.

Catalogues, etc., Received.

LUBRICATION AND LUBRICATORS.—From Messrs. Rimington Bros., Carlisle, and 63, Queen Victoria-street, London, E.C., comes a catalogue dealing with lubrication and lubricators. This publication is a comprehensive one of its kind, and contains some information of an instructive and useful character for reference. It also includes particulars and illustrations of a great variety of oiling devices, etc.

ELECTRICAL COMPANY'S LITERATURE.—The following is a list of publications which we have received *en masse* from the Electrical Company, Limited, 121-125, Charing Cross-road, London, W.C.: Pamphlet No. 155 Nernst lamps for street and shop lighting; Leaflet No. 163, patent suspension chain; Card No. 166, flame arc lamp instructions; Leaflet No. 175, watt-hour meter; Leaflet No. 176, switchboard meter; Leaflet No. 177, new Nernst lamp reflector; Leaflet No. 178, artistic Nernst lamp fittings; Card No. XIII., 142/62, small motors; Card No. XIII., 146 A5, electric fans.

ALDERSHOT ELECTRICITY ACCOUNTS

The accounts of the Aldershot electricity department for the year ended March 31, 1905, show a total expenditure on capital account to that date of £25,619. Abstracts of the revenue account, balance-sheet, etc., are appended.

APPOINTMENTS VACANT.

Head of the Department of Physics and Electrical Engineering, Portsmouth Education Committee. Salary, £175 per annum. Application by Sept. 4. See advertisement.

Draughtsman for switchboards. Apply to Box H 91, *Electrical Engineer* office. See advertisement in last issue.

Draughtsman for works in North of England. Apply to Box O 8, *Electrical Engineer* office. See advertisement.

Canvasser, wages 25s. per week and commission. Letters only, Midland Electric Corporation for Power Distribution, Limited, 73, Lichfield-street, Wolverhampton. See advertisement.

Engineers in charge of a H.T. generating station. Salary from £7 to £9.—Apply to X 55, *Electrical Engineer* office. See advertisement.

District Representative for firm of manufacturing electrical engineers. Apply to "Electric," care of Hart's Advertising Offices, 6, Arundel-street, Strand, W.C. See advertisement.

LEGAL INTELLIGENCE.

A LONG-FIRM PROSECUTION.

At the Guildhall last week, George Webber, ironmonger, of High-street, Putney, and Richard Thomas Rosenberg, described as a motor-car driver, of 66, Gardener's-lane, Putney, surrendered to their bail to answer a charge of conspiring with others to obtain money and goods by false pretences.

Mr. BODKIN (who, with Mr. Boyd, appeared for the prosecution) said that defendants were charged with conspiracy with two other persons whose names were now public property—William Leslie, and a woman, Frances Cheeseman—to cheat and defraud various firms of electrical appliances manufacturers. Money and goods to the extent of many thousands of pounds were obtained by these four persons. Rosenberg posed as a "Mr. Knight" in connection with a company called the Electrical Accessories Co., which came into existence in November last. Its offices were at 83, Terminus-chambers, Holborn, and Rosenberg, *alias* Knight, in an affidavit had described himself as manager. The company's premises consisted of one small room in the back of a building that was formerly the Holborn Viaduct Hotel. So far as the prosecution were aware, no goods were ever stored in this one room occupied by the Electrical Accessories Co. Webber was an ironmonger who had been doing odd jobs for a year or two past at the Fulham Theatre, and in that capacity he came in contact with Leslie the electrician, who was engaged permanently at £3 a week. In December, 1904, the theatre changed hands, and it was just before this, and when the intending change would be known, that the Electrical Accessories Co. came into existence. Mr. Arthur, who was taking over the theatre, required the electric light installation seen to, and Mr. Henderson, the outgoing proprietor, requested Leslie to furnish an estimate of the cost of the material that would be necessary. Leslie gave his estimate—£53. This was the opportunity for commencing these frauds. Webber assumed the position of constructor of the electrical work to be carried out, which by this time had been considerably inflated, and sent out orders broadcast over London for many thousand pounds' worth of goods of all kinds connected with electrical appliances and motorcars.

After evidence had been called the case was adjourned.

Bail for Webber was fixed at £2,000, and for Rosenberg at £100.

BREAKING TELEGRAPH INSULATORS.

At Seaham Petty Sessions James Bolton was charged with committing wilful damage to telegraph insulators, the property of the Postmaster-General, on the Stockton-road, near New Seaham, on Aug. 6. Defendant pleaded guilty. Sergeant Jobling deposed that about 3 p.m. on the day mentioned he saw defendant and another young man sitting near a telegraph post on the Sunderland and Stockton road. Returning about an hour later witness found that two of the insulators on the post had been broken, and from inquiries made he found Bolton had broken them. When charged by the officer defendant admitted the damage. A fine of 10s. and costs and 5s. damage was imposed.

John Hogg and John Allen were charged with a similar offence committed on Aug. 9. Both pleaded guilty. Defendants, aged 10 and 12, were seen by P.C. Ogleby throwing stones at the insulators, four being broken. They were reprimanded by the Bench, and ordered to pay costs and the damage, 10s.

Robert Norman was also ordered to pay costs for attempting to break insulators. He threw stones at them, but did not break any.

QUESTION OF ROAD REPAIRS.

An application was made to the local magistrates last week by the Jarrow Corporation to compel the County of Durham Electrical Power Distribution Co. to put certain roads in repair.

Mr. JOHN PETREE, borough surveyor, stated that on July 21 he gave the company notice of dangerous places near the Hill-street railway bridge which had not been properly filled up. He had communicated with the company two or three times since, and it was impossible to obtain any reply. The object of the company, he alleged, was to put the responsibility on the town, and a summons was granted.

COMPANIES' MEETINGS AND REPORTS

CHLORIDE ELECTRICAL STORAGE.

The annual general meeting of this Company took place at the Works, Clifton Junction, on the 23rd ult., Mr. W. Bannister, J.P., presiding. Particulars of the report appeared in our issue of the 18th ult.

The CHAIRMAN, in moving the adoption of the report, announced a most successful year's training. The profit for the year was £27,298, and after deducting debenture interest, depreciation, and interim dividend paid in March last, and adding the amount brought forward from last account, the disposable balance of profit was £11,979. A dividend of 6 per cent. on the preference shares and of 8 per cent., free of tax, on the ordinary shares was recommended. These together amounted to £4,520, leaving to be carried forward to next account £7,459.

The report was adopted.

The retiring directors, Messrs. W. Bannister and J. de Berniere Smith, were re-elected; and Messrs. Parkinson, Mather, and Co. having been reappointed auditors, the meeting closed with a vote of thanks to the directors and the staff for their services during the year.

An extraordinary meeting was afterwards held for the purpose of making certain alterations in the articles of association, which were unanimously decided upon. The shareholders were subsequently conducted through the extensive new works, and were much impressed with the explanations of the different processes.

ABERDEEN SUBURBAN TRAMWAYS.

The half-yearly meeting of the Aberdeen Suburban Tramways Company was held last week at Aberdeen, Mr. George J. Walker, chairman of directors, presiding.

The report showed that the sum standing at the credit of the profit and loss account was £2,166. 1s. 9d., which the directors proposed should be applied as follows: in setting aside for a renewal and depreciation account, £1,000; in payment of a dividend of 2½ per cent. for the past year on the paid-up capital of the Company, £780. 19s.; and in payment of directors' fees, £42; leaving to be carried forward to next half-year's accounts, £343. 2s. 9d.

Digitized by Google

The CHAIRMAN, in moving the adoption of the report, stated that the question of depreciation had been carefully considered by the directors, who had obtained the fullest possible information as to the necessary requirements from past experience of other tramway companies in England and Scotland. Compared with the amount of the Company's capital it is a larger sum than is set aside by any electric tramway company last year, and larger than is set aside by the corporations of several towns where the tear and wear is as great or greater than on the lines of the Company. The Company's greatest drawback was, the chairman remarked, the price they had to pay the Corporation for energy—2¼d. per unit. He thought they might very well be supplied at 1½d., which was more than the Corporation trams were debited with.

The report was adopted unanimously.

NEW COMPANIES REGISTERED.

Torquay Tramways Construction Syndicate, Limited.—Capital, £140,000. Objects: to adopt an agreement with the Dolter Electric Traction Limited, and to carry on the business of railway and tramway proprietors, suppliers of electric light and power, electrical engineers, etc. Registered office: Queen Anne's-chambers, Westminster, S.W.

Sydsvenska Elektriska Aktiebolaget.—A Reuter's telegram states that a company has been formed at Halmstad, Sweden, under the above name for the purpose of generating electric power. The share capital is not to be less than 3,500,000 kronor (about £194,500), and not more than 10,000,000 kronor (about £555,500). The object of the undertaking is to supply the towns and industrial centres of the southern part of the province of Halland and the western portion of Scania with electrical power, which, in the first instance, will be generated by means of the Lagaa waterfall.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Stockport.—Tenders are required for supply and laying of cables. Tenders by Sept. 14.

Oban.—Tenders are required for supply and laying of feeders and mains. Tenders by Sept. 11.

Florianopolis (Brazil).—The Municipality require tenders for the lighting of the town by Oct. 2.

Plasencia (Spain).—The municipal authorities require tenders for an electric lighting installation. Tenders by Sept. 15.

Pontypridd.—The Urban District Council invite tenders for (Section A) permanent way. Tenders by 12 noon on Sept. 2.

Olympia 1905 Exhibition.—The Executive Committee invite tenders for the loan or hire of 300-kw. direct coupled steam set.

Carlisle.—The Guardians invite tenders for installation of electric bells from 15 wards at the Fusehill Hospital. Tenders by noon on Sept. 4.

Madrid.—The Public Works Department require tenders for the construction and working of an electric tramway in Zaragoza. Tenders by Sept. 12.

Bishop's Stortford.—The Urban District Council invite tenders for lighting such of the public streets as are at present lighted, for two or three years from Sept. 30. Tenders by 4 p.m. on Sept. 25.

Edinburgh.—Tenders are invited for the electric lighting installation at the mortuary buildings, High School Yards, Edinburgh, for the Lord Provost, Magistrates, and Council. Tenders by Sept. 11.

Alicante (Spain).—The Harbour Board (Junta des Obras del Puerto) require tenders for two electric cranes, capable of lifting 10 000 ko. and 1,500 ko. respectively. Tenders by Sept. 15. Estimate, 107,010·10 pesetas.

Chelmsford.—The Town Council invite tenders for lighting the public streets and public clock within the borough with electricity, gas, or other illuminating power for three or five years from March 25, 1906. Tenders by Sept. 8.

Ramsgate.—The Corporation invite tenders for a complete system of electric call bells between the new fire brigade station, Effingham-street, and the various firemen's residences within the borough. Tenders by noon on Sept. 4.

Paris.—The Waterworks Department of the Municipality require tenders for supply and erection of motors, pumps, and generators for the proposed waterworks at Chantilly. For particulars apply to above authority. Tenders by Oct. 12.

Ipswich.—The Guardians invite tenders for supply and erection of a dynamo and motor (to be made by Crompton and Co.), a battery booster, and alterations and additions to the main switchboard at the workhouse. Tenders by 10 a.m. on Sept. 14.

Stalybridge.—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery, and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

Merthyr Tydfil.—Tenders are invited by the Urban District Council for the erection of refuse destructor plant capable of effectually burning 120 tons of refuse per day, together with all buildings and contingent works connected therewith. Tenders by Sept. 1.

Dublin.—The Lighting Committee invite tenders for the supply of (*a*) sub station switchboards, transformers, etc.; (*b*) extra high-tension and low-tension mains. Tenders to Chairman of the Lighting Committee, 3, Cork-hill, Dublin, by Sept. 18. See advertisement.

Pembroke (Ireland).—The U.D.C. invite tenders for electricity supply mains, arc lamps and pillars, house meters, and switchboard panels. Tenders to Mr. J. C. Manly, Town Hall, Ball's Bridge, Co. Dublin, by 10.30 a.m. on Sept. 22. See advertisement in last issue.

Ashton-under-Lyne.—The Electricity Committee invite tenders for (Section A) one 500-kw. direct-current generator; (B) one water-tube boiler with superheater, to be worked in conjunction with a refuse destructor; (C) two superheaters for Lancashire boilers. Tenders by 12 noon on Sept. 2. It will be seen by a note and from an advertisement appearing among "Contracts Open" in to-day's issue, that tenders should be sent in addressed to the borough comptroller, Mr. John Neal.

Erdington.—Tenders are required for the construction of Section No. 1 of the Erdington tramways, comprising the laying of the permanent way, including copper bonding, wood block paving, and other works incidental to the laying of about 2½ miles of double-track tramway, for the Tramway Committee. Tenders to the joint engineers, Mr. Robert Green (of Messrs. Pritchard, Green, and Co.), of 37, Waterloo-street, Birmingham, and Mr. Herbert H. Humphries, engineer to the Council, Public Hall, Erdington.

Morton Banks (near Keighley).—The Keighley and Bingley Joint Hospital Board invite tenders for the following works at the isolation hospital, etc.: (1) for keeping the private telephones, wires, and apparatus, and the electric bells, wires, and apparatus at the hospital (including the small-pox hospital) in good working order and repair and properly charged for one year from Sept. 8 next; also (2) for the supplying and fixing of a lightning conductor and telephone for new diphtheria pavilion. Tenders by Sept. 4.

Municipal Board of Mussoorie (India).—The Municipal Board invite tenders for the supply, delivery, and erection at sites, in complete working order, of the following plant: (*a*) steel power pipes; (*b*) water-motors; (*c*) alternators with exciters; (*d*) switchboards with instruments and apparatus; (*e*) transformers; (*f*) induction motors; (*g*) pumps; (*h*) workshop machines. Also for the supply and delivery of the following: (*a*) bare copper wire for overhead mains; (*b*) insulators and lightning arresters; (*c*) arc and incandescent lamps; (*d*) telephone equipment; (*e*) workshop tools; (*f*) general stores. Specifications, form of tender, and general conditions can be obtained on application to Mr. C. H. Shanan, municipal electrical engineer, Municipal Office, Mussoorie, India (telegraphic address, Shanan, Mussoorie), on payment of a deposit of Rs.75 (£5), which amount will be returned on receipt of a bona fide tender. Tenders by Oct. 23.

RESULTS OF TENDERS.

Stirling.—The Town Council have accepted the tender of Messrs. J. and W. Brown, Glasgow, for the supply of Broomrigg nuts, at 7s. per ton, to the electric station for the year to June, 1906.

Neath.—The Rural District Council have accepted the tender of Messrs. Johnson and Phillips, Old Charlton, for four sub-station switchboards for the districts of Skewen, Melincrythan, Cadoxton, and Aberdulais.

Poplar.—The Board of Guardians have accepted the tender of Messrs. Ashwell and Nesbit for a continuous-current motor, at £45, and a 60in. Runwell exhauster fan, at £40. 10s., for the engine-house and pump-room at the workhouse.

Buxton.—The Urban District Council have sealed the following contracts at schedule prices for the electricity extensions: Callender's Cable and Construction Co. for supply of cable, and Ellison and Mitchell for supply of tar and liquor.

Earsdon (near Newcastle-on-Tyne).—The Urban District Council have received the following tenders for carrying out work in connection with the lighting by electricity of part of the district: Northern Electric Supply Co., Borough-road, North Shields, £214. 16s. (accepted); G. H. Armstrong, Chester-le-Street, £197; Ried, Ferens, and Co., Newcastle-on-Tyne, £295. 5s. 9d.

BUSINESS NOTES.

TRACTION.

Portsmouth.—There is a surplus of £21,000 on the year's working of the Corporation trams.

Kashmir.—The electric railway project is said to be now before the Government of India.—*Indian Engineering.*

Halifax.—The Tramways Committee have decided to introduce ½d. fares for children, commencing on Oct. 1.

Singapore.—It is reported that attempts are made daily to wreck the electric trams, which do not find favour with the inhabitants.

Bradford.—The Corporation have decided that they cannot accede to the men's application for a week's holiday per annum with pay.

Hastings.—The section from the High-street to Ore has been opened. Up to the 24th ult. the number of passengers since the opening of the line totalled 411,137.

Lancashire and Yorkshire Railway.—The Lancashire and Yorkshire Railway Co. have decided upon making a trial of roller-bearing axle boxes, made by the Empire Roller Bearings Co., on the electrical section of their system.

Dover.—The work of laying the double line on Crabble-hill has been completed, and gangs of men are now giving the finishing touches to the equipment on the road between the athletic ground and River Church. The line may be opened some time this month.

Leicester.—Alterations to the tramway lines are in progress with the object of relieving the congestion of traffic in Church-gate. A new siding is to be laid down on the Eastgate side of the Tower from the

Digitized by Google

West-end line to the Belgrave line, so as to relieve the congestion at the Church-gate siding.

Paris Metropolitan Railway.—The receipts of the Paris Metropolitan Railway for July illustrate the great progress the undertaking is making. The number of travellers was 10,122,390, as against 8,008,346 in the corresponding month last year, and the receipts represented £72,390, of which the Municipality takes £25,000.

Swansea.—Messrs. Dick, Kerr, and Co., the contractors for the tramway extensions, have sent in their bill for extras in connection with the permanent-way works, and this amounts to about £3,000, or 5 per cent. on the amount of the contract. The extras are mainly the result of the gas company's attitude over the gas-mains in certain thoroughfares through which the tramlines were laid.

Ipswich.—An inquiry was held last week by the Local Government Board with regard to an application on the part of the Town Council for sanction to borrow £19,550 for the purposes of defraying expenditure on works of street improvement in connection with the reconstruction of the tramways. The Corporation ask for 30 years for repayment of the loan, much of the work being of a permanent character.

Brighton by Motor 'Bus.—An experimental service of motor omnibuses was started from London to Brighton on Wednesday by the London Motor Omnibus Co., proprietors of the Vanguard service. The vehicle is a facsimile of those running in London. The journey, which, including an hour for stoppages, occupied 5½ hours, was performed satisfactorily. The fares at present will be from London to Brighton, outside seats, 7s. 6d., return, 12s. 6d.; inside seats, 6s. and 10s.

Liverpool.—Some excitement was caused on Tuesday evening through a tramcar leaving the lines at the bottom of Dale-street and rushing upon the footpath. The exact cause of the mishap is not clear, but it is surmised that the driver of the car lost control of his vehicle as he was turning from Byrom-street into Dale-street, with the result that the excessive speed caused it to leave the metals on the curve and continue its career over the footwalk. The damage was comparatively slight.

Electrocution.—A lamentable fatality occurred on Monday at the power station of the Hastings Tramways Co. A young electrician, Sidney Dixon, aged 21, was engaged in conducting a labourer named Benham round the works, instructing him which wires he should avoid and which were not dangerous. In the course of the walk round the station, and while still explaining the dangers which were to be avoided, he himself unwittingly rested his left hand on one of the live wires. In an instant he was rigid, and though Benham immediately pulled him away, he was past aid.

Keighley.—At the monthly meeting of the Town Council the town clerk reported that the provisional order with relation to the tramways in High-street and Bridge-street had been confirmed by Parliament. The Mid-Yorkshire Tramways Co. are applying to the Board of Trade for a year's extension of time for completion of the work authorised by their order of 1903, but it is not clear whether this applies to the Keighley section. The town clerk is to make inquiries. The system of return 1d. fares has not so far met with the degree of support from workmen that was anticipated. It will be continued for the present so as to give it a complete trial.

Bombay.—The Bombay tramways were to have been transferred to the new company on the evening of July 31, but on an application at the Bombay High Court on behalf of Mr. William H. Bingham, a rule *nisi* was granted against the Bombay Corporation and the Municipal Commissioner requiring them to show cause why they should not be restrained from granting any concession for the tramways and electric lighting purposes, referred to in the agreement of March 11, 1901, to any persons other than Mr. Bingham or his nominees and assigns, pending the hearing of the suit filed by him against the Bombay Corporation.—*Indian Engineering.*

Blyth.—At a joint meeting of the Blyth and Cowpen Urban District Council's last week, it was stated that over three years had elapsed since powers were granted to a company for the construction of tramways. It was decided that the directors of the company be asked to receive a deputation from the two Councils to ascertain if anything could be done to get the tramway system into operation as soon as possible. In the event of an unfavourable reply, the local authorities may approach the North Shields Tramway Co. with a view to an extension of their system, or in two or three years' time, when the two Councils are amalgamated, they may apply for powers themselves.

Spen Valley Tramways.—With reference to the application of the British Electric Traction Co. for leave to abandon a section of their Spen Valley tramway scheme, a letter has been addressed to the Board of Trade by the Liversedge Urban District Council. It is pointed out in this communication that the Council were induced to support the company's scheme by an undertaking that it should be carried out in its entirety, the details being embodied in an agreement at the time of the public inquiry at Dewsbury. With reference to the contention of the company that the lines already constructed do not pay, the letter remarks that, as less than two years have elapsed, it is too early to pronounce upon the financial possibilities of the line. In conclusion, the letter urges that consideration should be given to the needs of the inhabitants.

Electrification in America.—It is reported that the West Shore Railroad Co., with which Mr. W. K. Vanderbilt is associated, intends to electrify its line between Utica and Syracuse. Each car's equipment will consist of a 75-h.p. motor, operated by the Sprague-Thomson-Houston system of control, so that the cars can be coupled together and operated by a motorman in the front car. At Oneida it will be necessary to build a third or middle track over what is known as the Vernon grade. Middle tracks will be built at Canastota, and between New York Mills Junction and Genesee Street in Utica. The movement of the trains will be controlled by block signals, and there will be interlocking switches and signals at all points where switching will be necessary. There will be four electrical sub-stations, located as follows: Clark Mills, about two miles east of Vernon, at Canaseraga, and at Manlius Centre. It is stated that the contract for the equipment of the sub-stations and cars, amounting to some £40,000, has been awarded to the General Electric Co., of Schenectady.

Level Crossings.—A van driver named George Bettany, of Great Crosby, was summoned at the instance of the Lancashire and Yorkshire Railway for having obstructed and impeded a signalman in the execution of his duty. The defendant arrived with a horse and van at the St. John's crossing at 5.42 p.m., and as two trains were signalled to pass the signalman closed the gates, and after they had passed through he opened them again for traffic. The defendant then drove his horse and van to the centre of the crossing, where he came to a standstill, and although requested by the signalman to hurry up and get across as soon as possible, as another train was coming along, he refused, and used bad language, saying that as the signalman had kept him he would keep the signalman. While the defendant was on the crossing an electric train had to pull up. For the defence it was stated that the horse had been standing some seven or eight minutes before the gates were opened, and when it got on to the crossing it was seized with a fit of staggers, and would not move. The Bench dismissed the case.

Ramsgate.—Apropos of the recent accident, the *Globe* makes the following observations: "The tramway company will be undertaking a most serious responsibility if they continue to run their vehicles over the dangerous stretch in Madeira-walk. A man does not need to be an engineer to see that this piece of the line, with its excessively steep gradients, numerous sharp curves, and precipitous boundary at the most critical point, must be exceedingly perilous if the slightest thing goes wrong with the machinery of a car traversing it, or if the driver makes any error. Whether a lighter and more easily controlled vehicle than the heavy cars now in use might safely be employed is for the experts to decide, but there is no doubt but that the place, in existing circumstances, is a perfect death-trap, and the Board of Trade will, in our opinion, seriously neglect their responsibilities if they allow the present system to continue. The public have a right to assume that public vehicles shall be at least reasonably safe, and shall not be run under conditions which manifestly involve great risk, and if the Board of Trade cannot enforce this right, we really do not see of what use the department is."

New York Central Railway.—The New York Central has placed an order with the General Electric Co. and the American Locomotive Co. for 35 electric locomotives to haul the through trains of the system into New York City, and 176 cars to be used in the suburban service. The original order for 30 locomotives was placed some time ago, and as a result of the satisfactory tests on the first one the contractors have been instructed to proceed with the remaining 29, and the company has ordered five more, making 35 in all. The cars are similar to the cars now in use on the Interborough Railway. The total order is said to aggregate over £1,200,000 for electrical equipment. The engines, which are to be ready by Aug. 1, 1906, will weigh about 100 tons, having eight driving wheels with a diameter of 44in. apiece, and will develop 2,200 h.p. A telegram from the New York correspondent of the *Standard* states that "advices from Buffalo state that the New York Central Railway has purchased the undertaking of the Canadian Water Power Co., and has also purchased 60,000 h.p. from the American company. The capacity of the combined companies is 580,000 h.p. The New York Central's acquisition of these interests is believed to indicate a very extensive scheme of electrification on its system, beginning with the Syracuse-Buffalo section."

Perth.—A meeting of the Special Tramways Committee was held last Friday for the purpose of hearing the reply from the Board of Trade with reference to the height of the new cars. The Board have approved of the alteration in the height of the cars so as to enable them to pass under bridges. The committee have given instructions to the builders of the cars to have the alterations carried out immediately, and to send on the first car whenever it is completed. The resident engineer intimated that the postal authorities considered the arms on the poles erected along Scone-road were in too close proximity to the telegraph wires. If a storm of wind were experienced, in all probability the telegraph wires would break by coming into contact with the back parts of the arms. A suggestion was made that the parts of the arms in question should be cut so as to obviate the danger. Another point raised was in connection with the laying of Glasgow-road with granolithic blocks. The 18in. margins which the tramway contractors had to lay on each side of the lines were stated to have been improperly laid, consequent on the Town Council having ordered the remaining part of the street to be causewayed. In the above-mentioned section this margin had to be lifted, while it is said that where repairs are necessary to other streets the margins will also require to be put right. The committee instructed the engineer to report on the matter.

Wigan.—The following extract from the town clerk's report upon the omnibus Bill promoted by the Corporation and passed during the last session of Parliament relates to tramways. The measure authorises the construction of two additional tramways: (1) from the terminus of the existing tramway at Lamberhead-green through the urban district of Orrell to the Abbey Lakes; (2) from the terminus of the existing tramway at New Springs to Scot-lane, in the urban district of Aspull. The agreement between the Corporation and the South Lancashire Tramways Co. for the purchase of the tramway from Platt Bridge, through Abram and Golborne, to Lowton (or certain parts thereof), has also been confirmed, and it will be necessary within the next three months for the Corporation to serve a notice on the company stating whether they desire to purchase the powers to construct the whole of

Digitized by Google

the said tramway, or only a part thereof, but the part in respect of which the transfer of powers is required cannot be less than three miles, except in the event of the Abram Urban District Council refusing their consent to the proposed transfer unless the Corporation undertake to widen Dover Bridge, in which case the Corporation shall be at liberty to give notice in respect only of so much of the tramway as is situate on the north side of the bridge. The consideration for the transfer of the above-mentioned powers must be calculated at the rate of £1,000 per mile of tramway, the powers to construct which are transferred to the Corporation. The whole of the statutory powers relating to the Corporation tramways have been consolidated in the Act, which will be found a great convenience to those having to deal with the tramway undertaking.

The Underground.—The District Railway has commenced running a service of electric trains from Wimbledon and Putney to Whitechapel. With the exception of the Inner Circle service and the London and North-Western trains, the whole of the various services run by the District Railway are now being worked electrically. On Tuesday the final preparations were made for the removal of steam traffic on the District Railway system. Two special electric motors for hauling London and North-Western trains between Earl's Court and Mansion House, or any other companies' trains that may require in an emergency to use the company's lines, were attached to an ordinary London and North-Western train of 10 coaches, and a trial run was made from Mill Hill Park to South Harrow and back. The area selected includes many heavy gradients, but the trial proved quite satisfactory. It is reported that in two or three weeks' time the Metropolitan trains will be ready to run on the District system, the alterations to the collecting skate being well advanced. It is also stated that the Metropolitan Co.'s service of electric trains over its own part of the Circle will shortly be augmented. The electrical extension to East Ham, in connection with the Tilbury and Southend Railway Co.'s system, enabling passengers to travel between Richmond and East Ham without changing, is working satisfactorily. It is reported that Messrs. De Dietrich, of Luneville, France, are building a number of carriages for the Electric Underground Railways Co. Messrs. De Dietrich have already delivered 52 of these vehicles, and are now finishing 16 more, which will be delivered shortly.

London General Omnibus Co.—At the half-yearly meeting last week the chairman stated that out of the profits of the past six months another £20 000 had been transferred to the motor 'bus fund, so that a total of £40,000 had been set apart during the past 12 months for experimental motor services. Of that sum £6,800 had been expended up to June 30 last, leaving £33,000 in hand. They had organised a repair department under a competent engineering expert had trained practically a number of drivers, besides building omnibus bodies in their coach factory, and, as the chassis were delivered, they would be prepared to put more motor omnibuses on the roads under the most favourable working conditions. It was expected that before now the company would have had a larger number of motor omnibuses running. Those delivered had all been behind time, some were found on examination to be unsatisfactory, and the Board preferred to wait for machines which they believed to be reliable and durable rather than put a number of vehicles on the road which would probably result in a heavy working loss. He believed that the motor omnibus had come to London to stay, but he was equally convinced that some of those now working in our streets would cause their proprietors to wish that they had not embarked in so speculative an enterprise. For the first few months, or for a year, there was little or no difficulty in showing a good profit on the running of a service of new motor omnibuses, but maintenance charges increased with the age of the vehicles, and it would be interesting to watch the results of those undertakings which were dependent on motor omnibuses alone. For several years yet horse traction, which had given them such good results in the past, would be the backbone of this company.

Dundee.—At a meeting of the Tramways Commitee Mr. Fisher, the manager, presented a report as to the reason of the disparity between Dundee and Glasgow in regard to percentage of operating expenses to receipts. For Glasgow the figure is 49 per cent., while for Dundee it is nearly 63 per cent. The following figures apply to Glasgow and Dundee respectively: traffic receipts per car mile, 10·58d., 11·15d.; operating expenses per passenger, ·45d., ·59d.; cost of power per car mile, ·3d., ·63d.; traffic expenses per car mile, 2·91d., 2·9d.; general expenses per car mile, 1·04d., ·62d.; cost of maintenance per car mile, 1·01d., 96d.; total operating expenses per car mile, 5·26d., 7·11d. In explanation of this the report stated that the cost per car mile in Glasgow for power was ·3d., while in Dundee the cost was 2·63d.. a difference of 2·33 l. per car mile run. The mileage run in Glasgow during the year dealt with was 16,291,082, and taking this number at 2 33d., the difference per mile between Glasgow and Dundee represented a sum of fully £158,159. Adding this to the Glasgow working expenses (£356,820) gave £514,979, a sum equal to 71·C0 per cent. of their receipts, which amounted to £724,851. It was pointed out that in Glasgow, Huddersfield, and Leeds separate power stations were used for the tramways, consequently the cost for power placed to the debit of working expenditure on these undertakings did not include interest, sinking fund, depreciation, etc., on the power stations; while in the cases of Aberdeen, Burnley, Brighton, and Dundee the items for power included all these standing charges. The one item of power alone explained the difference referred to, consequently it was unnecessary to refer to other financial advantages which all the undertakings mentioned had as compared with Dundee. The committee ordered the report to be incorporated in the minutes.

Cairo Tramways.—The Cairo Tramways Co. (Société Anonyme des Tramways du Caire; registered office, Brussels) have always had under the Electric Tramways of Cairo Concessions Act the preference, providing there was no better offer forthcoming, for any extensions and new lines in that city and district. Under a new concession just signed they have obtained leave to construct five branches, as follows: A (to be constructed within two years)—From the Cairo main-line railway station along the Saptieh to the Schoobrah line. The public works department will reconstruct the road, kerbs, lighting and sewers, subways, etc., at the expense of the company. B (limit five years)—From the Boolak tram terminus to the Rod El Farag line, double line. C (limit one year)—From the Khalig and Abbassieh lines to the Abbas-avenue, double line. D (two years)—A small branch of the Schoobrah line, double line. E (Aug. 31, 1908)—Doubling of line in Old Cairo; £3,200 has been paid for this concession. F (after approval of bridges)—Ghizeh line (to the Pyramids), double line; £50,000 has been paid for this concession. This will connect systems on the right and left banks of the Nile. G (13 years)—From the Citadel to the El Imam Mosque, double line. H (one year)—Substitution of a line to the abbatoirs instead of part of the Khalig line. Phœnix rails, weighing 100lb. per yard, are specified for all new works and all repairs to new and existing lines, with the exception of the old line to the Pyramids, where Vignoles rails at 40lb. per yard are allowed. The company have to maintain a strip of 18in. on each side of the rails. The minimum radius for curves is fixed at 25m., except in special cases. The company must at their own cost provide for the uninterrupted passage across their line of the courses carrying the water required for irrigation and drainage purposes. The company have to acquire the necessary properties at their own cost; if necessary, they can act under the Public Expropriation Act. There is a penalty of £10 for stoppages save by *force majeure*. The company can only carry passengers and their small luggage, and must make no charge for such packages. The previous concessions are prolonged by five years, and all concessions expire Dec. 5, 1951, when the whole becomes the absolute property of the Government.

LIGHTING AND GENERAL.

Ripon.—The electric lighting order granted to the Corporation in 1901 has been revoked.

Northern Counties Electricity Supply Co.—The directors have declared an interim dividend at the rate of 5 per cent. per annum.

Liskeard.—The General Post Office are about to fix an overhead telegraph line, also three poles and the necessary stays in the new cattle market.

Personal.—Mr. J. C. Cooper, of Newcastle, has been appointed traffic superintendent of the Halifax Corporation tramways at a salary of £2. 5s. per week.

Portsmouth.—Last year's profits on electric lighting were £4,000, on telephones £1,500, and on tramways £21,000. Neither have ever drawn upon the rates.

Worksop.—It is proposed in connection with the proposed extensions at the electricity works to put down a water-softening plant estimated to cost about £250.

Leeds University.—The next session of the departments of civil, mechanical, electrical, and mining engineering will begin on Oct. 3. Particulars appear in another column.

British Insulated and Helsby Cables.—The directors have declared an interim dividend for the half-year ended June 30 of 8 per cent. per annum on the ordinary capital.

Catalogue.—The Electrical Power Storage Co., 4, Great Winchester-street, E.C., have issued a handy interleaved pocket catalogue giving full and illustrated particulars of their manufactures.

Ormskirk.—In consequence of the action taken by the Board of Trade with regard to Wisbech, as mentioned in our issue of the 18th ult., it is doubtful whether the Ormskirk scheme will be proceeded with.

Malton.—The agreement with the Northern Counties Electricity Co. for the lighting of the town has been signed, and the Council have asked the company to complete the work with all possible speed.

Calcutta Electric Supply Co.—The number of units delivered to consumers during the four weeks ending July 28, 1905, were 416,207 compared with 318,617 in the corresponding four weeks of the preceding year.

Stock Exchange.—Application has been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to Electric Supply Co. of Victoria £160,000 5 per cent. first mortgage debenture stock.

New Icelandic Cable.—It is announced from Reykjavik (Iceland) that both sections of the Althing have now finally approved the agreement with the Great Northern Telegraph Co. for the establishment of cable communication between Iceland and the Shetland and Faröe Islands. The cable is to be completed by the autumn of 1906.

Telephones to France and Belgium.—On and after to-day the London subscribers to the National Telephone Co. will be able to use the Anglo-French and Anglo-Belgian telephone services on the same conditions as Post Office subscribers, and similar facilities will be available to the company's subscribers connected with the main exchanges in the provincial towns with which communication is practicable.

Stirling.—Reports by Mr. Hanson show the following progress of the electric light undertaking: for the four weeks ending June 10 the total in equivalent 8 c.p. lamps connected for all purposes was 17,392; July 8, 17,452; Aug. 5, 17,466, as compared with 15 334 for August last year. A revised scale of charges for public lamps, making the charge for each type of lamp uniform, and so effecting a slight decrease on the total charge, has been approved.

Dundee.—With the view of increasing facilities for motive-power customers, Mr. Richardson, the engineer, has proposed that arrangements should be made for utilising certain of the tramway feeders for the supply of current for power purposes only to industrial establish-

Digitized by Google

ments on the line of the tramway routes. The committee have received the proposal favourably, and have asked Mr. Richardson to prepare a detailed report for further consideration.

Greenwich.—The construction and fitting up of the huge generating station at Greenwich, which is destined to generate the electric current for the London County Council trams, was commenced in the autumn of 1902. The work will not be completed till next year, and meanwhile the Council buys its electricity from a private company. As the County Council have decided to electrify the North London system without delay, the work of the second portion of the Greenwich station has been put in hand, and will be completed in 2½ years' time.

Glasgow and West of Scotland Technical College.—The next session begins on Sept. 26, in the new buildings recently erected for the college. The diploma of the college is granted in the following departments: civil engineering, mechanical engineering, electrical engineering, mining, naval architecture, chemistry, metallurgy, mathematics, and physics. In conjunction with the Glasgow School of Art a course for a joint diploma in architecture has been arranged. Particulars appear in another column.

Stourbridge.—At the last meeting of the District Council the Electric Powers Committee asked for permission to negotiate with the Shropshire, Worcestershire, and Staffordshire Electric Co. with a view of the Council taking current from them in bulk on similar terms as were proposed in the agreement formerly proposed with the Midland Electric Corporation, who found they could not legally supply the town. On account of the delay which has arisen, notice was given of a motion instructing the committee to take immediate steps to generate their own current. This resolution, it was explained, would be withdrawn if terms were arranged with the Shropshire and Worcestershire Co. before the next Council meeting.

Morse Chain.—We are informed that the Westinghouse Brake Co. have secured the exclusive rights, under the Morse chain patents, to manufacture and sell the Morse rocker joint silent high-speed chains in Great Britain and on the continent of Europe, and have just completed a new building at York-road, King's Cross, N., for the manufacture of these chains. The new works are equipped with a selection of the most modern machine tools for chain making and testing, and the Westinghouse Brake Co. are now prepared to supply these chains to suit every description of power transmission. The Morse rocker joint chains with the double-pintle design to eliminate all sliding friction have met with great success since their introduction in America.

Stoke Newington.—Hitherto supply has been taken in bulk from the Hackney Borough Council, the supply being given at two feeder points at 480 volts across the three-wire system of direct-current distributors. The demand has outgrown the system, the Hackney authorities being unable to serve the rest of the district on the low-tension system at a reasonable rate of charge. Power is now to be taken in bulk on the three-phase system at 10,000 volts served from the Brimsdown works of the North Metropolitan Electric Power Supply Co., and will be transformed to 480 volts direct current, three-wire. For the latter purpose a sub-station is being erected at Edwards-lane, and this work and the extension of mains will not be completed until the end of the year.

Improvements in Trestles and Steps.—Occasionally the wireman or lamp attendant needs tall trestles, but more often shorter ones and at times a ladder, and it has been the rule to keep these items at hand in the shape of separate articles, but for the future this need not be the case, as Mr. Heathman, of Parsons Green, Fulham, who has given us so very many improvements already, has made another and patented it, so that now the two sides of trestles or steps can be separated and used as two ladders, or put together to slide up and make a longer ladder, or hinged together as trestles. And two of these when extended as a ladder can be "coupled" together to form tall trestles, and even a bit more, one side can be longer than the other so as to stand upon inclines or staircases.

Cambuslang.—The works which the Lanark County Council are erecting at this place will be equipped with two Lancashire boilers by Penman, worked at 200lb. pressure, two Howden 80-h.p. engines, and two Parker 55-kw. dynamos. In conjunction with this plant a Meldrum three-cell destructor is to be worked. The feeders are 2 triple-concentric cables laid in Howard troughing, and the distributors are three-core and armoured laid direct in ground. The supply will be given on the three-wire system—250 volts for lamps and 250 and 500 for motors. The charges for current will be as follows: private lighting, 4d. flat rate; power, 2d.; street-lighting, 3d. The consulting engineers for the works are Messrs. Hunter and Jack, and the resident engineer is Mr. A. J. Abraham, A.M.I.E.E.

Agency.—Mr. A. H. Hunt, 115-117, Cannon-street, London, E.C., has been appointed agent in London and suburbs for the sale of the Reason Manufacturing Co.'s arc lamps. Owing to increasing demand the company have extended this department of their works at Brighton, and are now making enclosed arc lamps for both alternating and continuous current working in the standard and also the miniature sizes. The company are making a speciality of twin-carbon lamps, both miniature and standard sizes, for running direct on 200 to 250 volt circuits—a great advantage in the case of a change over from low to high voltage. The chief feature in the Reason lamps is that under their patents they are able to entirely dispense with shunt coils, thereby eliminating what has always been a source of trouble to arc lamp users.

South Shields.—The last electricity account shows a total capital expenditure of £151,838 of which £2,481 was spent during the past year, principally for machinery, meters, and connecting consumers. Receipts amounted to £18,346, and the payments, including interest and redemption, to £16,358, leaving a balance of £1,988. The balance on revenue account at the beginning of the year was £1.709, to which was added the profit of the year, amounting to £1,988, making a total available balance of £3,698. This sum was disposed of by transferring £1,304 to reserve fund and £300 to the relief of the general district rate. The balance of £2 094 has since been added to reserve, making the latter over £4,000. Out of the profits of the Mill Dam Quay £300 has also been devoted to the relief of the general district rate.

Malton (Yorks).—The Northern Counties Electricity Supply Co. are erecting electricity works at this place, which are to commence supply of current on Oct. 25. The system chosen is the three-wire, with 230 volts for lighting and 460 for motors. Power for the former will be supplied on a sliding scale of 5½d. to 4d., and for the latter 2½d. to 1½d. The street-lighting has been contracted for at a charge of £362 per annum. The plant consists of two Crossley gas-engines of a total of 120 i.h.p., two Bruce Peebles dynamos, and Chloride L R type accumulators of a normal output of 75 kilowatt-hours and maximum discharge rate of 150 amperes. The feeders and distributors have been supplied by Callender's Cable and Construction Co. The work is being done under the direction of the company's engineer, Mr. C. S. Vesey Brown, the resident engineer being Mr. J. Chandler.

York.—The estimated income and analysis of cost of the York electricity department, which will be laid before the York City Council at the meeting on Monday is as follows: units generated—public lamps, 5,869; power and private lighting, 41,464; used at works, offices, and battery, 6,463; unaccounted for, 5,183—total, 58,979. Estimated income—public lighting, £99; power and private lighting, £421. 3s. 1d.; motor and radiator rents, £35—total, £555. 3s. 1d. Total estimated income per unit sold, 2·81d.; horse-power of motors connected during month, 26; total horse-power of motors connected to date, 717; 8 c.p. lamps connected during month, 261; total 8-c.p. lamps connected to date, 47,907; equivalent 8-c.p.'s connected—total, 65,832. The city electrical engineer is about to prepare estimates for the lighting of Gillygate and Fishergate by arc lamps, cables having been already laid in these streets.

Frinton.—Messrs. Christy Bros. and Middleton have reconstructed the Frinton-on-Sea electric light station within a week of its destruction by fire on Saturday, 19th ult. Part of Monday was occupied in clearing the ground, and the local contractor, Mr. A. E. Farr, has since raised the building to a height of 12ft., and has erected a substantial temporary roof. Night and day shifts were worked. The new building is 60ft. long by 28ft. wide, handsomely built in white brick with red brick piers, strongly cemented, and with a stout party wall dividing the engine-house from the accumulator room. The 40-h.p. Crossley gas-engine has been restored, and is again in perfect order, whilst the smaller engine will probably be also running in a couple of days. The Frinton Electric Light Co. are now supplying current up till 12 15 each night. New accumulators will be placed in position in a day or two. On Friday evening last a concert was given for the benefit of the station engineer, Mr. Hockley, who lost a good deal of personal property—including his wedding presents and a new bicycle—through the fire.

Trowbridge.—The Urban District Council have received a report by Messrs. Talbot and Stevenson on the cables laid by the Western Electric Distributing Corporation, in which they express an adverse opinion on the laying of the cables directly in the ground without troughing or protection of any kind, as the ground undoubtedly contained corrosive matter, but they do not consider that there is any cause for apprehension of danger to the public resulting from an accidental puncture of a protected cable by pick or other tool. On the question of the Corporation's responsibility for damage caused to the side paths, they thought it would be reasonable to insist upon their laying the cables in the roads. They had formed the opinion that the Corporation intended to faithfully fulfil their obligations—that was to say, to complete the work and give the supply within the stipulated time. They were naturally anxious to keep down the capital expenditure, and to ensure a satisfactory financial result. The letter was referred to the Lighting and Paving Committee and the Electricity Committee for report. The question of costs was referred to Mr. Pearson, of Bristol, with full powers.

Todmorden.—To-day has been fixed for the opening of the electricity works, which have been equipped from the plans of Mr. H. Waring, the Corporation's electrical engineer. The sum authorised for the purpose was £20,000, and of this £16,500 has been expended up to date. The structure has cost £6,000, machinery £3,200, meters and instruments £700, mains and services £4,500, and accumulators £1,100. Two Lancashire boilers, worked at 160lb. pressure, have been supplied by Messrs. Yates and Thom, and a Green's 96-tube economiser is also installed. Two Belliss and Morcom engines of a total horse-power of 370 are in position, and also two Bruce Peebles dynamos of a total capacity of 225 kw. The accumulators are of the E.P.S. Co.'s P-11 type (260 cells), and give a normal output of 600 ampere-hours and a maximum discharge rate of 250 amperes. Both feeders and distributors are single cables, paper-insulated, lead-covered, and laid solid. The station is to be worked in conjunction with a Meldrum refuse destructor, and the electrical supply will be given on the three-wire system at 230 volts for lamps and 230 and 460 for motors. The charge for lighting is a flat rate of 5d. and that for power 3d. The Corporation own the gasworks, the charge for gas being 2s. 6d. per thousand cubic feet.

Aberdeen.—The electricity accounts for 1904-5 show a revenue of £39 047, made up as follows: Sale of current per meter, £23,964; public lighting, £2,319; traction (Corporation), less £1,137 difference between amount charged and actual cost, £9,890; traction (Suburban), £1,357; hire of motors, £840; and attendance on harbour and fish market lamps, £617. The expenditure under this account amounted to £17,037, including fuel, £5 875; wages at generating station, £1,779; repairs on plant, £934; main and service repairs, £987; taxes, £3,402; and engineer's salary (proportion), £513. The balance carried to net revenue account was £22,009. The amount paid in interest on mortgage and loans was £7,694; depreciation on

Digitized by Google

buildings, machinery, etc., accounts for £6,723; £4,891 is added to the sinking fund; and the surplus carried to the reserve fund amounts to £2,753. At July 31 the amount at the credit of the reserve fund account was £16,336. The amount expended on works in the general balance account was £269,329, less depreciation written off, £31,882—£237,441. The total assets amount to £275,448. During the year the quantity of electricity generated was 4,899,050 units, as compared with 4,158,141 units last year. The total amount sold was 4,069,831 units, compared with 3,539,026 last year. Of the total quantity sold 2,105,279 units went for traction, 1 709 012 units to private consumers by meter, and 255,540 units were consumed by the public lamps. The quantity used in the works and subway was 377,793 units, the total quantity thus accounted for being 4,447,624 units. The quantity lost in distribution or otherwise not accounted for was 451,426 units—a percentage of 9·21. The total number of arc lamps is 127, the same as last year. The prices per Board of Trade unit were 6d. and 2d., 6d. and 1½d., 3d. and 1d., 2½d. and 1·2108d.

Yorkshire Electric Power Co.—The new power station which the company have erected at Ravensthorpe has during the last week been thrown open to visits from municipal representatives, the Midland Institute of Mining Engineers and the Colliery Managers' Association, etc. The company some years ago acquired parliamentary powers for supplying current throughout and beyond the industrial portion of the West Riding—from Goole to Skipton and from Wetherby to Sheffield, 1,800 square miles in all. This is the first station they have completed. Three other stations will be erected as occasion demands, but for the present the company expect to be able to distribute current on advantageous terms within a radius of 20 miles. Already mains have been laid in the districts of Thornhill, Dewsbury, Soothill Nether, Ravensthorpe, Mirfield, Kirkheaton, Liversedge, Gomersal, Birkenshaw, Drighlington, Leeds, and Pudsey. The company are now supplying electricity in bulk to the local authorities of Pudsey and Mirfield, and agreements are in process of completion with the Councils of Birstal and Liversedge. Current for industrial purposes is, in fact, being supplied to mills at Gomersal and at Pudsey, the use of electricity increasing the output by something like 15 per cent. Electric installations have also been made at the mines at Chickenley Heath, Mirfield Moor, the Farnley Iron Co. at Three Nuns, and of the Low Moor Co. at the Calder Colliery The engine-house is designed to contain generating plant of 8,450 kw., or 11,000 h.p., capacity, and extension can be made to secure a capacity of 60 h.p. Provision has been made for six boilers, four already having been installed, and the stoking is accomplished by an ingenious electrically-driven contrivance, by which one man can see to the feeding of two or even three boilers. The main generating sets are Curtis turbo-generators, the turbines running at a speed of 1,000 r.p.m. The alternators attached to the turbines generate three-phase alternating current at 10 000 volts. An interesting feature of the engine-house is the gigantic control switchboard, from which the whole of the main switchgear is operated by means of low-pressure current. The main switches are worked by means of small motors. Working at top speed the station can generate more than 250,000 units per week.

Grimsby.—The electrical engineer's monthly report shows that the number of private lamps and motors connected and applied for was 45,842 in July, as against 45,931 in June, being a decrease of 89. The number of services run showed an increase of four, while there was one more consumer. Units had been sold for traction purposes to the number of 36,627 in July, as against 36,452 in July last year, being an increase of 175; public lighting £4,323, a decrease of 32; and to private consumers 23,604, an increase on last year of 17,126. The decrease in the number of lamps connected was due to the temporary lights for illuminations having been connected last month and disconnected this month. The recommendation to borrow £18,000, noted in our last issue, has been approved. The following estimate has been prepared: engine and dynamo, 500 kw., speed 350 r.p.m., delivered and erected, £3,400; boiler, with automatic stokers, etc., normal evaporation 14,280lb. of water per hour, £1,220; switchboard, one panel for dynamo and three sets of feeder fittings, £120; feed pump, 4,000 gallons per hour capacity, £100, less value of small pump 1,000 gallons capacity, which has to be removed, £60; pipework, steam exhaust, circulating water, drains, and all necessary pipes, £830; condenser, with necessary motor-driven pumps, £1,200; water purifier, increasing the capacity of the present plant from 1,500 to 3,000 gallons per hour, £160; building extension of engine-room, £900; foundations, boiler setting, etc., £400; coal conveyor, £400; sundries and contingencies, £810—total cost of new plant, £9,500. Estimate of mains work to be carried out during the next three years: new store for meters, cables, etc., £230; mains, feeders, distributors required during next three years to supply consumers, including 460 yards of feeder to connect up to the feeder laid by the railway company on their own property, £4,790; estimated expenditure on services, £2,100; estimated expenditure on meters, etc., £1,380—total cost of mains work, £8,500. Total capital expenditure during the next three years: plant, £9,500; mains, £8,500—total, £18,000. At the last Council meeting it was also proposed that the scale of discounts to consumers for current for lighting purposes be altered, and that the charges for current for lighting in future be as follows: for the first 20 units per quarter 7s. 6d., and for all current above this at the rate of 4½d. per unit, subject to discounts as follows: for a consumption exceeding 20 units and not exceeding 250 units per quarter, 5 per cent.; 250 units and not exceeding 500 units, 7½ per cent.; 500 units and not exceeding 1,000 units, 10 per cent.; 1,000 units and not exceeding 2,000 units, 12½ per cent.; 2,000 units, 15 per cent. The discounts only to be allowed for payment of account within 21 days after presentation, time to be the essence of the contract note. The engineer pointed out that the present scale of charges was as follows: for the first 20 units per quarter 7s. 6d., for all current above this at the rate of 4½d. per unit, subject to discounts as follows: exceeding 500 units and not exceeding 3,000 units, 2½ per cent.; 3,000 units and not exceeding 5,000 units, 5 per cent.; 5,000 units and not exceeding 8 000 units, 7½ per cent.; 8 000 units and not exceeding 11 000 units, 10 per cent. Discounts allowed at the end of each year for cash within one month. An amendment that the matter be not entertained that night was carried.

Rochdale.—With regard to the partial shut-down here on Saturday, the 26th ult., we are informed that at about 8.30 p.m. the main fuse on one of the generators supplying the lighting mains blew, and as only one machine was then running, the supply, of course, was thus cut off from the town. The generating plant consists of direct-current machines and three-phase alternators, also a motor-alternator which is capable of receiving three-phase current, and generating for either tramway or lighting purposes, and also *vice versâ*. At the above-mentioned time one machine was running the lighting load and one the traction load. This latter was assisted by the motor-alternator receiving its supply from one of the steam-driven alternators, the exciting current for the steam alternator and also the motor-alternator being supplied from the lighting 'bus bars. The condensers and station motors were also being supplied from the lighting 'bus bars, as well as the lighting arrangement in the station. The blowing of the fuse cut off the excitation of the alternators and also the supply to the various motors and station lighting. The loss of vacuum threw off the steam sets on to the atmospheric exhaust main, which naturally to a certain extent reduced the power of the sets. The traction load was too much for the direct-current machine supplying, and was further added to by the fact that, the motor-generator losing its excitation on the alternate-current side, the direct-current side received current, and was motored off the traction 'bus bars, the alternate-current machine becoming a generator driving the alternate-current steam generator, thus throwing a heavier load still on the traction machine. The latter started pulling up, and it was necessary to trip the automatics on some of the traction feeders rather often so as to relieve the machine. It was about half an hour before the tramway supply was righted, but it was never totally stopped. As the machine fuses on the lighting board had not previously given any trouble, it appeared probable that it was due to some fault on the mains (during the last few days a number of faults have occurred due to cables being damaged during the tramways construction and also by some work carried out by other departments of the Corporation). It afterwards proved that the fuse had been faulty. A separate machine was run up to take the station lighting and motors, and in the meantime the lighting network had, to a certain extent, been sub-divided. Some difficulty was experienced in recommencing the supply, as, of course, only having motor balancers and a motor-generator, which alone would not be sufficient to take the load, the engines had to be run up and kept on the stop valve until such time as the balancers could be got in. As soon as this was done the various sections of the distributors had to be reconnected, which accounted for the main portion of the delay in renewing the supply. The various sections of the town were out from periods varying from 10 minutes to 1½ hours, but by 10 o'clock everything was straight again. This is the first complete shut-down due to any fault in the generating station since the plant commenced supply in October, 1900, and is not a bad record when it is remembered that during that time for many months the station had to be run without any spares, and, further, that during the last winter both the traction and lighting switchboards were completely dismantled, and temporary arrangements had to be made until such time as the reconstructed boards could be erected and connected up in their new positions in the switch-room.

PROVISIONAL PATENTS, 1905.

AUG. 21.

16891. Improvements in electric heating apparatus. Charles McIntyre and Alfred Upton Alcock, 1, Queen Victoria-street, London.

16905. Improvements in and relating to electric alternating-current machines. Pierre Antoine Joseph Lapeyrade, Thanet House, Temple Bar, London. (Date applied for under Patents Act, 1901, Aug. 23, 1904, being date of application in France.) (Complete specification.)

16936. Improvements in the electrolytic manufacture of copper wire strip or the like. Sherard Osborn Cowper-Coles, 4, South-street, Finsbury, London.

16943. Improvements in and relating to electric resistances. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

16945. Improvements in or relating to apparatus for automatically lighting and extinguishing electric lamps of a circuit at certain hours varying with the seasons. Ernest Capt-Lecoultre, 111, Hatton-garden, London. (Date applied for under Patents Act, 1901, Sept 3, 1904, being date of application in Switzerland. (Complete specification.)

AUG. 22.

7006A. Improvements in earth galvanic cells. Emil Jahr, 73, Cheapside, London. (Date applied for under Rule 5 of the Patents Rules, 1905, April 3, 1905.) (Complete specification.)

16971. Improvements in, or in and relating to, commutators of dynamo-electric machines and electric motors. William Armistead, Prince's-chambers, Wolverhampton. (Complete specification.)

Digitized by Google

16983. **Improvements in magnetic trembler sparking plugs for electric ignition of gases.** Rankin Kennedy, 60, Norse-road, Scotstoun, Glasgow.

17032. **Improvements in electrically-operated fans.** William Phillips Thompson, 6, Lord-street, Liverpool. (The firm of Reiss and Klemm, Germany.) (Complete specification.)

AUG. 23.

17043. **Improvements in electric alarm apparatus.** William Ashburn and William Bamber Ashburn, 6, Bank-street, Manchester.

17050. **Improvements in the distribution of electricity on the overhead wire system.** James Robson, 3, Devonshire-place, Selby Park, Worcestershire.

17079. **Improvements in and relating to receivers for electric waves.** Ferdinand Schneider, 60, Queen Victoria-street, London. (Complete specification.)

17084. **Improvements in and relating to electric train-lighting systems.** Siemens-Schuckertwerke, G. m. b. H., Queen Anne's-chambers, Broadway, Westminster, London. (Date applied for under Patents Act, 1901, Aug. 25, 1904, being date of application in Germany.) (Complete specification.)

17091. **Improvements in audible electric signalling apparatus.** Willie Dickson Kilroy, Sydney Evershed, and Evershed and Vignoles, Limited, 1, Queen Victoria street, London.

17093. **Improvements relating to magnets for electrical measuring apparatus.** Josef Herman, 322, High Holborn, London.

17106. **Improvements in or connected with arc lamps.** Erwin Rudolf Grote and Milton Victor Ely, 40, Chancery-lane, London.

17107. **Improvements in or connected with enclosed arc lamps.** Edwin Rudolf Grote and Milton Victor Ely, 40, Chancery-lane, London.

AUG. 24.

17116. **Improvements in or relating to certain parts of phonographs, gramophones, and the like.** The Electric and Ordnance Accessories Company, Limited, and Robert Frederick Hall, 24, Temple-row, Birmingham.

17126. **Manufacture of tyres and wheels for motor cars and other vehicles propelled by steam, electricity, oil, or any other motive power.** Frederick Rodgers, Hope, near Sheffield.

17133. **An improved lifeguard to be attached and driven forward for electric tramcars, steam cars, engines, or any other locomotive driven on roads, rails, or metals.** John Stanley Bailey, 29, Princess-street, Manchester.

17152. **Improvements in apparatus for agitating electrolyte alkaline or other solutions during electroplating, depositing, boiling, or mixing processes.** Francis John Clarke, 138, Birchfield-road, Birmingham.

17170. **A device for conveying fresh air, telephonic and other messages to the interior of submerged submarines, applicable also for other purposes.** Frederick Arthur Smith, 165, Queen Victoria-street, London. (Complete specification.)

17181. **Improvements in thermo-electric couplers.** British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.) (Complete specification.)

AUG. 25.

17133. **Improvements in and relating to mercurial vapour electric lamps.** Joseph Skwirsky and Francis Harrison, 157, Grange Park-road, Leyton, Essex.

17204. **Improvements in dynamo-electric generators and motors.** Frank Johnston, 55, Spencer-road, Bedford, Beds.

17222. **Improvements in electrical transformers for measuring apparatus and the like.** Camillo Olivetti and Dino Gatta, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Aug. 25, 1904, being date of application in Italy.) (Complete specification.)

17223. **Wireless telegraphy.** Walton Harrison, 1, Broad-street-buildings, Liverpool-street, London. (Date applied for under Patents Act, 1901, Aug. 26, 1904, being date of application in United States.) (Complete specification.)

17235. **Improved construction of appliances for producing electric light displays.** Alexander Elias Dakhyl, Antonio Galanti, and Hanna Nassyf Dakhyl, 173, Fleet-street, London.

17238. **Improvements in electrodes for secondary batteries.** Henry Francis Joel, Norfolk House, Norfolk street, Strand, London.

17243. **Improvements in electricity meters.** Hermann Aron, 47, Lincoln's-inn-fields, London. (Complete specification.)

17257. **Improvements in automatic switches for telephone installations.** Paul Hildebrand, 31, Bedford street Strand, London. (Complete specification.)

AUG. 26.

17260. **An electric indicator for showing, at a distance, the rise and fall of liquids in reservoirs and the like.** William John Blenheim, 3, Grange-road, Egham.

17270. **Improvements in or connected with electrical hand lamps.** Claude Gerald Napier-Clavering, 48, Corporation-street, Birmingham.

17280. **Improvements in and relating to magneto ignition apparatus for use with internal-combustion engines.** Josef Gawron, 51, Deansgate-arcade, Manchester. (Date applied for under Patents Act, 1901, Aug. 26, 1904, being date of application in Germany.) (Complete specification.)

17283. **Improvements in or applicable to automatic breakers for electrical apparatus.** Heber Moorhouse, 4, St. Ann's-square, Manchester.

17286. **Improvements in or relating to electrical contact makers and breakers, particularly for use in conjunction with internal-combustion engines.** Frederick Henry de Veulle, 18, Hertford-street, Coventry.

17288. **Improvements in electric candle lamps.** Charles Clark Regnart, 29, Anson-road, Cricklewood, London.

17302. **Improvements in or relating to telephone or like transmitters.** Hahnemann Adolphus Outmore and the Telaupd Syndicate, Limited, 315, High Holborn, London. (Complete specification.)

17308. **A new or improved apparatus for producing electrical discharges.** Herbert John Haddan, 31, Bedford-street, Strand, London. (The Synchronous Static Company, United States.) (Complete specification.)

17312. **Improvements relating to telegraphic signalling systems.** Giovanni Bogni, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Aug. 31, 1904, being date of application in Italy.) (Complete specification.)

17314. **Improvements in automatic regulators for electric currents.** Patrick Kennedy, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Nov. 12, 1904, being date of application in United States.) (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Sept. 14.

1904.

11668. **Electric telegraphy.** Muirhead.

16038A. **Central exchange telephone system.** Brander. (Date applied for under Patents Rule 9, July 20, 1904.)

17975. **Control of electrically-propelled vehicles.** Raworth.

18105. **Transformation of repulsion motors, when running at speed, into rotating field asynchronous motors.** Latour. (Date applied for under International Convention, Aug. 27, 1903.)

18163. **Arc lamps** Andrews.

18174. **Speed-changing mechanism.** British Thomson-Houston Company, Limited. (General Electric Company.)

18185. **Means for controlling electric power distributing systems.** Routin.

18683. **Control of alternating-current electric motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

18790. **Apparatus for indicating and recording electrically at a distance the movements of instruments indicating physical conditions.** Le Page. (Post-dated Sept. 30, 1904.)

20314. **Electric capstans.** Dixon.

20554. **Apparatus adapted for indicating or automatically controlling or varying the flow of electric current.** Fricker.

20672. **Connection of electric or other wires.** Ford and Sadworth.

21045. **Single-phase dynamo-electric machines.** Carolan. (General Electric Company.)

21401. **Method of effecting communication between telephone exchanges and apparatus therefor.** Thomson.

21422. **Electrical switches.** Nunns.

22744. **Electric switches.** British Thomson-Houston Company, Limited. (The General Electric Company.)

22820. **Variable-speed windings for alternating-current motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

22822. **Alternating-current electric motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

23201. **Third rail insulators of electrical railways.** Chambers.

25191. **Application of a coherer to any electric transmission by means of conductors for any distance, for telegraphic, telephonic, signalling, bell, or other systems.** Magini.

25406. **Method of amplifying variations of energy in electric circuits.** Hewitt.

1905.

860. **Trolley heads for overhead system of electrical traction.** Orme.

1247. **Conduits for the protection of electrical conductors.** Maxwell.

1380. **Telephone systems.** Watkins, Bolster, and Goodsell.

2922. Electric accumulators or secondary batteries. Vickers, Sons, and Maxim, Limited, and Hall.

2944. Rectifiers for alternating electric currents. De Faria. (Date applied for under International Convention, Feb. 20, 1904.)

5369. Electric motor meters and other measuring instruments, more especially designed for reducing the effects of friction in such instruments. Davis and Haskins. (Date applied for under International Convention, March 15, 1904.)

5577. Telephone calls. Geyerman.

6640. Electricity meters. Busch and Roosen.

6640A. Electricity meters. Busch and Roosen. (Date applied for under Patents Rule 9, March 29, 1905.)

7159. Telephone apparatus. Ehrlich.

7498. Air-insulated telephone and telegraph cables. Emanuel Jensen and H. Schumacher Aktieselskab. (Date applied for under International Convention, April 9, 1904.)

8615. Electric switches. Jones, Macmillan, and Neybergh. (Date applied for under International Convention, Jan. 12, 1905.)

9439. Fireproof casings and covers for electric conductors. Romney.

10067. Treating of patients by static, galvanic, or like electrical currents. Macaura.

10112 Insulating base for electric switches, plugs, pushes, and the like. General Contract Company, Limited, and Salamon.

10187. Electric couplings. Boutfield. (Firm Julius Pintsch.)

11773. Magneto-electric ignition apparatus for petrol engines and the like. Simms and Bosch.

12822. Electric door-locking device. Peter.

NOTES.

Wireless Telegraphy.—In consequence of applications for patents having been presented to the Canadian Government by Mr. de Forest, Mr. R. A. Fessenden, and Sir Oliver Lodge, a dispute has arisen as to which was the inventor of certain arrangements of apparatus for wireless signalling. The parties have agreed to refer the matter to the arbitration of Messrs. Aylen, K.C., Ridout, and Thompson.

Tramways and Light Railways Association.—The *Official Circular* for August contains Mr. J. H Rider's paper on "Charges for Supply from Combined Lighting and Traction Stations," and the text of the Bill introduced into Parliament last session by the Hon. Arthur Stanley (president of the association) "to provide for the establishment of a highway commission for England and Wales, and for the amendment of the laws relating to highways and bridges in England and Wales, and for other purposes" It is expected that the measure will be brought up again next session.

Michigan School of Mines—We have received the year-book of this institution for 1904-5, from which we observe that the college continues to do good work in providing tuition in civil, mechanical, electrical, and mining engineering. Although the larger proportion of the students belong to the State itself, it is open to those all over the Union, and, in fact, to those of other countries, England being a contributor to its roll, which numbers over 220. The year-book is accompanied by a collection of picturesque views illustrating the various buildings and laboratories of the college.

A Use for Arc Lamp Carbon Ends.—An economical method of using up arc lamp carbon ends is described by L. Bernard in the *Elektrotechnische Zeitschrift*. It consists in cementing several ends together so as to form a single long carbon. The cementing is carried out by cutting the ends of the pieces so as to allow them to fit together, covering these ends with a paste made of water glass and powdered carbon, and then lightly pressing the pieces together. Such made-up carbons were found to be satisfactory in every way. They burnt, both with direct and alternating currents, just as well as new carbons, even at the junctures. Tests proved that the resistance was but little greater than that of new carbons, whilst as regards mechanical strength the made-up carbons, when subjected to a uniform stress, were found, if anything, more liable to break between joints than at the joints.

Engineering and the Army.—Hitherto it has been rather the fashion to regard the engineering arm of the national forces as merely auxiliary to the combatant ranks, but the Russo-Japanese war has served to emphasise the primary importance of this branch of the services, especially for field work, such as telephony. In view of this the Army Council has decided to move the depôt and training Battalion of the Royal Engineers from Rochester to Tidworth, and the School of Military Engineering will be stationed on Salisbury Plain, where adequate accommodation for training will be available. The organisation of the corps mentioned is to be readjusted, as between the fortress, field, and telegraph units, so as to fulfil the latest developments of latter-day warfare. The abolition of submarine mining has liberated a number of sappers, many of whom will be absorbed by the new searchlight companies about to be created. It looks as though this time the military authorities realise the need of adaption to modern conditions.

A Combination Accident.—A curious combination of accidents is described in the *Scientific American*. At an opening of one of the bridges over the Milwaukee River a large and heavy street car was just leaving the swing-bridge over this river, and its forward truck was on the abutment when a steamer, through some misapprehension, ran into the opposite end of the bridge. The result was to turn the bridge on the turn-table, and to move it round until the street car almost fell into the river. The car broke the end truss of the bridge, causing the floor to drop, which further imperilled the street car. The street railway company immediately made the necessary arrangements to place the car back on the track, and this they did by floating a scow beneath the car and building up a mass of blocking, by means of which the car was jacked up and run on to the tracks on shore. A fortunate feature of the accident was that no lives were lost, and that all the passengers made their immediate escape. The forward set of trucks remained on the abutment, but the after set fell into the river when the floor of the bridge collapsed.

Electrical Progress in Ceylon.—From our contemporary *Indian Engineering* we gather that the annual report for 1904 of Mr. A. S. Barnard, the consulting electrical engineer to the Ceylon Government, is again a record of multifarious duties performed. Certain of these are scarcely of an electrical nature, such as serving on a condensed stores committee, but others include inspection of electricity meters, and the preparation of various lighting schemes for hospitals and Government buildings. The Nuwera Eliya telephone scheme is again postponed owing to lack of funds, but a proposal to erect a generating station and to supply electricity for public and private lighting at this popular hill station is under consideration. The estimates under this heading involve an initial outlay of Rs.112,000 (about £7,500), and an annual expenditure on street-lighting of Rs.5,629 (about £375). In Kandy, the complaints of too poor a pressure of supply have been checked by the laying of more underground mains and feeders. In Colombo there have been troubles in the Fort area through storms and lightning, but no interruption in the Cinnamon Gardens district. New lifeguards, of the trigger pattern, are to be attached to some of the cars on the Colombo tramways, and the whole of the track is to be relaid with considerably heavier sections of rails.

British Association.—The visit of the association to South Africa is likely to bear fruit in the way of cementing the link between scientists at home and those in our Colonies. The president announced, at the conclusion of his address, that a movement is on foot to found a medal for South African students, and it is expected that a definite scheme will be formulated before the visit closes In this connection it is interesting to note some remarks by Sir Richard Jebb in a supplementary address. The eminent educationist remarked that South Africa had experienced great difficulties in regard to higher education, but a great advance was now being made. Dealing specially with the technical side of education, Sir Richard outlined a scheme, which will probably come into operation at an early date, for organising a university having faculties in engineering and mining, law, agriculture, and general education. This project is a welcome sign that the great engineering needs of the Colony are to be provided for by the establishment of a native technological foundation. On the arrival of the party at Pretoria they were entertained by Sir Arthur Lawley, who saw in the efforts of the association the means of developing the great industries of the South African continent, for, as Sir Arthur remarked, it was at the shrine of that wonderful oracle Science that inspiration for this purpose should be sought.

Electricity and Therapeutics. — A congress of physical therapeutics was held at Liége on Aug. 12-15. The meeting was well attended, and numerous papers were presented. Among the latter we observe that the subjects included the physiological effects of static electricity, high frequency, and radiotherapy. This is a gratifying token that the prejudice formerly entertained by many of the medical profession towards electro-therapeutics is giving way at least to tolerance. At the same time, the following sentences from our contemporary, the *Lancet*, seem to indicate that the attitude of the profession towards lay electricians, to which we have referred in previous issues, has not undergone any change for the better. Thus: "It is probable that the movement set on foot at this first congress will in time lead to the rescuing of all branches of physical therapeutics from the hands of empirics, and of establishing them on a firm scientific basis in the hands of medical men. The feeling in this direction was very strongly implied in all the sectional meetings." As the feeling was "very strongly implied" in all the sectional meetings, the inference is that those outside medicos who engage in electro-therapeutics are included among the "empirics" against whom the promised crusade is directed. To expel the charlatan is a highly desirable aim, but who is there that is competent to administer electricity if an electrician is not? This does not infringe upon the strict function of the physician, and the somewhat narrow-minded attitude of the latter is scarcely worthy of a great profession.

Japanese Customs Tariff.—The events of the last few days have attracted attention to the commercial developments that may be expected in the Far East with the cessation of the war, and in this connection it is of interest to note the tenor of the customs tariff lately compiled by the Japanese Government, which became operative on July 1. This provides that the dutiable value of imported articles shall be their actual cost "at the place of purchase, production, or fabrication," with the addition of packing, transportation, insurance, and all other charges up to the arrival of the articles at the port of disembarkation. In the event of an article coming under more than one rate of duty, it shall be assessed according to the highest rate. There is also a schedule of varying rates, in accordance with a scheme of general and conventional duty. Those countries with whom Japan has a most-favoured-nation treaty are accorded the benefit of the lower, or "conventional," rate of duty. The following scale is of interest to the electrical industry: electric light apparatus or instruments, 10 per cent. *ad valorem*; telephones, 10 per cent.; telegraph wire (other than galvanised), 5 per cent. *ad valorem*; cars and carriages for street railways, 10 per cent. *ad valorem*; submarine telegraphic cables, and underground telegraphic lines or cables, 10 per cent. Many articles are subject to an additional war tax, to remain in force for a year after the cessation of hostilities; but countries participating in the most-favoured-nation treatment are exempt from this, provided that the goods are accompanied by a certificate of origin.

"The Physical Review."—The September number of the *Physical Review* contains a number of articles which are of electrical interest, but which concern rather the scientist than the commercial man. Amongst these is one on "Billitzer's Method for Determining Absolute Potential Differences," by H. M. Goodwin and Robert B. Sosman. In this experiments are described on the Billitzer method of determining the absolute potential difference between a metal and a liquid, which, however, do not confirm the accuracy of the method. The results obtained by it, while agreeing more or less amongst themselves, differ largely from the potentials measured by other methods. Another article by Edward L. Nichols on the "Distribution of Energy in the Visible Spectrum," gives some valuable information as to the energy obtained from the various sources of light. The article on the "Evolution of Nitrogen from the Cathode and its Absorption by the Anode in Gases," by Clarence A. Skinner, is a continuation of experiments which were described in the July issue of the *Review*. In that case the evolution of hydrogen from various metals when used as cathodes in helium was described. In the present investigation nitrogen in conjunction with carbon electrodes was used. The observations showed that a vessel used as an anode also takes up nitrogen. The other articles in the issue are on the "Residual E.M.F. of the Carbon Arc," by G. G. Becknell, which is referred to elsewhere; "Some Physical Properties of Current Bearing Matter," by Paul R. Heyl; and on the "Variation of a Capacity with Temperature," by Earle M. Terry.

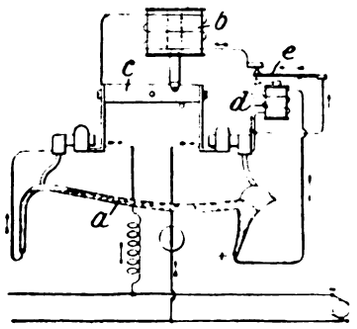
Personal.—A presentation of a set of silver was made last week by the staff and workmen of Messrs. Crompton and Co., Limited, to Mr. S. L. Brunton on the occasion of his resigning the position of works manager to that firm after a lengthy period of service. Mr. A. G. Hodgson, manager of the arc lamp and switch department, in voicing the sentiments of the staff, referred to Mr. Brunton's early services in building up the present Arc Works, which would remain a monument to his energy and ability. He testified from long personal experience to the kindly relations subsisting between Mr. Brunton and the staff generally—indeed, their late manager had been a friend as well as a chief. He had always had the interests of both masters and men at heart, and had invariably treated the staff with fairness. Messrs. P. G. Cheverton, W. Bickmore, and C. Perry, old members of the staff, added their meed of praise, the first-named defining Mr. Brunton's motto as "Know thy work and do it," after which Mr. Brunton was presented with the memento, which bore the inscription: "Presented to S. L. Brunton, Esq., as a token of esteem from the staff and workmen of the Arc Works, August, 1905." Mr. Brunton, who was received with loud cheers on his rising to acknowledge the gift, expressed pleasure at the cordial relations which had always existed between himself and the staff. He had been served loyally by everyone, and no grave difficulties had ever arisen. Both he and his wife and family would view the handsome present as a lasting token of their esteem. In conclusion, he wished every prosperity to the business, and trusted that there would be plenty of work to keep all employed continuously.

Commercial Intelligence.—The Board of Trade has issued a list of the members of the new Advisory Committee on Commercial Intelligence, their names being: Sir Frank Forbes Adam (Manchester), Lord Avebury, Sir Alfred Bateman, Sir Hugh Bell, Mr. H. Birchenough, Mr. T. F. Blackwell, Mr. H. Mitchell (Bradford), Mr. F. Brittain (Sheffield), Mr. T. Craig Brown, Mr. A. Wilson Fox (of the Board of Trade), Mr. C. A. Harris (of the Colonial Office), Mr. T. W. Holderness (India Office), Sir William Holland, M.P., Sir Francis Hopwood (Board of Trade), Mr. A. Bonar Law, M.P. (Board of Trade), Mr. Algernon Law (Foreign Office), Mr. R L. Paterson, Sir Albert Rollit, M.P., Mr. H. Llewellyn Smith (Board of Trade), Lord Strathcona, and Mr. D. A. Thomas, M.P., with three others not yet appointed, who are to represent South Africa, Australia, and New Zealand. The President of the Board of Trade will be chairman of the committee, and Mr. W. F. Wintour secretary to the committee. The period of five years for which the Advisory Committee on Commercial Intelligence was appointed in 1900 having terminated on May 24 last, the new committee is appointed for a further

Digitized by Google

period of three years to continue the work. The functions of this committee, subject to confirmation by Parliament of the Bill for the creation of Secretaries of State for Trade and Local Government, will be to "advise the Board of Trade on the work of their Commercial Intelligence Branch and on such matters relating to foreign tariffs and other commercial questions as the Board may refer to them; to improve the means of obtaining and diffusing information for the benefit of British trade by means of commercial missions and correspondents abroad and otherwise as they may think fit."

Mercury Vapour Lamps.—A patent has been granted to Mr. C. O. Bastian for a mercury or other luminous vapour electric lamp, to be started by tilting, which is so arranged that the liquid metal does not form a closed circuit through the lamp when this is inactive, the starting being effected by the operation of a shunt coil or other electrically-operated device. In the accompanying diagram, when current is supplied, the shunt coil, *b*, tilts a lever, *c*, carrying the lamp, *a*, in opposition to gravity, to cause the mercury to complete the circuit through the tube; a series electromagnet, *d*, then attracts an armature, *e*, to open the shunt circuit, so that the shunt coil, *b*, drops the lamp, the mercury divides, and the light is produced. The cut-out, *d*, *e*, may be dispensed with, and a series electromagnet may be provided to return the lamp after the shunt coil has acted. The lamp may be arranged so that the mercury is divided by a further movement of



the lamp after connection has been effected, instead of by a return movement. In order to add red or yellow light to the light given directly by the lamp, reflectors or reflecting surfaces near it are coated with rhodamine or other fluorescent material. The lamp may be enclosed in a chamber containing ammonia gas, or any other gas opaque to radiant heat, the chamber and the lamp being both sealed. The inventor mentions that the lamp may be of heat-resistant Jena glass, and the defective seals in this are not important if the outer chamber is of ordinary glass and sealed perfectly. A little air in the lamp facilitates starting.

Electrical Fire Risks.—The *Journal* of the Western Society of Engineers, published at Chicago, for June, contains a paper, by Mr. W. T. Benallack, on "Electrical Fire Hazard," a paper which was read before the electrical section of the society in the spring. The author has had many years' experience in inspecting electrical work on behalf of insurance companies, and hence his general conclusions on the subject are the outcome of practical knowledge. He blames, as other experts have blamed, the users of electric light and power for their desire to have work carried out on the cheapest possible lines. Frequently fires have been caused due to the purchaser insisting on using cheap and inferior materials against the advice of the electrical engineer installing the same. There is no doubt that fire insurance companies have done a great deal to raise the standard of electrical work, and that their inspections are by no means unfavourable to the electrical contractors as a whole. For instance, the author states that during 10 years he secured the rewiring of some 3,000 buildings where defects existed, and the conditions were similar to those that had caused serious fires in other localities. He also secured the adoption of the National electrical code in 11 of the larger towns within his district, who appointed municipal inspectors to supervise all electrical work. We do not propose here to refer to the illustrated burn-outs which are also described in the paper, as in many instances they are due to faults of a nature which are not likely to occur in this country. We agree with the author that many large fires have been written up in the daily papers as due to electrical wiring, when investigation has proved that electricity had nothing whatever to do with the outbreak. Such loss as there is when considered in conjunction with figures for other illuminants prove that electrical distribution, if well designed and carefully executed, provides a smaller fire hazard than any other means of lighting.

The Victoria Falls.—The consideration by the Engineering Section of the British Association of the problem of harnessing the Victoria Falls was initiated by Mr. Robert Hammond, who read a paper entitled "Electric Power Distribution for the Rand," the following extract from which, reproduced from the *Times*, is interesting: "There were no engineering difficulties in the way of supplying electrical energy to all the mines on the Rand from a central power-house utilising the Victoria Falls, but the cost would far outweigh the annual outlay on coal. He sketched in detail a more economical scheme for distributing power by burning coal nearer the Rand. He estimated that they would be able to supply power at the rate of 0·7d. per unit, and he had little doubt that those now using steam power would find it economy to adopt electric power." The debate generally was in favour of this view, though Mr. Alexander Siemens contended that users could generate their electricity as cheaply as any central station could supply it. Prof. Ayrton reviewed the subject at considerable length, and it will be observed from the following remarks of his that the professor incidentally figured in the *rôle* of æsthete: "The pioneering development which American enterprise had brought about, combined with the extraordinary commercial success which electric power distribution had won on both sides of the Atlantic, made people ask, 'Is such an industrial revolution in store for South Africa?' At first sight the answer was 'No,' in view of the fact that coal-fields blackened the map, and the produce of some was reported to be nearly equal to the best Welsh. On the other hand, he pointed to the experience of South Wales and Tyneside, where electric power was now largely utilised. Considering the possibilities of Victoria Falls, and contrasting them with Niagara, he stated that the water which was utilised, and which would ultimately cease to pass over Niagara, would be nearly five times as large as the total amount passing over the Victoria Falls at the present moment. A convenient spot for a power station was at the end of the second gorge, but he advised them jealously to guard the beauty of the falls. While he advocated the electric transmission of power, he thought they should not start by constructing a transmission line from the falls to Johannesburg, not because it was unworkable, but because there was not yet sufficient demand for power along the route." This latter objection is one that often confronts the pioneer of power supply, but with the anticipated industrial expansion of South Africa it may disappear in the not distant future.

A Safety Device for Telephone Lines.—As a safeguard against damage to telephone users through

Digitized by Google

excessive acoustical effects produced by atmospheric discharges, Herr H. Steidle suggested, and has recently tried, a special form of coherer connected across the telephone terminals. In attempting to make the decohering after a discharge automatic, however, several difficulties were met with, and an improved type of rotating coherer (described in the *Elektrotechnische Zeitschrift*) is now employed. This consists of a steel disc, *s* (Fig. 1) kept in continuous rotation by means of a small electromotor. Two German-silver springs, f_1 f_2, press lightly against the highly-polished sides of this disc, and a small cushion, P_1, with a wick, D, dipping into an oil-well, provides the necessary lubrication. The telephone to be protected is connected across the terminals, K_1 and K_2. The variation of the resistance of

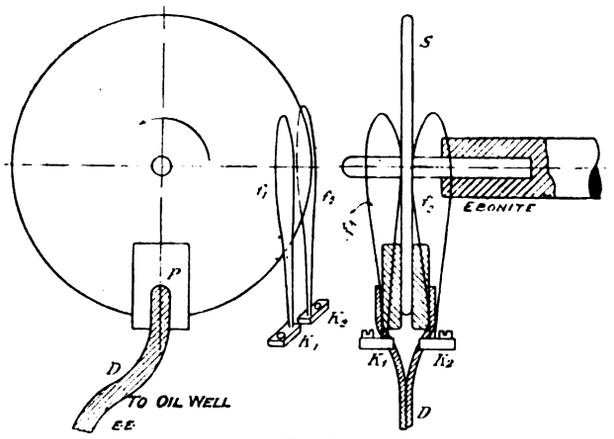


FIG. 1.

the apparatus with the voltage applied is shown in Fig. 2 This test was made after the disc had been running at the best speed—about 1,000 r.p.m.—for many hours. As soon as the disc came to rest, the resistance sank to a few ohms, but reached its original high value again immediately the rotation was restarted. The pressure of each spring against the disc was about 10 grm. The effectiveness of

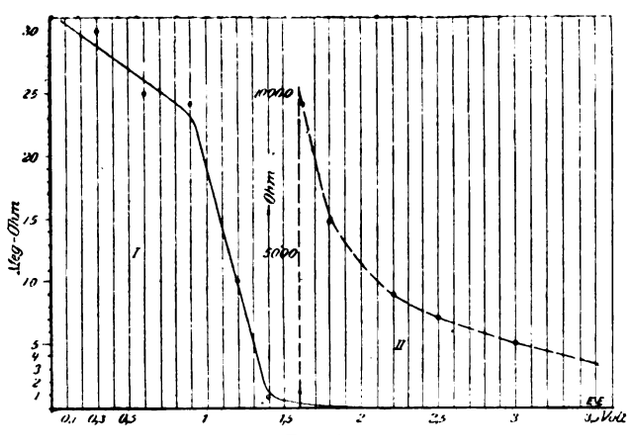

FIG. 2.

the arrangement is readily proved by discharging a condenser between the terminals, K_1 K_2. This produces a hardly noticeable effect on the telephone when the safety device is in use, although without it the noise produced by the same discharge is almost intolerable. Since decohering takes place instantaneously after a discharge, a telephone conversation can be carried on with practically no interference from such condenser discharges.

North-East Coast Institution.—The *Transactions* of the North-East Coast Institution of Engineers and Shipbuilders issued this last week contain the report of the closing meetings of the past session. In it the paper on "Boiler Furnaces and the Effect of Oil on their Ultimate Strength," by D. B. Morison, is reproduced, with the discussion on the same and the author's reply. In the same volume is given Mr. J. F. C. Snell's reply to the discussion on his paper on "The Application of Electricity to Industrial Purposes." In the course of this reply Mr. Snell had to deal with several speakers who had criticised both his figures of cost and also those for working isolated plants for electrical driving. He agreed with one speaker that the figures he gave in his paper as to the first cost per kilowatt for power stations might be too high. It is the concentration of power into one large station which enables the maximum reduction to be made in the capital expenditure per unit of plant. In reply to the remarks of Mr. W. A. Mountain, Mr. Snell adhered to his figures as to the first cost of small plants for the private supply of power, which was from £12 to £15 per kilowatt. Mr. Mountain's figure, as given in an estimate, was £45 per kilowatt. The discrepancy between these two is explained by differences of opinion as to how much spare plant is needed. Individual items of cost as given in the latter estimate are also disputed by Mr. Snell. On the ground of cost of production the author was also strongly criticised. For instance, Mr. Mountain said that in the Rhondda Valley, including interest and depreciation, the cost per unit generated was 0·4d., and in a small colliery near Newcastle the price was 0·45d., and that for a small installation of only 124 kw. As against these Mr. Snell gives figures from a colliery where a three-phase plant of 100-kw. capacity is used. The load factor is 66 per cent. and the cost per unit 0·726d. These latter figures agree fairly closely with the curves given in the paper, and show that Mr. Mountain's item for cost is either incorrect or phenominally low. The last part of the reply is devoted to support of the different charges made to consumers within the Sunderland area. Mr. Snell points out that it is the variation in the load factor of the consumer which accounts for the difference in the price per unit, and not the magnitude of the maximum load. He also, in reply to one speaker asking some information as to the power factor and load factor of a shipbuilding yard, states that in one particular yard within the Sunderland area there were 837 kw. of motors installed. The power factor was found to be 71 per cent. and the load factor 47 per cent. With the copy of the *Transactions* above referred to, Mr. John Duckitt, the secretary of the society, has forwarded to us a list of the subjects on which original papers would be acceptable for discussion during the forthcoming session. This commences in October next, and amongst the subjects we find the following, which deal more or less closely with electrical engineering: "Electric Wiring of Ships"; "Application of Electricity to Auxiliary Machinery in Steamers"; "Calorific Value of Coal and Oil Fuel from Various Districts and Countries"; Economies effected in the Consumption of Fuel during the last 20 Years"; "Electric Motive Power for driving Machinery in Shipyards and Engine Works"; "Overhead Travelling Cranes (Electric or otherwise)".

Two-Phase Service from a Three-Phase System—A method of utilising a four-wire three-phase system for rendering 400-volt two-phase service in case of emergency is described by Mr. H. B. Gear, of Chicago, in the "Wrinkles" department of the National Electric Light Association. The load was approximately 400 kilovolt-amperes, and to accomplish the desired transformation resort was had to eight 50-kw. standard lighting converters, four of which had a ratio of 10 to 1, with 208-volt secondaries, and the other four a ratio of 9 to 1, with 230-volt secondaries. Following the Scott system of transformation from three-phase to two-phase, the scheme of connections was worked out on the basis of using two transformers in series on both primary and secondary. The

Digitized by Google

normal primary voltage being 2,080 from neutral to either phase wire and 3,600 between the phase wires, it was necessary to employ two 2,080 volt windings in series on the primary side. The voltage of the motors being 400, it was likewise necessary to connect the secondaries in series. In order to secure approximately 400 volts on each of the secondary phases, it was necessary that the primary pressure should be about 4,160. The pressure was obtained by inserting boosters in the three-phase line. Voltmeter readings, taken without load, indicated unequal pressures on the transformers, and upon attempting to start a 5-h.p. motor the voltage on the vertical phase receded almost to zero, whilst that on the horizontal phase was but little changed. On connecting a separate transformer to the three-phase wires, it was found impossible to render any service with this scheme of connections. A theoretical analysis of the trouble suggested that the current which passed from the intermediate phase to the other two was choked by the impedance of the two transformers connected between the two outer phases, due to the fact that their windings were not in the same magnetic circuit. It was, therefore, found necessary to adopt the scheme of connections shown in the large diagram (Fig. 1), which we

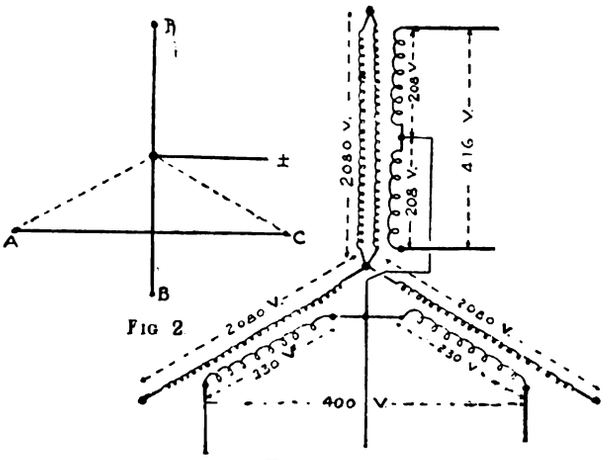

FIG 2

FIG 1.

reproduce from the *Western Electrician* of Chicago. The two 10-to-1 transformers were connected in parallel from the intermediate phase to the neutral wire of the four-wire line, and the two 9 to-1 transformers were connected from the two outer phases respectively to the neutral. The secondaries of the intermediate phase transformers were put in series to obtain 400 volts, and the 230 volt secondaries of the other two were combined in a similar manner. This scheme, however, unbalanced the three phase line, for while the current in the two outer phases showed 57 7 amperes, that in the intermediate one showed 100 amperes. Meters for 440-volt service not being available, the mid-points of the two-phase windings were tied together, as shown in Fig. 2, and the secondary neutral thus formed was used as a pressure wire for the meters. Two sets, consisting of four 50-kw. transformers each, were connected as shown in Fig. 2 to carry the load, and thus the desired result was accomplished.

Electricity Supply as a Business—There is no doubt that the reason why a considerable number of electrical undertakings in this country have not been more successful financially is the want of business-like management on the part of the engineers. They have failed to recognise that it is useless to spend all their time in increasing the economy of the generating plant if the load is not at the same time an increasing one. It is the engineer who is able to induce the consumer to take a supply of power and light, and at the same time keep his works properly equipped to meet the demand, who will succeed in the electrical supply business. Quite a number of the corporation undertakings now issue useful information to intending consumers. From Ipswich we recently received samples of literature which Mr. Frank Ayton, the engineer of the undertaking, is circulating. One of these gives nine good reasons "why you should use the electric light." The first three read as follows: "(1) Because it is the only method of lighting which makes it possible for you to always maintain fresh air in your rooms. It does not consume any of the oxygen in the air, neither does it heat the latter. It does not give off any fumes. These advantages, from the health point of view, are of enormous value. (2) Because it is the safest form of illuminant known. Its use greatly reduces the risk of fire, and there is no danger to life by leakage. The Phœnix Fire Office says: 'The electric light is, in the opinion of the Phœnix Fire Office, the safest of all illuminants, and preferable to any other, when the installation has been thoroughly well put up to its satisfaction, and the particular system employed has its approval.' (3) Because it is so extremely convenient. Directly you open the door you can light up the room by mere turn of the switch. There is no waste as with gas, since the lamps, being so easily lighted, are always turned off when leaving the room. When desired, as for instance, in nurseries, sick rooms and bedrooms, special turn-down lamps can be used." The remaining six reasons are also valid ones quite apart from the question of cost. Such a pamphlet will do much to popularise electric lighting. The second one, on electric power and what it costs, is equally serviceable. For instance, some actual results are given as to what has been attained by the adoption of electrical driving. At the National Arms Factory at Liége all the main lines of shafting are done away with, and instead short straight lengths of shafting driven by independent electric motors. As a result the power required per rifle turned out is less than half that in any similar factory using mechanical transmission from steam-engines—viz, 1½ h.p. per rifle against 3½ h.p. The wording of the result leaves something to be desired, as the statement that it takes 1½ h.p. per rifle neglects the important element of time. Again, it is shown that the coal bill at the Royal Arms Factory at Liége was reduced to one-third by the adoption of electric motors throughout the factory. Several other instances are given, and the pamphlet ends as follows: "What is the reasonable deduction to be made from the above statements? It is this: if these large firms, previously producing power on a large scale by steam and gas engines, could make such considerable savings by adopting electric driving, then you — working on a much smaller scale—will derive, in proportion, a much greater benefit, simply because it now costs you considerably more to produce a unit of power by your present methods than it cost them with their previous methods, the general rule being that the larger the scale of operations the lower the cost of producing the unit of power. If you change to electric driving you can buy power from the Corporation supply at prices which are among the lowest and most favourable in the country—2d. down to 1½d. per unit, which works out at 1½d. down to $1\frac{1}{10}$d. per electrical horse-power per hour. Let us have the opportunity of going into the matter with you—it won't be a waste of your time, and we can put absolutely convincing figures before you.' Ipswich is to be congratulated on the clear way in which the advantages of their municipal electrical supply is being put before the inhabitants. The idea of publishing the actual yearly accounts which users of electric motors have had to pay at Ipswich is also a good one, and will convince certain classes who do not trouble to read literature for which they have not to pay.

THE YORKSHIRE ELECTRIC POWER COMPANY.

This company, as mentioned in a recent issue, has commenced the supply of power from its Thornhill generating station, and organised an electrical exhibition to show intending users of power what could be done by electric motors. The powers of the company to distribute electrical energy date from the 1901 session, and cover a very wide area (about 1,800 square miles) in the West Riding of the county of York. The chief manufacturing districts of the county are included, in which it is estimated that over 2,000,000 h.p. is actually employed, so that there is ample scope for electrification. Mr. Horace F. Parshall has designed the equipment of the power station, and acts as consulting engineer to the company. Mr. W. B. Woodhouse is the resident engineer, and to him we are indebted for the following facts as to the power station and the development of the demand for power. This last and most important branch of the scheme has been energetically pushed, and already a large number of consumers have been obtained. The diversity of uses helps the station to obtain an economical load, and hence we propose to describe in detail the various classes of consumers already secured. Thus the company are authorised to supply local authorities in bulk, and to make other agreements with them. Where the local authorities hold a provisional order for their district, the company may not supply in that district without the consent of the local authority. A number of local authorities have, however, realised that it is greatly to the advantage of the district to let the power company supply all large consumers direct, and in the cases of the Mirfield District Council and the

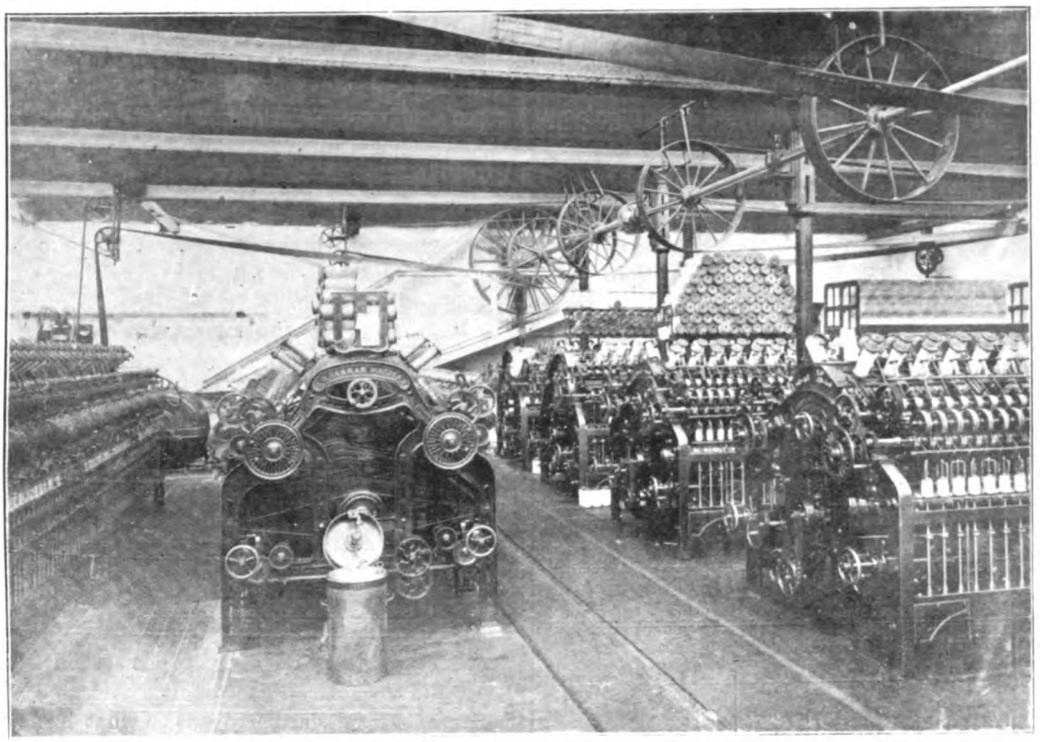

FIG. 1.—Electrically-Driven Roving Frames.

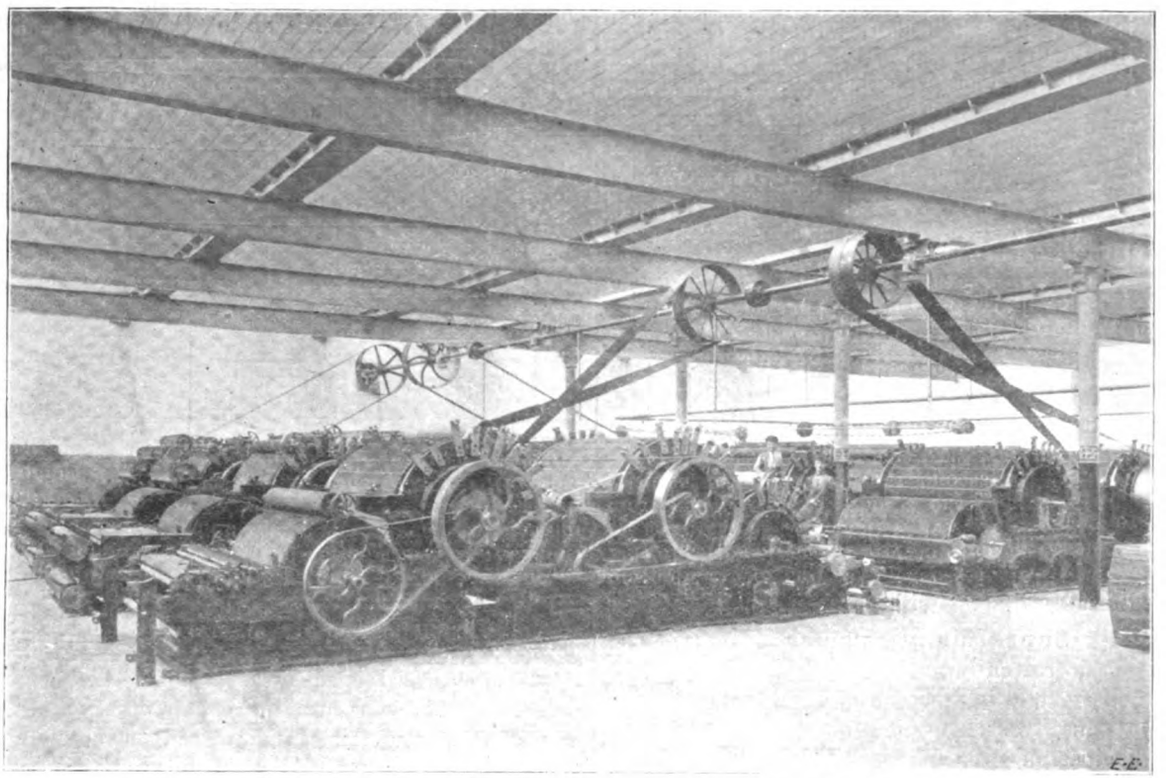

FIG. 2.—Carding Engines driven from the Yorkshire Power Company's mains.

Digitized by Google

Liversedge District Council, who are taking a bulk supply for distribution for lighting and small power users, the company are supplying the large users direct. The Pudsey Corporation, who are taking a bulk supply for lighting, power, and tramways, have also consented to the company supplying in the case of one large user—namely, the woollen mills of Messrs. Wm. Lupton and Co.—they preferring to give consent for each individual case on its merits.

At Liversedge it is interesting to note that the Council have already a refuse destructor in existence, but after a

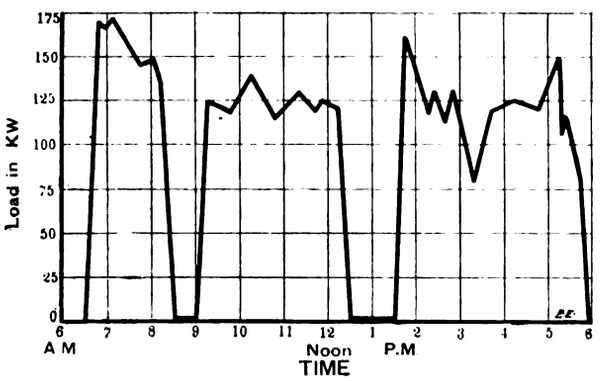

FIG. 3.—Day Load Curve from a Textile Mill supplied by the Yorkshire Power Company.

very lengthy consideration of the matter they decided not to use this for the purpose of generating electricity, being somewhat guided in their decision by the report of the committee of the Corporation of Leeds, who recently considered this matter and decided that in Leeds also this principle should be upheld. The Liversedge Council have made an agreement to take a bulk supply for 25 years, and they propose to distribute three-phase current for power and single-phase for lighting. The system of tramways in their area will, of course, be supplied by direct current.

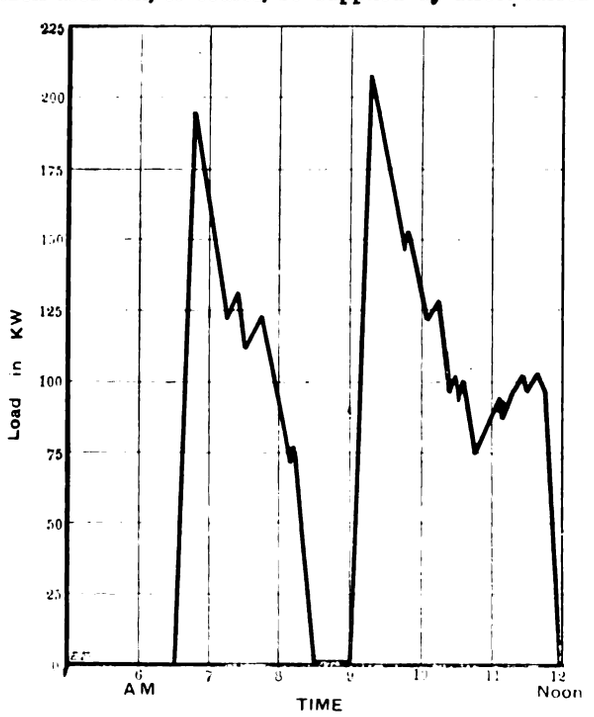

FIG. 4.—Saturday Morning Load Curve from the same mill.

The consulting engineers of the Council are Messrs. Charles Gott and Sons, of Bradford.

The Birstall District Council own their own gasworks, and were thus naturally inclined to consider favourably the driving of an electrical generating plant by gas-engines. The extremely disappointing results obtained in small gas-driven stations, when set against the terms on which the power company offer bulk supply, decided in favour of making an agreement with the power company. The consulting engineer to this Council (Mr. J. E. Ellis, of Morley) has decided on a single-phase distribution for lighting.

The Mirfield Council were the first to take a bulk supply from the company. This supply has now been given since the beginning of July, and connections to the Council's mains are increasing rapidly. The consulting engineer to the Council (Mr. A. B. Mountain, of Huddersfield) decided on an alternating-current supply, and lighting is given at 200 volts single-phase. The power company are supplying large power users direct with three-phase current.

The limitations of small generating stations and the cost of management of small undertakings is leading local authorities who have their own generating stations to consider favourably the company's proposals for a bulk supply, and the company is now negotiating with several local authorities who are in a position of having generating stations, and it is confidently anticipated that additional requirements will be met by a bulk supply from the company. In large districts such a supply is of great advantage, as the company can give a supply at outlying points, and so save considerable expenditure on feeders.

Power Consumers.—A large load is anticipated from collieries, as within a radius of eight miles from Thornhill power station there are 174 collieries. The company have

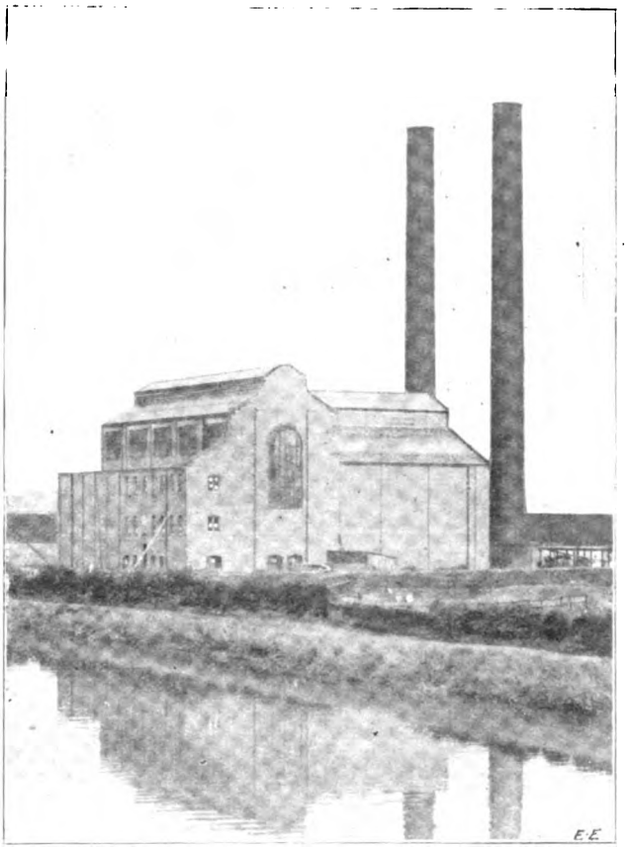

FIG. 5.—The Thornhill Power Station.

already made agreements with five collieries, and negotiations are proceeding with many more. The last few years have shown interesting and rapid developments in the application of electricity in mining work. The advent of the high-lift centrifugal pump has proved of great benefit to the collieries. These pumps are admirably suited for electrical driving, and their first cost is low compared to that of ram pumps. The Low Moor Company (one of the power company's consumers) is installing at their Three Nuns pit a centrifugal pump to lift water 175 yards. Coal-cutting by electricity is increasing year by year. From the point of view of safety, there is no doubt that the three-phase current from the company's mains should be used in collieries without conversion into direct current wherever possible. Where oil-break switches are used there is no risk of explosion when switching on and off. The makers of coal-cutting machinery are now nearly all prepared to supply cutters driven by three-phase motors, and it is anticipated that the future will see a much larger proportion of these machines in operation. The company, however, are prepared to supply direct current to collieries who have existing plants, and this is being done in the case of the Calder pit of the Mirfield Coal Company, where coal-cutting, pumping, and hauling are being performed

Digitized by Google

electrically. The company have a special tariff for supplying collieries, or to any consumer who is prepared to take a limited supply—that is to say, any consumer who is prepared to guarantee that a certain percentage of his consumption shall be at night-time, that his maximum demand will be reduced between the hours of 4 and 8 p m., so as not to interfere with the lighting load.

of Gomersal. Other textile manufacturers taking a supply are Messrs Wm. Lupton and Co., of Pudsey, and Messrs. Booth Bros, of Drighlington. Figs. 1 and 2 show respectively some electrically-driven departments in the above mills.

The advantages of electrical driving of textile machinery are becoming more widely known, and the company expect to derive a large portion of their load from this source. It is often considered that the load of a mill engine is perfectly steady, but the actual records taken from a

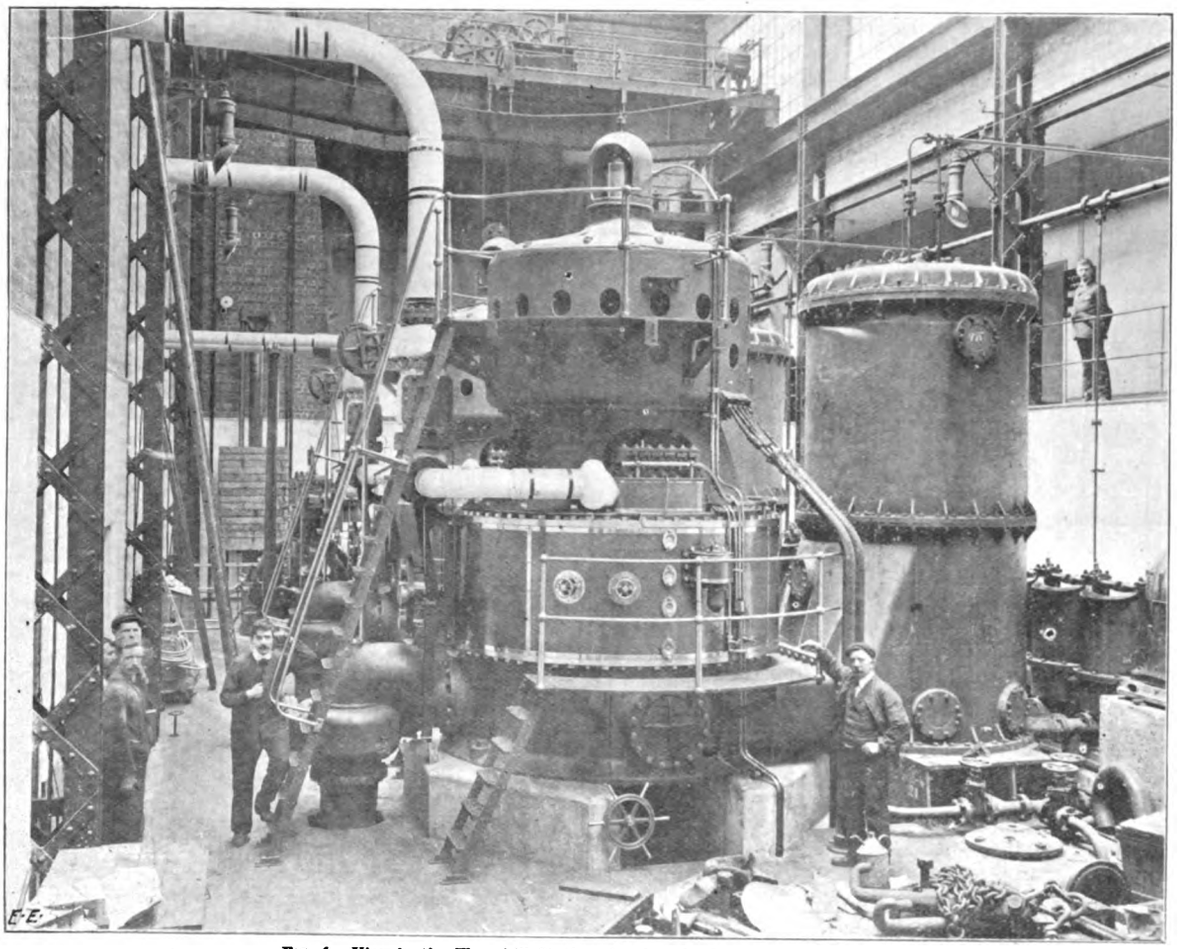

FIG. 6.—View in the Thornhill Station showing the 2,000-kw. Curtis Turbines.

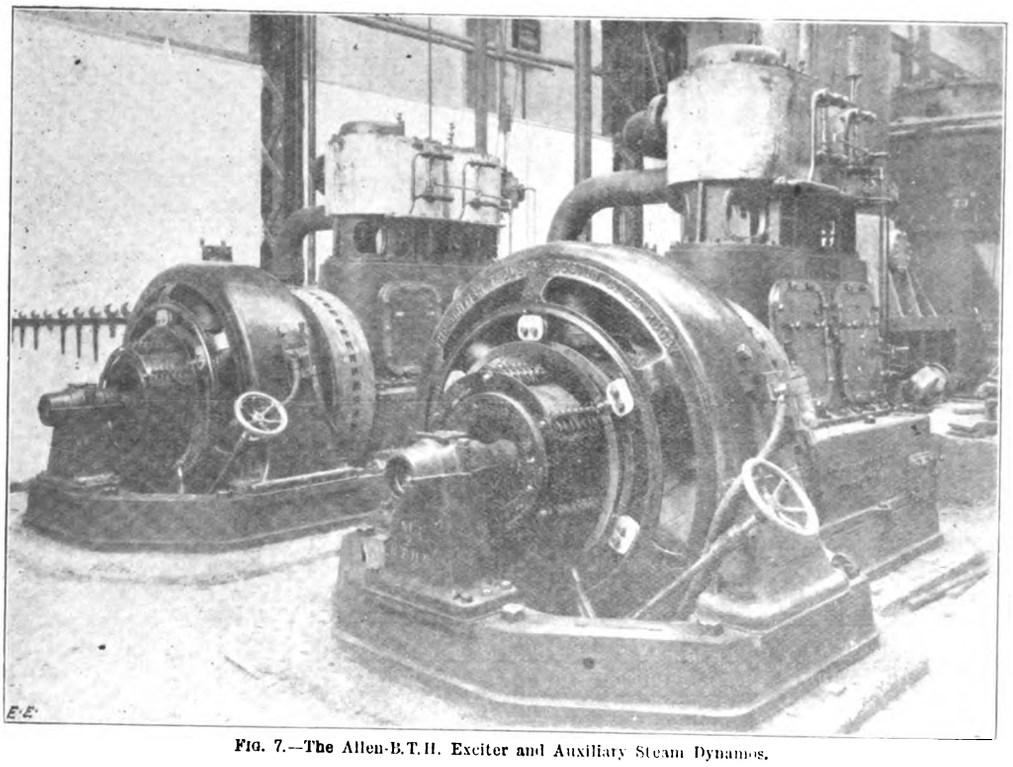

FIG. 7.—The Allen-B.T.H. Exciter and Auxiliary Steam Dynamos.

The company has the distinction of being the first to drive from public mains a complete textile mill—namely, the worsted spinning mill of Messrs. T. Burnley and Sons,

Digitized by Google

textile mill, reproduced in Fig. 3 and 4, are interesting, showing how the load varies. The increased power needed to start again after a meal hour is remarkable.

It is particularly interesting to note how the load dwindles on Saturday, the human element anticipating stopping time by some hours. It is of little value to give a list of the company's consumers, as this is being added to daily, but it may be mentioned that already four local authorities have made agreements—five collieries, three textile mills, two railway companies, and a number of other power users. The diversity factor of the company's consumption will be very large, and the load factor on the station correspondingly high.

The Thornhill power station (Fig. 5), from which these will be supplied, is situated between the L. and N.W. Railway Company's Ravensthorpe Station and the River Calder, the position being chosen with due regard to its proximity to a railway and water supply, as tending to keep the cost of working as low as possible. The station, as can be seen from the illustration, is a steel and brick structure divided into two parts—the boiler-house (70ft. by 80ft.), the engine-house (100ft. by 50ft.). The design of the station is such that the capital cost per kilowatt is reduced to a low figure without sacrificing security or efficiency in any way. Extensions will be made, as required, by adding to the present station (which is in itself two complete unit stations) similar "units" until a total capacity of some 60,000 h.p. is reached. Coal may reach the power station by road, rail, and river; by road the coal is delivered to a hopper outside the boiler-house, and is raised from there to the boiler-house bunkers by means of a bucket conveyor; the railway siding (not yet constructed) will feed the same conveyor, which will raise 25 tons of coal an hour.

The coal bunkers at the top of the boiler-house are of steel, and from these coal is delivered through automatic measuring shoots to each boiler. Provision is made for six boilers, of which four are already installed. They are of the water-tube type, made by Babcock and Wilcox, each

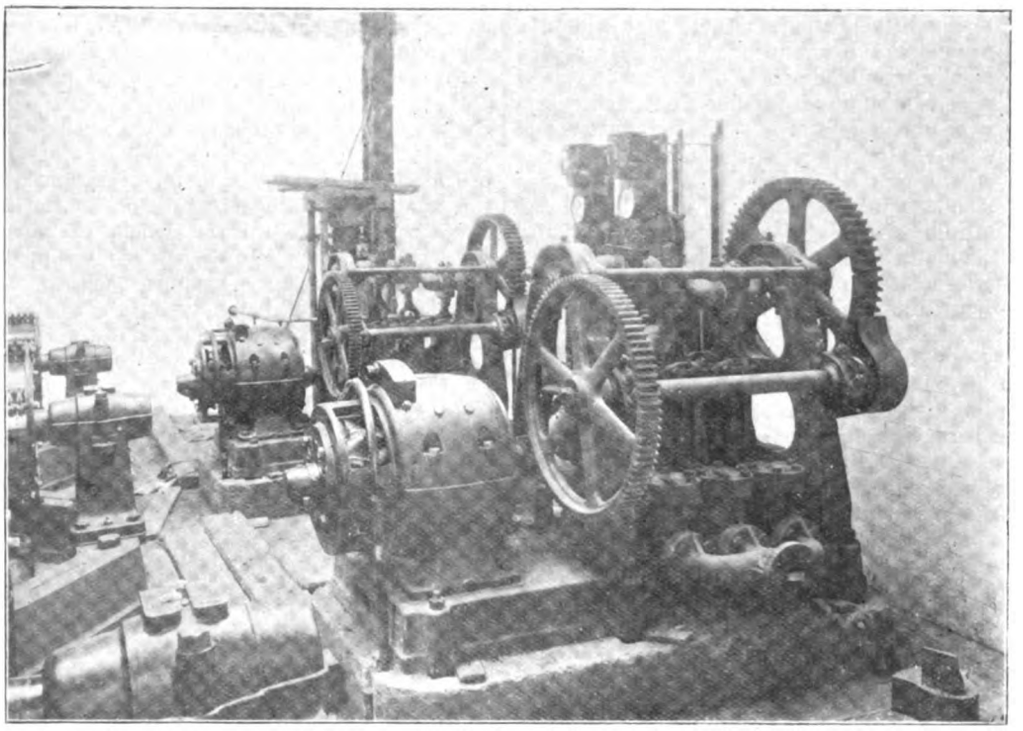

FIG. 8.—The Three-Throw Pumps supplying the water to the footstep bearing of the Curtis Turbines.

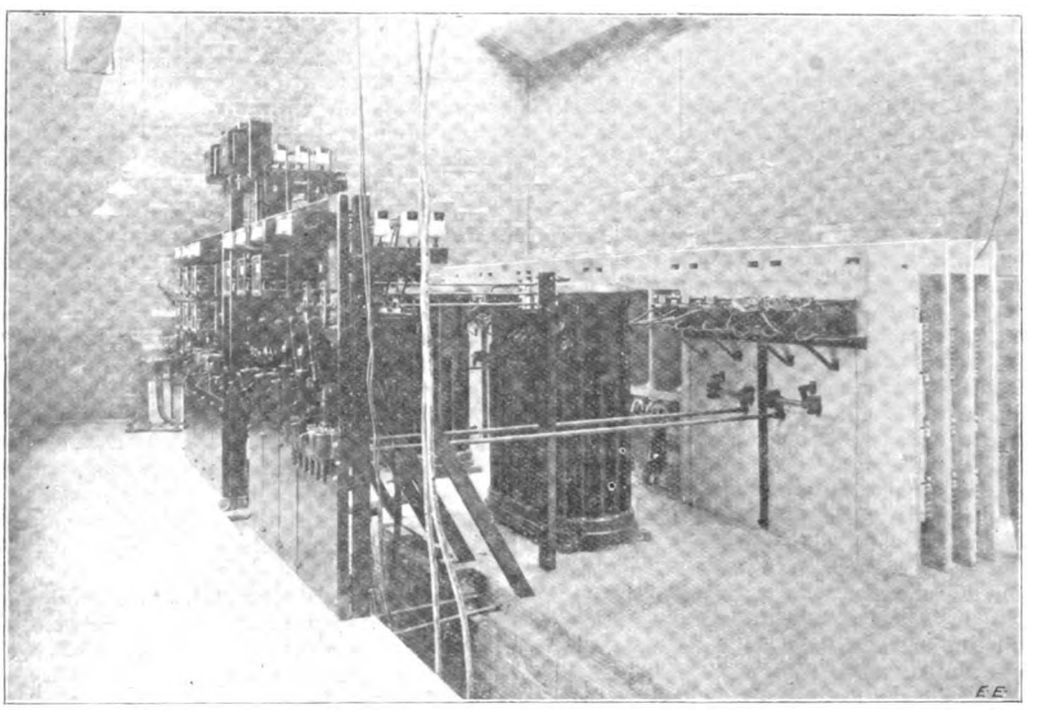

FIG. 9.—Interior of the Mirfield Sub-Station.

Digitized by Google

capable of evaporating 20,000lb. of water per hour from a temperature of 60deg. F. to steam at 160lb. per square inch pressure, and 150deg. F. superheat. Each boiler has a heating surface of 5,730 square feet and a grate area of 100 square feet. The chain grates and stoker gear are worked by electric motors. The ashes fall by gravity to the basement, and are delivered into trucks. The main flues, of which there are two, are beneath the boilers, and lead to two brick-lined steel chimneys 150ft. high and 10ft. diameter. The economical combustion of coal is watched with great care, daily tests being made of the heat value of the coal used, the composition of the flue gases, and everything bearing on the boiler efficiency. The arrangement of the steam and feed-water piping is designed so that one half of the boiler-house can be completely isolated from the other. At the end of the boiler-house are situated the feed pumps, hot-wells, and water-tank, immediately under the control of the boiler-house staff. These feed pumps are the only auxiliaries which are not electrically driven.

The engine-house, like the boiler-house, has a main floor and basement; it is designed to contain generating plant of 8,450 kw. (11,000 h.p.) capacity. Two turbo-alternators, each of 2,000 kw. (Fig. 6), are already installed, and a third is being erected. Three high-speed Allen engines direct connected to direct-current dynamos of 150 kw (Fig. 7) each are installed at the end of the engine-room; these machines provide the current necessary to operate the station motors and for a local supply. The main generating sets are Curtis turbo-alternators made by the British Thomson-Houston Company, of Rugby; they are unique amongst steam-turbines in having vertical shafts with the alternators mounted on top, an arrangement which enables a large amount of power to be housed in a small building. The shaft and all rotating parts are carried by a hydraulic footstep bearing. Water at a pressure of 400lb. to the square inch is supplied by three-throw motor-driven pumps (Fig. 8), and the shaft floats on a film of water. The top and centre bearings of these machines are lubricated by the gravity system, with oil at a pressure of 10lb. per square inch pumped from a settling tank in the basement into a tank at the top of the engine-house, from which it gravitates to the bearings and returns to the settling tank. These pumps, and, indeed, all the auxiliary machinery in the station, are excellent examples of the adaptability of electrical driving to varied uses. The turbine runs at a speed of 1,000 r.p.m., and is controlled by a centrifugal governor; this governor by an electrical controller operates small steam-valves opening or closing the passages to the steam nozzles as the load varies.

A separate surface condenser is provided for each turbine, and the general arrangement presents some novel points; the condenser tubes are vertical, the air-pump running at 160 r.p.m. is direct coupled to a motor, and the circulating water discharge pipe being submerged at its end in the river allows the siphon action of the arrangement to be taken advantage of, and thus reduces very considerably the head against which the water is pumped. The siphon action is maintained by means of a dry-air pump which prevents an accumulation of air in the pipes and condensers. The centrifugal circulating pumps in the basement are controlled from the main floor; each pump is rated to lift 160,000 gallons per hour against a head of 28ft.

The proportionately large size of the condensing plant is on account of the benefits to be obtained by working with a high degree of vacuum in connection with steam-turbines; the results obtained with the present plant point to an extremely low consumption of steam per kilowatt-hour. Thus a steam-consumption test of one of the turbo-alternators was taken on April 26 and 27 this year, when the following results were obtained: With dry steam at 150lb. pressure and 28in. vacuum—full load, steam consumption 19lb. per kilowatt-hour; three-quarter load, 19·8lb.; half load, 21·8lb.; and quarter load, 25·6lb. per kilowatt-hour. With the higher superheat of 200deg. F. and 28in. vacuum, the above figures were reduced as follows: full load, steam consumption 16lb. per kilowatt-hour; three-quarter load, 16·6lb.; half load, 18·2lb.; and quarter load, 21·2lb. per kilowatt-hour.

An electrically-operated travelling crane travels the whole length of the engine-house; it is equipped with three motors, one for each motion. The alternators attached to the turbines generate three-phase alternating current at 10,000 volts, at which pressure it is transmitted to the various sub-stations. The switchgear controlling the machines and transmission mains, which is constructed by the British Thomson-Houston Company, is of a type that experience has proved suitable to controlling large powers at high voltages. It occupies three floors of one side of the engine-house, and is thoroughly fireproof. Each part is separated from the remainder by a brickwork partition, and can be disconnected when required without affecting the working of the other parts. The large amount of space occupied by the switchgear and considerations of safety call for a central control of all operations; there is, therefore, a control switchboard situated on the switch gallery. From this switchboard the whole of the main switchgear is operated by means of low-pressure current. All the high-pressure gear is enclosed, and the main switches, of the oil-break type, are worked by means of small motors. The switchboard attendant, on closing a small switch, causes the motor to open or close the main switch; directly the operation is performed the motor stops automatically, and a lamp lights up, informing the attendant of the fact. The paralleling of the alternators is also performed on the control board, the speed of the turbines being regulated by a small switch operating a motor attached to the governing gear of the turbine. The general type of the switchgear and control is similar to that used in the Lots-road station of the District Railway, and described in detail in our issue for Feb. 10, 1905. No high-pressure current is brought near the control board, the instruments showing the pressure and current in each feeder are all controlled by low-pressure current, and the maximum of convenience and safety is obtained. The switchgear for the direct-current machinery is also on the switch gallery.

System of Mains and Distribution.—The company's system of extra high-pressure mains is laid out with a view to giving a duplicate supply to every large consumer. This supply is at 10,000 volts, and the company's system is notable for the extreme simplicity of the switching arrangements. The protective devices are fitted to the cables in the power station; such complications as time-limit and reverse-current relays have been avoided. The system of mains is practically equivalent to a low-tension distribution network, except that it is in duplicate. Sub stations have been erected every four miles, and from these sub-stations distribution is effected at 2,000 volts within a radius of two miles. The majority of the company's power users are supplied at 2,000 volts, but in any extremely dense districts the company propose putting down a small amount of 400-volt distribution. Sub-stations are now erected and in operation at the following places: Thornhill, Mirfield, Gomersal, and Pudsey; other sub-stations are in course of construction at Birstall, Soothill, and Liversedge. The high-pressure cables, which were supplied and laid by Callender's Cable and Construction Company, are led from the power station in earthenware ducts for a considerable distance until they diverge in different directions, when they are laid in wooden troughs. Each cable is covered by a lead sheath and steel wire armouring, and contains three copper conductors insulated from one another and from the sheath by paper insulation. The cables are tested to three times the working pressure, or 30,000 volts, before being laid.

Fig. 9 shows the equipment of the Mirfield sub-station, which is typical of those stations from which direct current has not to be distributed. In the other sub-stations, like those at Thornhill and Ravensthorpe, rotary converters are also installed. Where low-voltage three-phase distribution is arranged, the voltage is 400.

Mains are now laid in the following districts: Thornhill, Dewsbury, Soothill Nether, Ravensthorpe, Mirfield, Kirkheaton, Liversedge, Gomersal, Birkenshaw, Drighlington, Leeds, Pudsey, and they are being extended in every direction. A supply can be given in any district within 15 miles of Thornhill in a few months, and the company will be pleased to deal with inquiries from any part of their area.

Digitized by Google

The company through their resident engineer are advising intending consumers as to what can be done to secure the best economy from electric power. They have also arranged for the supply of motor and other electrical apparatus on the hire-purchase system.

ELECTRIC DRIVING OF TEXTILE MILLS.*

BY W. B. WOODHOUSE, ASSOC. MEMBER.

1. *Introductory.*—The reasons for the slow rate of adoption of the use of electrical machinery in textile factories in this country are not far to seek. The first is the lack of accurate knowledge as to the results to be obtained from electrical driving; the second, the absence, until recently, of a public supply of electrical energy at a reasonable price. The object of this paper is to state briefly the advantages of electrical driving, and to show that a clear knowledge of the advantages will modify very considerably the prevalent ideas as to the relative cost of driving by individual steam plants and by motors taking a supply from the mains of a power company or electricity works. That the advantages are truly existent may be realised from the extent of the adoption of electrical driving in other countries. On the Continent it is largely used in the woollen, cotton, and silk industries; in the United States, at the census of 1900, over 140,000 h.p. of electrical machinery was in use in cotton mills alone, and a considerable proportion are supplied with current from public mains.

2. *Variation of Load.*—The preparation of animal or vegetable fibres involves a very large number of operations, and owing to the delicate structure of the fibre the amount of work done on it in each machine is small. It is, therefore, readily understood that the power required to drive the machines unloaded is a large percentage of the total required. Mechanical transmission of power from a main engine to the various machines by means of ropes, belts, gearing, and shafting involves a steady loss of power, which

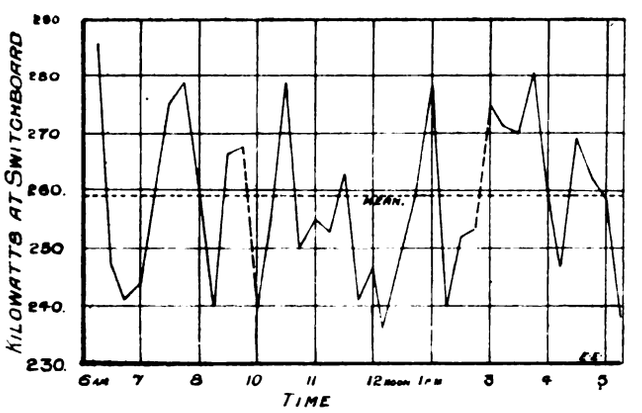

FIG 1. LOAD CURVE OF A FLAX MILL.

is very little reduced by the stoppage of individual machines. These facts have led many power users to believe that the load on the main engine is quite steady, and in comparing the cost of electrical with mechanical driving, on the basis of "horse-power hours," they are apt to find an advantage in mechanical driving that does not exist.

The efficiency of mechanical transmission in textile mills varies with each mill, depending as it does on the original design, the nature of any extensions which have been made, and the state in which the gearing is maintained. In a number of mills which the writer has tested, the average efficiency at full load is 50 per cent., the lowest 34 per cent., and the highest 70 per cent.; in all these cases the loss of power in the main engine being included. These losses, serious enough at full load, are practically constant, and so the efficiency rapidly decreases as the load becomes less. This steady loss in transmission has an important bearing on the variation of load on the main engine or source of power supply; in discussing this variation it will be convenient to speak of the ratio of the average power required to the maximum required during working hours as the working load factor—*i.e.*,

$$\frac{\text{Average power}}{\text{Maximum power}} = \text{working load factor.}$$

When the source of supply is electrical, this is equal to

$$\frac{\text{Units consumed}}{\text{Maximum demand in kilowatts} \times \text{working hours}}$$

Fig. 1 is an actual record showing how the load varies through the day in a flax mill of the British Linen Thread Company. The mill is electrically driven and the transmission loss small. The maximum power demanded is 285 kw. and the average 259 kw., giving a working load factor of 91 per cent. Had the various machines been driven by mechanical transmission from one main engine a steady extra loss would have been incurred, on account of the friction of extra shafting and gearing; assume this as only 20 per cent. of full load, then the maximum power would be raised to 342 kw., and the load factor increased to 92·5 per cent. That is to say, the more inefficient the

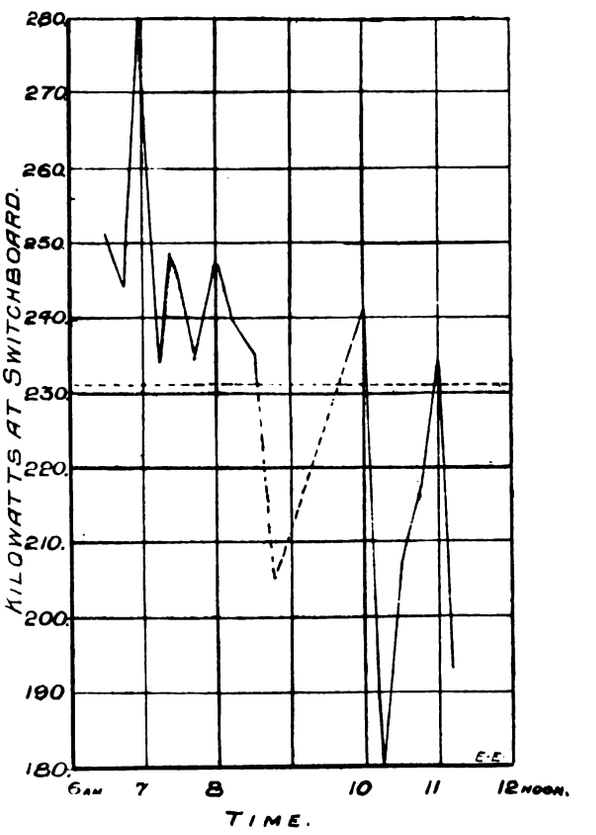

FIG 2:-LOAD CURVE OF A FLAX MILL.-SATURDAY.

system of power transmission in a mill, the steadier is the load on the main engine, and, though the useful power required varies in every mill, yet, with mechanical driving, the variation is masked by the steady loss in transmission. Fig. 2 shows the variation of load, of the same mill, on Saturday morning; the load factor here is only 82 per cent. In a large cotton mill the following variations of load were noted*: morning—maximum load 1,685 h.p. and minimum load 1,640 h.p.; afternoon—maximum load 1,635 h.p. and minimum load 1,575 h.p. Millowners usually reckon their costs in pounds per indicated horse-power per annum, and the figure is usually based on the maximum horse-power indicated; it is not possible to compare such a figure with the cost of electrically driving the same mill without knowing the electrical or brake horse-power taken to drive each machine, or group of machines, and the working load factor of the machines.

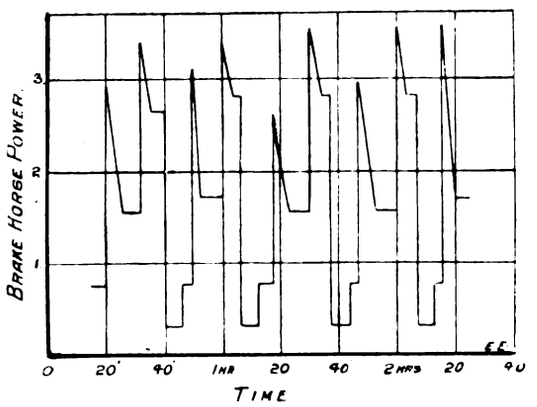
3. *Load Factor of Various Machines.*—In nearly every textile machine the starting effort is considerable—due to the inertia of the moving parts. In the "mechanical" mill starting a machine is usually accompanied by a slipping

* Paper read before the Leeds Local Section of the Institution of Electrical Engineers.

* "Centralisation of Power," by S. B. Paine.—British Association of Textile Managers, 1904.

Digitized by Google

of several belts and a general loss of speed. For each particular class of machines there are peculiarities of working which determine the working load factor, such as frequent stops of short duration, in the case of looms; a periodical stoppage of part of the machine, as in spinning; intermittent running, with long stops, as in milling or printing machines. A particularly irregular load is met with in the case of self-acting mules. Fig. 3 shows the power taken by a mule as it goes the various operations of drawing, twisting, backing off, and winding on. The working load factor is 46 per cent. on one machine. When a group of mules are driven from one motor a heavy fly-wheel on the motor tends to steady the demand for current; despite this, however, the fluctuation of load is more extreme than in the main engine of a mechanical



SELF-ACTING MULE-120 SPINDLES

FIG 3.—VARIATION OF LOAD—SELF ACTING MULE.

mill. Fig. 4 is part of a record showing the power taken by a motor driving four self-acting cotton mules. The maximum horse-power required was 32 b.h.p., and the average 19 b.h.p., or a working load factor of 59 per cent.

The variation in the amount of power taken by machines having many bearings, with temperature, is brought out in Fig. 5, which shows the power required to drive a cap spinning frame. It will be seen that as the bearings and the oil warm up the power steadily decreases. This is, of course, true for all machines, and may be described as the "Monday morning effect." The advantage of being able to see just what power a machine is taking under different conditions of working is a great point in favour of electrical driving. The following figures were obtained from a worsted spinning frame when two different qualities of spindle oil were used: oil A, 4·4 b.b.p average; oil B,

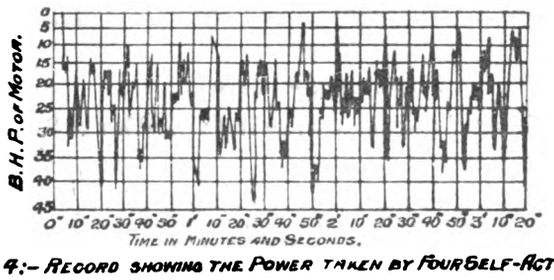


FIG 4.—RECORD SHOWING THE POWER TAKEN BY FOUR SELF-ACTING COTTON MULES WORKING TOGETHER.

4·19 b.h.p. average—or a difference of nearly 5 per cent. Where looms are driven in large groups the load is fairly constant, despite the frequent starting and stopping of individual looms, due to the large amount of shafting involved and the small power taken by each loom. In an "electrical" mill, however, a recording wattmeter will show the variations, and, more particularly, the tendency of the workers to start late and finish early.

The milling or fulling of woollen cloths is a process in which the power required varies from piece to piece, depending on the amount of milling required; the working load factor is very low. Fig. 6 is an actual record of a day's work of milling and washing machines; the working load factor is only 63 per cent. Tests made on carding machines show a fairly steady load during the time of running (Fig. 7). Rag-grinding machines often show a considerable variation, depending on the material they are being fed with. Fig. 8 is the load curve of two balling boxes, which are, normally, being repeatedly started and stopped.

4. *Power Absorbed by Various Machines.*—There is a lack of information as to the power taken by textile machines. The particulars of some tests are given below:

Spinning.—* Test made of a motor driving 38 ring spinning frames of 10,032 spindles, running at 9,000 r.p.m., spinning No. 35 cotton yarn:

Number of frames running	38	28	18	8
Power in kilowatts	140	107	76	44
Spindles per kilowatt	81·2	83 8	82·5	78·2

Or an average of 62 spindles per electrical horse-power.

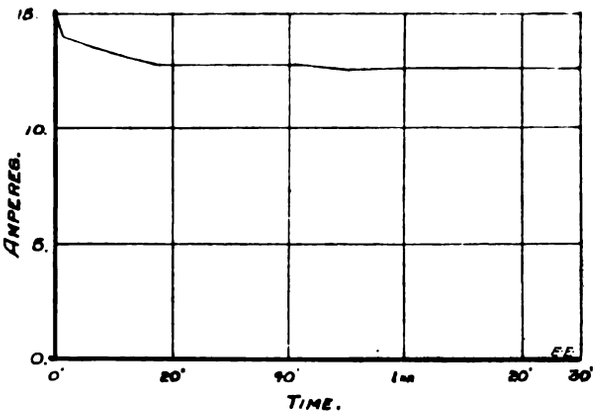
Tests made on worsted spinning frame of 200 spindles, running at 5,800 r.p.m.: First test—average brake horse-power, 4·45; second test—average brake horse-power, 4·19, the difference, as explained above, being due to the quality of oil used.

Self Acting Mules—Cotton.—† Test made on motor driving line shaft and four mules:

Mules running.	Spindles. Number.	R.P.M.	Maximum horse-power.	Average horse-power.
All	2 712	—	32	19
No. 1 only	672	7,600	20	13
No. 2 ,,	672	7,600	18	9
No. 3 ,,	684	7,800	15	9
No. 4 ,,	684	7,800	15	9

The result of tests made to determine the power taken by spindles at various speeds is shown in Fig. 9. It will be seen that the spindle friction and windage varies directly as the speed.

Roving Boxes—Worsted.—Dimensions of bobbins, 6in. by 3in.; number of spindles, 12; revolutions per minute, 1,000; brake horse-power, 0 4.



CAP SPINNING FRAME—NORMAL LOAD.

FIG 5.—SPINDLES AT 7,000 R.P.M.

Weaving.—The amount of power taken by looms varies with the class of work and dimensions of the looms. Silk looms—small loom, power taken 0·25 b.h.p. (authority, A. C. Eborall); jacquard, 0·5 b.h.p. Cotton looms—draper loom, 160 picks per minute, 0·25 (authority, de Wolf). Woollen looms—various, 0·3 to 0·5.

C. *Carding Machines.*—Woollen, carding botany—48in. swift: power at starting, 7 e.h.p.; running, average, 3·2. 60in. swift: running at 96 r.p.m.; average power, 5 e h p.

D. *Scouring Machine, or Leviathan.*—The dimensions of these machines vary considerably, and figures of horse-power taken are not of much value. The following figures of relative power taken are from a test of one machine: maximum running horse-power, 100 per cent.; when changing liquor, 38; working load factor, 86. The changing and heating of liquor reduces this to about 70 per cent.

Milling Woollen Cloths.—Test on motor driving milling machine, washing machine, and mangle: maximum electrical horse-power, 11; working load factor, 63 per cent. The amount of power taken in milling varies from day to day, depending on the nature and amount of milling required by the various cloths.

5. *Advantages of Electrical Driving.*—The advantages

* "An Electrically-Driven Cotton Mill," J. O' de Wolf.—New England Cotton Manufacturers' Association, 1902.

Digitized by Google

attendant on electrical driving are but partly gained if electrical transmission is adopted in the mill and the main engine or engines retained. The addition of a dynamo to the steam plant, and the replacement of mechanical transmission by electrical, in no way lessens the responsibility attached to the use of steam plant, nor does it relieve the manufacturer from keeping his eye on the coal market as well as on the textile. Now that a public supply of electrical energy is available throughout the manufacturing districts of Yorkshire and Lancashire at reasonable rates, manufacturers should not be slow to take advantage of it when once they realise the consequent benefits. Many of the advantages of a public supply are difficult to give an exact cash value to, but they are, nevertheless, very real. Briefly enumerated they are: (1) A saving in space, buildings, and capital expenditure. The manufacturer can employ his capital to greater advantage on productive machinery, and he is not compelled to decide beforehand what his requirements will be for 10 years ahead. (2) A reduction in fire risk, insurance, rents, rates and taxes, wages, repairs, and maintenance. (3) An absolute freedom from worry as to spare plant in case of a breakdown, or as to extensions or alterations. If an extra 100 h.p. is required temporarily, it can be drawn from the mains. If slack times come, the manufacturer can shut down any part of the mill without affecting the remainder; or overtime can be worked in any one section at, usually, a less cost than for ordinary working hours. (4) An accurate knowledge of the power taken in each department, and, by means of indicating or recording instruments, a check on the efficiency.

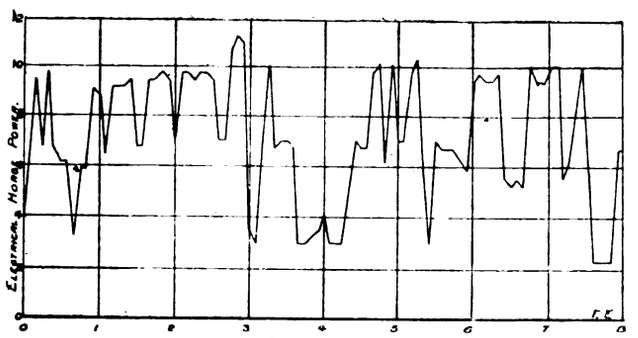

FIG 6.—MILLING SHED LOAD

6. *The Application of Electrical Driving.*—The effect of electrical driving on the general arrangement of a mill is to allow the various machines to be arranged in the natural order of the processes without reference to the position or direction of shafting. In a steam-driven mill the arrangement is decided by the main driving, and in a new mill it is not difficult to lay out a good arrangement; extensions and alterations are, however, nearly always made at the expense of efficiency. The sub-division of the driving accompanying the use of motors may be carried to its full extent, and a motor provided for each machine, doing away thereby with all line shafting. It has found its most successful application in the driving of silk looms, the valuable material worked on making the risk of damage from oil or dirt thrown from a shaft or belt a serious one. The motors, rated at $\frac{1}{3}$ h.p., either drive the looms by gearing or by a single belt, and, to enable the tension of the belt to be adjusted, the motor is swung on an arm and supported by springs; the weight of the motor tends to keep the belt tight, and the tension may be adjusted at will (Fig. 10). Such extreme sub-division is, however, rarely advisable on account of first cost, and group driving must be nearly always adopted. In arranging such driving a considerable saving on the cost of equipment can be effected by increasing the speed of the line shafts, and thereby reducing the size of shafts, pulleys, and hangers—a standard diameter of shaft may often be adopted throughout.

Certain machines have their driving shafts running at a sufficiently high speed to be direct coupled to a motor; doubtless, as electrical driving spreads, textile machine makers will modify their designs so that this will be possible in a larger number of cases. Group driving of from two to four machines without line shafting may be accomplished by fitting the motor with two pulleys. Where a greater number of small machines makes a line shaft a necessity the motor may often be coupled direct to the shaft, being bolted to the wall or ceiling. A reduction of shafting may also be effected by driving the machines on two floors from the one shaft, holes being made in the intervening floor for the belts of the upper machines. Vertical shafts, when necessary, can also be driven by direct-coupled motors—the centrifugal hydro-extractor is an excellent example of the adaptability to this need.

A word of warning may be given as to the installation of motors too large for their work on account of the lessened efficiency and increased cost. Unless the variation of load is extreme, the continuous rating of the motor should correspond with the average load. The small loom induction motors above referred to are designed with a considerable slip and a consequent wide range of efficiency.

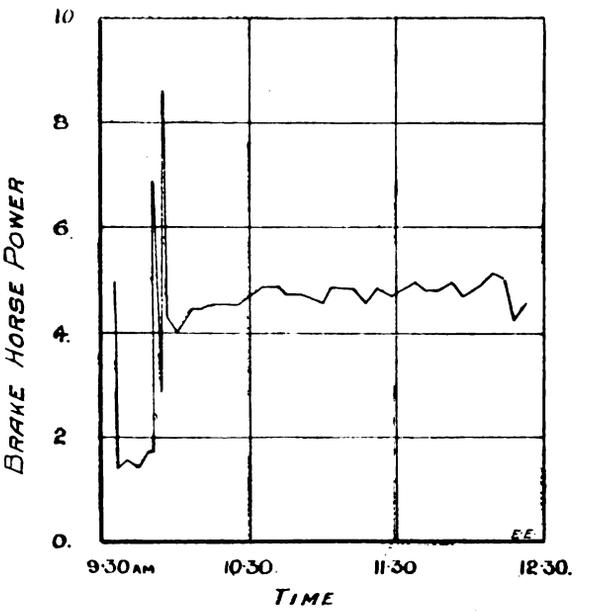

FIG 7 NORMAL RUNNING 65 R.P.M.

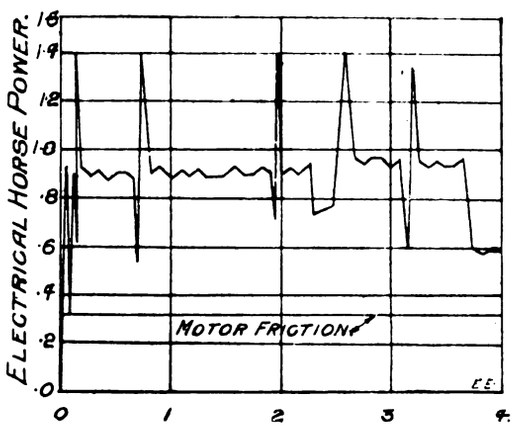
7. *Constancy of Speed as Determining the Nature of the Equipment.*—In the majority of textile operations constant speed is of vital importance; the output of a mill depends on the maximum speed at which the thread can be safely run, and any variation below this results in a decreased output. That regularity of speed at the machines in a "mechanical" mill is never obtained may be realised when one considers that there are often four or five belts between the engine and a machine, the bright surface of the pulleys indicating only too clearly that slipping is never absent. A quotation from a paper by Mr. S. B. Paine, whose experience in electrical driving is unique, bears this out. Referring to a large cotton mill in South Carolina, where the motors were coupled direct to the spinning frames, he says: "The increase in quality and production has been very marked over mechanically-driven frames. I find that there is a very large loss in speed on the frames, due to the slipping of the various belts. In one case the speed on the front rolls in one room varied from 103 r.p.m. to 120 r.p.m. A direct-connected motor showed a range in speed on the front rolls during a week's run of from 120 to 122."

The provision of any speed regulation on motors driving the large majority of textile machines is unnecessary, for the reason that, although different qualities of fibre and different counts of thread require different speeds, yet the manufacturer finds it most economical to keep each machine on a particular class of work. This necessity of constant speed points clearly to the use of polyphase motors in preference to direct-current machines. The advantages of squirrel-cage motors are many; the constancy of speed, the simplicity due to the absence of commutators and sliding contracts, their low cost and the lessened fire risk due to the absence of exposed live metal, are all points in their favour. Their advantages have been

Digitized by Google

recognised by the Fire Offices Committee, and doubtless further concessions will be made as time goes on. With a direct-current equipment more attention is required, and the motor must be completely enclosed. The great objection is, however, the variation of speed at different loads and temperatures. In a case brought before the writer's notice, where shunt motors were used, the complaint was made that on Monday mornings the machinery ran slow, with a consequent reduction of the output of the mill, and the same fault was noticed in a less degree on other mornings; this was, of course, due to the field windings being cold, and to some extent to the extra stiffness of the machinery. The polyphase induction motor under similar conditions would vary in speed by an inappreciable amount.

8. *Variable-Speed Machines.*—The only important class of variable-speed machines is found in textile printing. A detailed consideration of the various equipments which may be adopted are beyond the range of this paper. Multi-voltage direct-current systems, with shunt motors, have much to recommend them in the case of isolated plants, but excellent results have been obtained by the use of a single-supply voltage and motors with double-wound armatures and two commutators. In the latter case a high efficiency is obtained over a wide range of speed. Mention may be made of an equipment adopted in a large printing works in America, where each printing-machine motor was driven from a separate shunt generator, the generators being coupled together and driven at constant speed by a large induction motor. The printing-machine speed was altered by regulating the field of its generator. Such an equipment is, however, too costly for ordinary purposes. The writer's opinion is that almost any known system of speed regulation will meet the case, the determining factors being simplicity and first cost, and the wound rotor induction motor or the direct-current series motor are from this point of view as good as any others.



FIGS:-SINGLE AND DOUBLE HEADBALLING BOXES.

Centrifugal Hydro-Extractors.—The steam-driven centrifugal machine is exceedingly wasteful and messy; the belt or rope driven machine involves a considerable amount of gear in the neighbourhood of the basket, and is very severe on the belts; the direct-coupled electrically-driven machine is compact, simple, and reliable, and can be placed anywhere. Either series direct-current or induction motors motors may be used for this work; the induction motor has an important advantage in that it can never "run away." In practice the motor is completely enclosed and flexibly supported beneath the basket. The time taken to accelerate depends on the maximum torque of the motor at various speeds. Hence, if a squirrel-cage motor is adopted it should be built with a high-resistance rotor, so that the current may be kept down during acceleration. The time taken to accelerate is then practically constant, and the machine needs no attention beyond switching on the motor, which runs up to speed and stays there until switched off. Table A gives the power required for two standard makes of machine

9. *Other Applications of Electricity—Lighting.*—Brief reference may be made to the subject of electric lighting. The matching of colour can only be done satisfactorily by sun or arc light, and in some smoky Yorkshire valleys the sunlight cannot be depended on as a correct source of light. The use of enclosed arc lamps in mills gives excellent results for general illumination; for local lighting the incandescent lamp has the great merit of safety. The greater purity of the air, due to the absence of gas, has an important effect on the health of the workers.

Heating.—Where steady temperatures are required, as in calenders, electrical heating has much to recommend it. Steam joints have a way of giving trouble, and, where higher temperatures are required, gas is found somewhat unreliable. Where current is taken from the public mains the electrical heating of the mill is not out of the question. If the warming up be done at night time, a moderate consumption only is necessary by day.

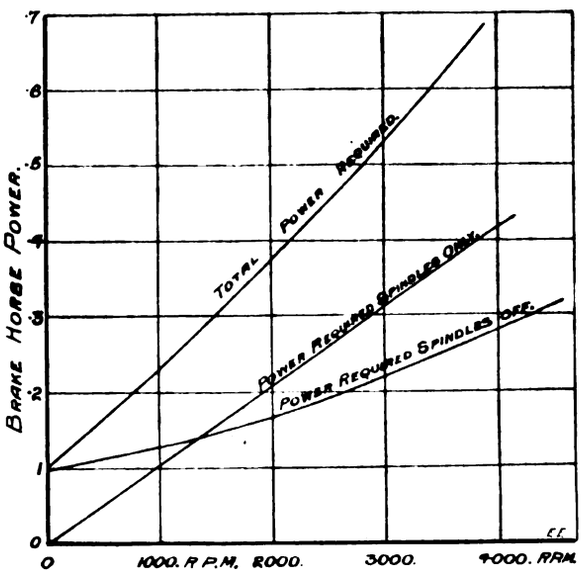

FIG 9:- POWER REQUIRED TO DRIVE RING TWISTING FRAME AT VARIOUS SPEEDS.

Fans.—In addition to the use of electrically-driven fans for ventilating and removing dust, they are finding extended application as a means of transporting wool from the washing machines to the carders, by way of an air-shute connecting the rooms.

NOTES ON AERIAL POWER LINES.—IV.

BY CHE.

(Continued from page 269.)

In designing the supports for aerial power lines the engineer must exercise sound judgment in deciding upon several factors, the values of which can only be obtained by a knowledge of all the local circumstances, and, as in other branches of engineering, experience is the only sure guide. In the remaining paragraphs of these articles the method of applying the mechanical principles already given to the three-phase transmission system (the electrical details of which were deduced in the *Electrical Engineer*, Aug. 18, 1905) will be explained:

Poles are required to carry three copper wires 0·2294in

Digitized by Google

in diameter, and the following particulars respecting copper wires will be found useful in dealing with this problem :

Diameter of wire	0·2294in.
Area of wire	0·04133 square inch.
Weight of copper wire per mile one square inch section	20371·878lb.
Weight of copper wire used per mile	842lb.
Weight of copper wire used per foot length	0·15947lb.
Tensile strength of copper wire per square inch	64,000lb.
Wind pressure per square foot	40lb.
Coefficient of expansion per degree Centigrade	·0000172
Maximum variation of temperature	50deg. C.
Modulus of elasticity of copper wire	16,000,000
Factor of safety for suspended wire	6
„ „ „ the poles	10

It will not be unreasonable to assume 40 poles per mile as the number of poles to employ, so that $\frac{1}{l} = 40$ and $l = 132$ft. = span, and as a first approximation it will be convenient to take one-sixth the breaking strain as the tension to put upon the stretched conductors; consequently

$$F = \frac{\text{weight per mile}}{6} \times c_1 \text{ pounds.}$$

But $$842 \times c_1 = 0{\cdot}04133 \times 64{,}000$$

and $$c_1 = 3{\cdot}142$$

$$\therefore F = \frac{842 \times 3{\cdot}142}{6}$$

$$= 441\text{lb.}$$

The sag is obtained from the formula

$$s = \frac{l^2 w}{8 F},$$

in which w is the resultant of the weight, p_1, of the wire and the wind pressure, p_2, in pounds per foot of wire.

$$\therefore w = \sqrt{p_1^2 + p_2^2}.$$

p_1 is 0·15947lb.

and $$p_2 = \frac{2}{3} \times \frac{12 \times 0{\cdot}2294}{144} \times 40$$

$$= 0{\cdot}51\text{lb.}$$

$$\therefore w = \sqrt{(\cdot 15947)^2 + (\cdot 51)^2}$$

$$= 0{\cdot}534\text{lb.}$$

And by substitution

$$s = \frac{(132)^2 \times 0{\cdot}534}{8 \times 441}$$

$$= 2{\cdot}637\text{ft.}$$

The actual length of wire between the supports is given by

$$L = l + \frac{8}{3}\frac{s^2}{l}$$

$$= 132 + \frac{8}{3} \times \frac{2{\cdot}637}{132}$$

$$= 132{\cdot}0533\text{ft.}$$

So far we have not taken into consideration elastic extension, and to simplify matters let us assume that the wind has ceased, and that hypothetically the weight of the wire has been reduced to an indefinitely small quantity. In such a case the wire will not be stressed, but will contract elastically to a position of zero extension. The contraction is given by the well-known formula

$$l' = \frac{F \times L}{M \times A},$$

in which l' is the change in length, F the applied tension, M the modulus of elasticity of the wire, and A is its area of cross-section in square inches, and

$$l' = \frac{441 \times 132{\cdot}0533}{16{,}000{,}000 \times 0{\cdot}04133}$$

$$= 0{\cdot}088\text{ft.}$$

At the minimum temperature, therefore, the length of wire unstretched will be

$$L_0 = 132{\cdot}0533 - 0{\cdot}088$$

$$= 131{\cdot}9653\text{ft.}$$

Having fixed the maximum variation of temperature as 50deg., C., the length of the wire in consequence of thermal expansion will be

$$L_{50} = 131{\cdot}9653\,(1 + {\cdot}0000172 \times 50)$$

$$= 132{\cdot}0788\text{ft.}$$

The sag corresponding to this unstretched length at the maximum temperature is obtained from the formula

$$L_{50} = l + \frac{8}{3}\frac{s^2}{l}.$$

Thus $$132{\cdot}0788 = 132 + \frac{8}{3} \times \frac{s_1^2}{132}$$

and $$s_1 = 1{\cdot}9745\text{ft.}$$

It must next be assumed hypothetically that the wire has its normal weight restored, in which case the sag will be increased until the tendency to elongate, due to gravity stress, is just balanced by the elastic tendency to contract, but as the connection between the resultant sag and the factors, which take into account the temperature and elastic effects, is a cubic equation, a graphical solution will be given instead of the analytical one.

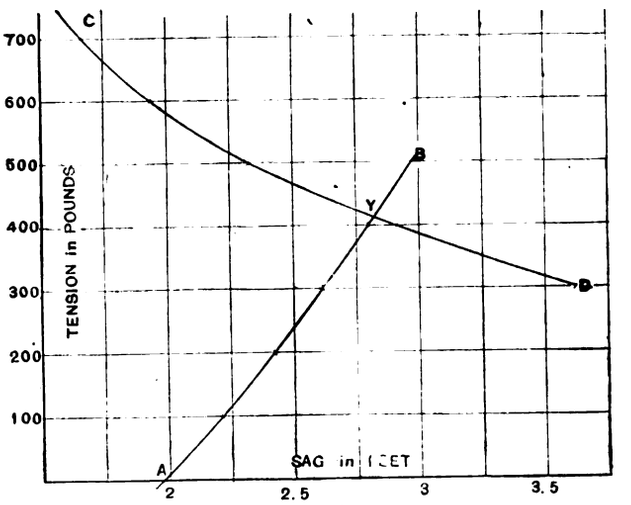

FIG. 10.

In the first place, we require a curve representing the relation between the tension and corresponding sag in the wire, as the wire sags under gravity stress from its hppothetical position of zero tension, and this is plotted from the results calculated on the assumption that the tension is increased from zero by applying the formulæ

$$l' = \frac{F \times L}{M \times A} \text{ and } L = l + \frac{8}{3}\frac{s^2}{l}.$$

Commencing with the sag at maximum temperature and zero tension—*i.e.*, 1·9745ft.—assume certain increasing tensions in the wire, and from the increased length given by the former equation obtain the corresponding sag by means of the latter, which when plotted give the curve A B in Fig. 10. Thus—

When F is lb.	l is ft.	L is ft.	s is ft.
0	0	132·0788	1·9745
100	0·01997	132·0988	2·211
200	0·03995	132·1188	2·42
300	0·0599	132·1387	2·62
400	0·0799	132·1587	2·80
500	0·0999	132·1787	2·97

Another curve is also required showing the relation between the tension and the sag in the wire at various tensions, when the wire is assumed to have its normal weight per foot, and this curve—*i.e.*, C D in Fig. 10—is found by taking different values of F in the equation $s = \frac{l^2 w}{8 F}$, when w is the weight of the wire per foot. Thus—

Digitized by Google

When F is lb.	s is ft.
700	1·661
600	1·937
500	2·325
400	2 907
300	3·876

In this case the two curves A B and C D intersect at the point Y, giving the sag as 2·82ft. at the maximum temperature, and as this is the point of equilibrium at which the force of elastic contraction is balanced by the gravity stress, it gives the condition in which the wire is strung, so that at minimum temperature it will be stressed at one-sixth its breaking strength, corresponding to its factor of safety of 6.

As regards the dimensions of the poles for supporting the wires, the following notes afford an example of applying the principles already given. The conditions of the problem are: Three wires of diameter 0·2294in. have to be supported at the corners of an equilateral triangle of 62in. side, the apex being at the top. The maximum sag is 2·82ft. Distance between poles 132ft.

Assuming the free height of the lower wires to be 40ft. as the minimum, the height of the pole above the ground must be 40 + 2·82 + 4·5, or 47·32ft., since the top insulator is approximately 4·5ft. above the bottom ones. Allowing 5ft. as the depth of setting the poles in the ground, the actual length of the pole must be 52·32ft., and as poles of pine may be obtained in suitable lengths, we may assume, as an example, that the poles are of pine. The tendency to bend the poles is due to the wind pressure upon the wires and the pole. If T_1 is the resistance to rupture at the bottom of the poles, then, as we have already shown,

$$\frac{\pi d_2^3 T_1}{32} = F' h',$$

where $F' h'$ is the summation of the bending moments due to the wind, and this equation enables us to determine d_2, the diameter of the pole at the bottom close to the ground. Now, since the wind pressure upon each wire is 0·51lb. per foot length, the stress due to the wind pressure on each line wire will be $p_2' = 132 \times 0{\cdot}51 = 67{\cdot}32$lb.; therefore,

Bending moment of the top wire

$$= M_1 = F_1 h_1 = 67{\cdot}32 \times 47{\cdot}32 = 3{,}186 \text{ pound-feet.}$$

Bending moment of each lower wire

$$= M_2 = F_2 h_2 = 67{\cdot}32 \times 42{\cdot}82 = 2{,}882 \text{ pound-feet.}$$

Bending moment of wind upon the pole

$$= -\left[\frac{2}{3} \times 40 \times h \times \frac{d_1 + d_2}{12 \times 2}\right] \times \frac{h}{2}$$

$$= \frac{2}{3} \times 40 \times h \times \frac{5}{72} d_2 \times \frac{h}{2}$$

$$= \frac{80}{3} \times \frac{(47{\cdot}32)^2}{2} \times \frac{5}{72} d_2$$

$$= 2{,}074\ d_2.$$

Note $d_1 = \frac{2}{3} d_2$.

Now, $F' h' = F_1 h_1 + 2 F_2 h_2 + 2{,}074\ d_2$

$$= 3{,}186 + 5{,}764 + 2{,}074\ d_2.$$

$$\therefore\ 0{\cdot}0982\ d_2^3\ T_1 = 8{,}950 + 2{,}074\ d_2.$$

With a factor of safety of 10, $T_1 = \frac{1}{10}$ of 5,000 = 500lb

$$\therefore\ 0{\cdot}0982\ d_2^3 \times 500 = 8{,}950 + 2{,}074\ d_2,$$

and

$$d_2^3 - 42{\cdot}24\ d_2 - 182{\cdot}25 = 0.$$

To solve this equation, let $y = d_2^3$ and $y_1 = (42{\cdot}24\ d_2 + 182{\cdot}25)$, then

$$y - y_1 = 0,$$

which is a convenient form for solving the equation graphically, by assuming several values of d_2 and calculating the corresponding values of y and y_1, which when plotted will give two curves which intersect, and the point of intersection will give the value of d_2 required. Thus

When x is	0	2	4	6	7	8	9
y	0	8	64	216	343	512	729
y_1	182·25	266·73	351·21	435·7	478	520	562

The equation $y = d_2^3$ is represented by Curve I. in Fig. 11, and the equation $y_1 = (42{\cdot}24\ d_2 + 182\ 25)$ by Curve II. The point of intersection, Y, gives the value of d_2 as 8·1in. This means that if the pole has a diameter of 8·1in. at the bottom close to the ground, the pole offers a factor of safety of 10 against a wind pressure of 40lb. to the square inch. In practice, however, it is unusual to employ poles for power transmission work with a diameter less than 8in. at the top, and since $d_2 = \frac{3}{2} d_1$, this gives the diameter at the bottom as 12in, consequently with the thicker pole

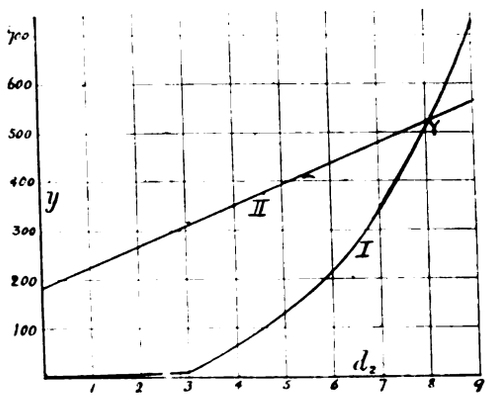

FIG. 11.

the factor of safety would be greater than 10. It may be remarked that the high voltage and the comparatively small amount of power dealt with in this example accounts for the somewhat small poles required.

HORN LIGHTNING ARRESTERS.

In his paper read before the Electric Club of Pittsburg, Mr. N. J. Neall gave a *résumé* of the present American practice in lightning arresters for high-voltage transmission circuits. The information is of special value to those engineers putting up power transmission lines overhead in this country. We propose to confine our extracts from the paper to the type of arrester known as the "horn," which was invented in Germany by Oelschlaeger, and developed by the Allgemeine Elektricitäts-Gesellschaft. The feature of the arrester is that the short-circuit arc once started by lightning at the narrow gap between the horns (Fig. 1), is caused by the heat of the arc to travel upwards along the horns and break by reason of its attenuation. Of course, a certain amount of time is required to do this. The author states that this time may be something like two seconds, and that on large plants the resulting short-circuits would not only be objectionable, but in many cases where synchronous apparatus could fall out of step it would be prohibitive. At the International Electrical Congress at St. Louis, Mr. F. G. Baum, of the San Francisco Gas and Electric Corporation, stated that on their system (formerly the Bay Counties and Standard Electric Companies, now working in parallel) this type of arrester had been known to operate frequently without affecting the service, and no effect was felt at distant points. At another plant of the company a horn arrester has been known to operate without blowing the fuse in series with it. In the following will be found a description of typical and important high-tension installations using these arresters.

The arrester used by the Standard Electric Company is illustrated in Fig. 2. The three legs of the main line pass from the transformer and high-tension switch-room, A, directly through the building, B, emerging at *c c c*, and thence to the transmission line, D D D. The horn arrester, or the "Dutchman," as it is generally called, is connected to the line at *c c c*. As the picture shows, the apparatus is very simple—in fact, its cheapness is strongly in its favour. As used at Electra it consists of an air-gap at F in series with a water resistance, and an iron wire resistance and a choke coil, H, from which it is connected to the ground. The knee-shaped spark terminals are formed of about No. 0000 copper wire, supported on the regular line insulator; the water resistance consists of copper strips immersed in a salt solution contained in the jars, G, which

Digitized by Google

are of about 15 gallons capacity each. The salt water is covered with about ⅛in. of oil to prevent evaporation. The resistance choke coils consist of about 18 turns of iron wire wound on a 6in. cylinder, the cylinder being removed before mounting. The arrangement is shown diagrammatically in Fig. 3. The gap, F, is adjustable. While operating at 40,000 volts the distance was 3in. to 3¼in. The protector as described was installed by Mr. A. C. Bunker in 1902, while he was in charge, and the same device is now in use

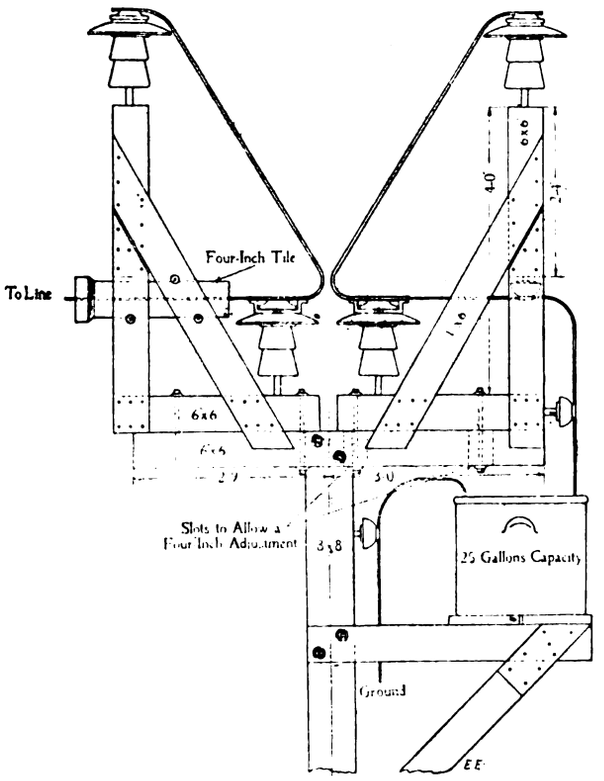

FIG. 1.—Horn Lightning Arresters as constructed by the American River Electric Co.

on the lines of the California Gas and Electric Corporation, which now owns and operates the Standard plant. Mr. Bunker lays great stress on the curve of the knees, and the form shown in Fig. 3 was adopted after considerable experimenting. If the wires separate too abruptly above the gap, the arc will not follow up and extinguish itself; if the crook in the knee is too sharp, the arc will either hold on

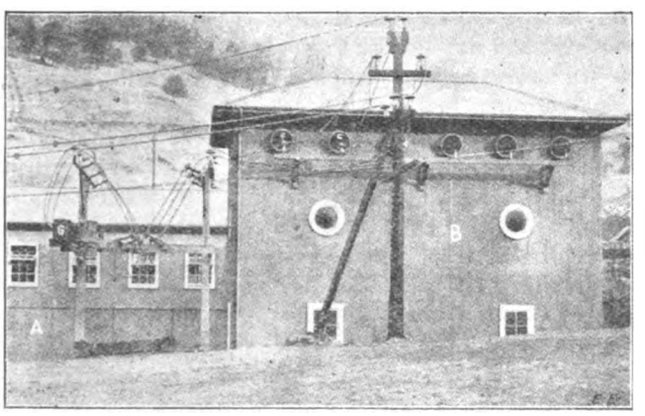

FIG. 2.—Horn Arrester outside Transformer Station of the Standard Electric Co.

or rise and extinguish itself and immediately strike back again at F. Further, the curve of the knee depended on the value of the line constants at the point protected, for a curve that gave the best satisfaction at one point on the line was not the best at another.

In California, the lightning storms lack the severity and frequency of those further east, but as an instance of the value of the protection afforded against line surges, Mr. N. A. Eckert mentions some switching experiments carried on at Mission San Jose, 100 miles from Electra. These experiments or tests were for the purpose of establishing the value of a certain type of switch, and consisted of closing and opening the switch with 10,000 kw. at 40,000 volts behind it. As a rise in the line voltage was expected, the gap, F, at the power-house was increased to 4¼in. About the fourth time the switch was opened the arrester discharged and the arc extinguished itself. The test was repeated and the arrester again discharged, but so violently as to blow all the water out of the resistance jars. No damage was sustained by any of the transformers or instru-

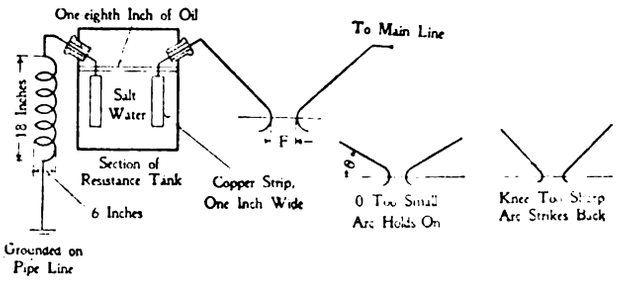

FIG. 3.—Details of Connections and as to Best Shape of Horns.

ments. He does not know of any transformer being broken down by lightning or similar disturbances where protected by this apparatus. The chief objection offered to it is the length of time the arc or short holds on after the discharge to ground. This may be as long as a second or a second and a half. However, the arrester does not discharge very frequently.

The American River Electric Company use the arrester, as shown in Fig. 1. The horns are of galvanised iron gas-pipe, and for the voltage of about 40,000 they are separated about 2¼in. A jar of water, covered with oil, is used for a resistance in the ground wire. The oil, of course, is simply to reduce the evaporation. The company have used both pure water and water with salt added, but find the pure water more satisfactory. These arresters have been in operation for about 18 months, and have gone through several lightning storms. Several of the employés have witnessed their action during the storms. In one instance they discharged several times in succession, the arc travelling about half-way up the horn before breaking. Every discharge had the same effect as a temporary short-circuit, causing the voltmeters to swing entirely across the scale, and the lights to dip to perhaps ½ c.p. Mr. B. C. Condit writes that they have had no trouble from these arresters, no damage done by lightning, and consider the arrester as satisfactory for high voltages as any now in use.

APPOINTMENTS VACANT.

Draughtsman for works in North of England. Apply to Box O 8, *Electrical Engineer* office. See advertisement in last issue.

Canvasser, wages 25s. per week and commission. Letters only, Midland Electric Corporation for Power Distribution, Limited, 73, Lichfield-street, Wolverhampton. See advertisement in last issue.

Engineers in charge of a H.T. generating station. Salary from £27 to £29.—Apply to X 55, *Electrical Engineer* office. See advertisement in last issue.

District Representative for firm of manufacturing electrical engineers. Apply to "Electric," care of Hart's Advertising Offices, 6, Arundel-street, Strand, W.C. See advertisement in last issue.

Junior Engineer, Erith Urban District Council electricity works. Applications by Sept. 18. See advertisement.

PERSONAL.

The marriage of Mr. O. L. Falconar, A.M.I.E.E., senior partner of the firm Falconar, Cross, and Co., 4, St. Nicholas-buildings, Newcastle-on-Tyne, and Miss Elizabeth Bell took place at North Shields on the 2nd inst.

The Johannesburg Council has confirmed the appointment of Mr. J. F. I. Thomas as general manager of the lighting and tramways undertaking. Mr. Thomas has been the resident engineer for Messrs. Mordey and Dawbarn, the consulting engineers to the Council.

FORTHCOMING EVENTS.

SATURDAY, SEPT. 9.

Birmingham Electric Club.—At 7.30 p.m., social evening.

THE OXFORD TRAMWAYS.

The expiration of the authorised life of the horse tramways of the city of Oxford gives the Corporation a chance to purchase the system on the well-known tramway terms. This is to be done, and the question then arose as to what should be the future policy of the Council as to the transport facilities within its area. The two courses open were either to re-equip the tramways for electric traction, which will necessitate new permanent way, or to replace the same by a service of motor 'buses. Before deciding on the first course, as has been done this week, two reports were obtained from the leading exponents of the rival systems. Mr. Stephen Sellon was selected to advise as to the results which could be obtained by electric tramways, and Mr. W. Worby Beaumont's opinion as to motor omnibuses was taken. As it is the first time that a large town has thoroughly gone into the matter, we reproduce these two reports in full so that our readers may have before them the complete evidence as to the rival systems. In the table following these reports are the figures as to the service proposed in each case, the cost of equipment, and the estimates as to the results to be attained. To these figures we shall presently refer, but at once it must be remembered that Oxford is not on a par with most towns in the United Kingdom. As Mr. Beaumont says, "It is a city with a character all its own; a city which has not yet lost its charm and its distinctiveness through accretions and adaptations of things incongruous. In considering for it, then, a system of public passenger conveyances, it must be remembered that a system which would be permissible in a striving manufacturing town would not necessarily be expedient or desirable in Oxford." This consideration, coupled with the narrowness of several of the streets to be traversed, is greatly in favour of the motor 'buses, which are not confined to one definite part of the street. Mr. Beaumont also presented some attractive figures as to the probable receipts and expenditure. In the latter item he included 20 per cent. for depreciation, which is equivalent to allowing only a five years' life to the motorcars. It will be noted, however, that the carrying capacity of the seventeen motor vehicles is thirty-four as against the seating accommodation of forty-eight in the electric cars and forty in the existing horse cars. Thus a comparison between the working expenses per mile run, which are 8·7d. for the motorcar and sixpence for the electric car, is too favourable to the former vehicle. Adjusted for the carrying capacity, the figure for the motorcar to transport forty-eight passengers would be in the neighbourhood of a shilling, or double the cost with electric traction. This is a very large difference, and it no doubt led to the decision above mentioned. The chief reason for the increased cost is an essential one, which cannot be removed by experience in design. A metal wheel running on a well-laid steel rail reduces the tractive effort required to a point which cannot be approached by any type of tyre traversing the ordinary surface of a road. The nearest approach to tramway conditions as far as smooth running is concerned is obtained with rubber tyres, and at the expense of the same. Figures as high as twopence to twopence-halfpenny per mile run are common for the upkeep of rubber tyres on motor 'buses. Such a cost is practically double the six per cent charge required at Oxford to cover the interest and sinking fund instalment on the capital to be spent on the new permanent way and the electrical equipment of the routes. With internal-combustion engines placed in tramcars, and driving the same, the charges for tyre repairs and for increased tractive effort would be eliminated, but there is still enough margin between the figures of cost to warrant electric transmission of the power required on the car from

Digitized by Google

an economical central station. A careful perusal of the two reports leaves the impression that motor vehicles have not yet reached a stage at which they can be considered as strong rivals of electric tramways. There are, however, other uses to which they can be put which may make them valuable adjuncts to electric lines. Thus the marked difference between the two systems lies in the low first cost of the motorcar as compared with a tramway system needing permanent way. On routes, therefore, with a very infrequent service—say three or four cars a day each way—it may be found that the extra cost of running motor 'buses is less than the capital charges for permanent way. In such cases the motor 'bus will serve to develop a district which may ultimately need a light railway or tramway to connect it to the nearest town. Returning to Oxford, we note that the incongruity of overhead wires in its principal and historic streets is to be avoided by a surface-contact system of electric traction.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

RE LINE CALCULATION.

SIR,—The writer wishes to thank "Newcastle" for his lucid remarks *re* the $C^2 R$ loss and its relation to the load factor in last week's correspondence column. I find that "Alternator" in his answer to the question under discussion makes the same mistake as did the writer; for his solution is based on "the lost energy being proportional to the load factor," which "Newcastle" points out is not correct.

Re "Newcastle's" formula for lost volts, the writer sees nothing wrong with it, yet at the same time it does not seem to me to agree with Ohm's law. Can "Newcastle" say what is wrong with the following formulæ, which the author uses, but which give a different result to "Newcastle's"?

Taking a 40-mile line, three wires No. 8 S.W.G., with 50,000 volts between any two wires:

(*a*) By Ohm's law $E = C R$, where E = lost volts in any two wires, C = current = 14·5 amperes, R = resistance of 40 miles lead and return = 80 miles 8 S.W.G. = 171·32 ohms. ∴ volts lost = 2,484.

(*b*) My formula is evolved as follows from Ohm's law, where E = volts lost in *one* wire, C = current = 14·5 amperes, R = resistance of one line = 40 miles of 8 S.W.G. = 85·66 ohms.

$$E = C R$$
$$= C R \times \frac{3C}{3C} = \frac{3C^2 R}{3C}.$$

∴ lost volts in *two* wires lead and return

$$= \frac{3C^2 R}{3C} \times \frac{2}{1} = \frac{3C^2 R}{1{\cdot}5\,C} = \frac{\text{total energy loss}}{1{\cdot}5 \times C} = 2{,}484 \text{ volts}$$

By "Newcastle's" formula $C R \sqrt{3}$ lost volts = 14·5 × 85·66 × $\sqrt{3}$ = 2,152 volts.—Yours, etc.,

DUPLICATOR

["Duplicator's" formula does not take into account the difference of phase between the currents and E.M.F.'s in the three line wires. Thus, with a loss of 1,242 volts in each line wire, the algebraic sum of the losses in two wires is not 2,484 volts, but 1,242 + (1,242 × cos 60) = 2,152 volts.—ED. *E. E.*]

REVIEWS.

Modern Lightning Conductors. By KILLINGWORTH HEDGES, M.I.C.E. Crosby Lockwood and Sons, London. 6s.

The author of this volume is the hon. secretary of the Lightning Research Committee, whose report was recently issued and commented upon in our columns. This report was the result of four years' work, and had of necessity to give only an abstract of the information collected. In the book before us much additional information is published as to the details of the damage done by lightning to various buildings throughout the country. This is accompanied by sketches and photographs which make the path of the lightning clear in most cases. Such detailed information is most valuable. Elsewhere in the book will be found the suggestions and rules of the Research Committee, which were drawn up after a consideration of the reports on a large number of lightning strokes. These are commented on by the author, who gives also some specifications which will guide surveyors and architects in the right direction. To the electrical engineer, the reports as to standard practice in foreign countries will be most interesting, and the experience obtained from some districts where storms are very prevalent is most valuable. The chapter dealing with this part of the subject includes reports from Germany, Holland, and Hungary, and notes on special systems used in Belgium, France, and Italy. The Melsen system used in Belgium seems to be a step towards the network system of protection advised by the English committee. It is used on the Hotel de Ville at Brussels, and the only damage recorded was proved to be due to the neglect to connect an horizontal bar of metal to the network of copper conductors. The information given in the volume is most valuable, but we are somewhat surprised to see some of the daily paper cuttings reproduced in chapter ix. This deals with "Fulgurites and Other Vagaries of Lightning," but some of the matter is more concerned with the vagaries of the newspaper reporters. In records of lightning accidents it is not easy to get a scientific statement of what occurs, and on such occasions the local reporter is apt to draw on his natural store of legends. It is for this very reason that the reports of the observers of the Lightning Research Committee are so valuable. The volume is one which will be appreciated both by the electrical engineer and by those who, having no electrical knowledge, have to protect buildings from lightning.

ELECTRIC TRAMWAYS v. MOTOR OMNIBUSES.

Oxford Reports.

The Corporation of Oxford have this week decided to purchase the existing horse tramways and to reorganise the system for electric traction. The decision has been arrived at after a careful consideration of the two following reports from Mr. Stephen Sellon and Mr. W. Worby Beaumont respectively. Additional information was also supplied by these engineers, amongst which was a tabulated comparison of the results expected from the rival system. This table we also reproduce. Mr. Sellon's report, dated Aug. 5, 1905, to the town clerk reads:

To the Town Clerk, Oxford.

Sir,—In response to the request contained in your letter of July 14, and availing myself of the further information received at the meeting of your committee and my subsequent visit, I now have the honour to present for your Council's consideration the conclusions to which I have come.

To deal with the instructions in the letter quoted in the order stated, first, "the form of traction most suitable for Oxford, taking into account the interests of passengers, ratepayers, all classes of road users, and residents on the routes involved." Considering, in the first place, the routes covered by the existing tramways, I have no hesitation in stating that the interests of all concerned will be best met by a tramway service constructed and worked on modern lines. The fact that the existing tramways with the present service carry so large a traffic as that shown by the annual reports of the company proves conclusively that no other than a tramway method can give such good results.

The general argument in favour of tramways as against other systems of traction is that the additional capital expenditure results in a large economy in working expenses, from which it follows that, if the traffic is sufficiently great, the total of capital charges and of working expenses will be lower on a tramway than if carried by other methods of road traction. That this is the case in regard to the routes I am now considering is quite clear, because the passengers

Digitized by Google

carried and the traffic receipts shown with horse traction are quite sufficient to justify the capital expenditure on an electric tramway of the best modern construction. This opinion is the result of my experience of 20 years over some 60 different undertakings, some new and some converted, representing about 600 miles in all, and an expenditure of £6,000,000. Assuming for the moment that the receipts would remain at the same figure, the economy in working would more than off-set the capital charges involved. Therefore, I have no hesitation in recommending the Council that electric tramways will best meet the requirements.

The assumption that the receipts from the traffic will remain the same, is one not justified by experience. The reasonable presumption is that these figures will increase considerably, and to provide the necessary accommodation for such increase it will, in my opinion, be prudent to construct a greater length of double line than that which is found on the existing tramway routes. This is particularly the case as regards the main routes crossing at Carfax, where the lines in both directions should be doubled. On the north and south route this should be from the corner of Beaumont-street and St Giles to the south end of the town hall buildings in St. Aldate's-street, and on the east and west route from the western end of Queen-street to the corner of Turl-street and High-street.

In view of the construction in parts of these streets, I propose to so construct the double lines there that whilst the cars are kept on their proper side of the road they will not be able to pass each other, thus leaving ample room for the other traffic on either side. In my view the doubling of the lines near Carfax is eminently desirable, not only for the purposes of the tramway traffic, but for the better regulation of the other road traffic, the observance by the tramcars of the rule of the road in such places being decidedly beneficial.

I have carefully considered the instructions of the committee, "that the Council will not entertain any scheme involving the erection of posts and wires between the east end of Magdalen Bridge and the west end of Queen-street, nor between the north end of St. Giles's-street and Folly Bridge, and will regard with special favour any scheme which dispenses entirely with posts and wires within the city." The effect of this decision is that within the limits prescribed either a conduit system or one of the surface-contact systems can alone be considered. I have gone closely into this matter, and it appears to me that on the ground of expense a surface-contact system is the only one which can be adopted. Now the track mileage within the area from which posts and wires are barred is 2·434, and the electrical equipment of this position on the surface-contact system will cost about £3,000 per track mile, or £7,300 within the area mentioned. This figure is one which the scheme can bear, whilst the cost of a conduit would, in my opinion, make the annual capital charges assume an excessive proportion of the gross receipts.

I have to point out that both the surface-contact and the conduit systems involve an additional expense outside their own cost, because there is interference with pipes and other works in the street. The amount of this is quite impossible to estimate without a detailed knowledge of the subterranean works along the routes, and I have not allowed any particular amount for such work. The conduit system requiring excavation and construction to a depth of nearly 3ft., and the surface-contact systems to a depth not exceeding 2ft. from the street surface, it will be obvious that the conduit is the more expensive in this respect. The city engineer, who is thoroughly acquainted with the local conditions, can give your committee a much closer estimate of the amount and cost of such work than I can venture to offer. It is claimed that the working expenses on a surface-contact system are not greatly, if at all, in excess of those with an overhead equipment.

The question of safety is, of course, of the greatest importance. The surface contact presents a greater potential danger than either the overhead or the conduit, because the live conductors from which the car derives its supply of power are, in the former case, on a level of the street surface. All the systems which have been brought forward provide, as a matter of course, that these live conductors or studs shall be alive only while a car is passing over and taking current from them, and that the onward passage of the car shall automatically disconnect and leave them dead. It will be obvious that the failure of this automatic disconnection will leave on the street surface a charged conductor, capable of giving extremely severe shocks to any foot passengers or animal which may tread upon it. The great endeavour of all inventors in this field has, therefore, been to render the automatic action absolutely reliable.

With one exception, the motive power of all the practicable surface-contact systems now on the market is derived from magnets carried below the car body. These magnets act upon movable iron pieces in the box under the stud and actuate switches connecting the stud surface to the supply cable. As soon as the car with its magnet moves on, the moving parts under the stud resume their normal position and the stud is disconnected. The exception has a mechanically-actuated switch worked by strikers carried on the car. One of the running rails is slotted, the strikers project downwards into the slot and there meet the actuating mechanism of the switch. A front striker turns current on to the stud, and a rear striker turns it off. The only remark I would make about this method is that it seems to involve the disadvantages of a conduit slot in the street and a more expensive track construction. In this country there is only one town, as the committee are probably aware, in which a surface-contact system has been in practical use—viz, Wolverhampton. There were some initial troubles during the first months of operation in that town, some cases of animals being killed and injured, but the greater part of the trouble was due to the interruption of service in consequence of failures of this kind. It is claimed that these troubles have now disappeared and that the surface-contact system in Wolverhampton works with as much reliability and with no more danger to the public than the overhead trolley system. Clearly, in selecting a system for adoption in Oxford the committee and their advisors will have to look very closely into the reliability of the various devices offered in this respect, and the Council will be well advised not to decide to adopt any particular system excepting after consideration of tenders, accompanied with a satisfactory guarantee providing for the continuous reliable action and maintenance expenses, and, what is more important, the continuous approval of the Board of Trade. Full details for the consideration of the Council's technical advisers will, of course, be necessary.

Outside the limits mentioned I recommend the adoption of the overhead system. From the point of view of commercial success, of economical maintenance, and of general reliability and safety, no other method can compete with the overhead system. It has had the advantage of the experience of many years under very varying conditions, and has shown itself capable of serving the very heaviest traffic with the greatest reliability, and the smallest traffic on which a tramway can pay with great economy. This is of the greatest importance, as enabling the maximum profitable extensions to outlying districts.

The cost of the overhead electrical equipment need not exceed £1,300 per route mile. This expenditure does not compare accurately with the cost per track mile for the surface-contact or the conduit system, for the reason that the overhead work costs no more for a double line than for a single line, whereas either the conduit or the surface-contact system costs practically twice as much for double line as for single, so that contrasting a mile of double line the surface-contact work would cost £6,000 and the overhead work £1,300, whilst with single line in both cases the surface-contact work would cost £3,000 and the overhead work £1,300 as before, so that in considering the relative cost the amount of single and double line has to be taken into account.

As regards instruction No. 2, I recommend the Council, when it has been duly considered and decided what lines it is advisable to construct with such estimates as it may see fit to obtain, to call for tenders for the construction and equipment of these tramways upon proper specifications. These specifications should, as in ordinary course, be so divided up as to enable the Council to place the contracts for the various parts of the work in the most

Digitized by Google

advantageous manner. As above stated, particular attention will have to be given to any portions of the lines which will be constructed with the surface-contact equipment to ensure that the specification calls for substantial guarantees and safeguards in respect to this comparatively untried form of construction.

It appears to me that the best course to meet instruction No. 3 is to lay before your Council my views as to the expenditure and the probable gross and net receipts to be derived from tramways constructed in a modern way. The first point to be considered is the gauge, and here I am clearly of opinion that the standard gauge of 4ft. 8½in. is the most suitable. Other gauges have been adopted in some towns for a variety of reasons; none of these operate in Oxford, while the advantages of the standard gauge as regards more comfortable rolling-stock, more convenient disposition of the electrical equipment, and the possibilities of future intercommunication, all seem to me to have full force, and to call for the adoption of the gauge 4ft. 8½in.

Single and Double Line.—In the centre of the town, on either side of the crossing of the main routes at Carfax, the lines should be doubled, as above stated. There should also be an extension of double line in St. Aldate's-street north of Folly Bridge. Elsewhere a sufficient number of loops to provide for a five minutes' service appear to me to meet the requirements, and the remainder of the line should be single track. In the estimate of construction costs which follows I have taken into account this proposed proportion of single and double line, which gives me the route mileage at 5·375 and the track mileage at 7·291 miles. The track mileage on which posts and lines cannot be entertained amounts to 2·434 miles, and that on which posts and wires are permissible to 4·857 miles, the route mileage being 3·87.

Generating Station.—There are suitable sites for a generating station to be found either in Twenty Pound Meadow, or adjacent property, well situated for economical power generation and distribution.

Car-Shed.—The site now used for the tramway company's depôt is very suitable for housing the proposed rolling-stock, and my estimate covers its adaptation for the purpose.

I estimate that the capital expenditure in constructing and electrically equipping this suggested system will be as follows:

Permanent way—7·291 miles single track	£40,106
Overhead work—3 87 route miles	5,031
Surface-contact work—2 434 track miles	7,302
Feeder cables—5·375 route miles	5,375
Rolling-stock—20 cars	14,000
Generating station, including machinery, with a capacity of 400 kw.	10,000
Car-shed building and equipments	3,000
	84,814
Promotion, engineering, and contingencies	8,481
Total	£93,295

Traffic Estimate.—The traffic returns of the tramway company show that during the year 1903 the tramcars carried 2,716,500 passengers, and that the total receipts were £13,190. Experience has taught me that a very safe basis is that an electric tramway service will carry traffic of 40 per cent. greater value than a horse tramway on the same ground and the same population. There are many cases in which the increase has been much larger. I am not aware of any where it has been less, and from what I have seen of Oxford, I feel sure that 40 per cent. is quite a moderate increase to allot. On this basis the receipts of the electrified tramways will amount to £18,360 per annum, which, it will be observed, works out at a rate of £3,416 per route mile. The working expenses should not exceed 60 per cent. of the receipts, so that the revenue account will stand thus:

Gross receipts	£18 360
Working expenses, 60 per cent.	11,016
Net revenue	£7,344

From this net revenue has to be met the interest and sinking fund upon the capital expenditure. Assuming this to be as high as 61 per cent., it will be seen that there is a substantial credit balance to be anticipated. I am therefore confident that the tramways suggested will be financially successful, as well as a great improvement and convenience to the inhabitants and visitors of Oxford.

I have given separate consideration to the extension from the present tramway termini to the suburban and outlying districts, and I am of opinion that it would be financially advantageous to the tramway system as a whole, and necessarily a great benefit to the population of the city and outlying districts, to make the following extensions, which the committee will find indicated upon the enclosed map.

Extensions, etc.	Length, miles.	Cost of construction and equipment, including share of rolling-stock.
Headington	1·75	£14,000
Iffley	1·3375	10,700
Cowley	·6125	4,900
Hinksey	·4375	3,500
Walton-street and Kingston-road line	·275	2,200
Banbury-road	·194	1,552
	4·6065	£36,852

Considering very carefully the amount and distribution of the population on these extensions, I have come to the conclusion that the amount of traffic receipts to be anticipated in consequence of their construction, including the mutual feeding effects between this and the central system, will be fairly proportional to the length of individual extensions, and that the gross receipts thereon will have a value of not less than

(annually)	£9,213
Deducting therefrom working expenses of	5,528
Leaves a balance of net receipts of	3,685
Interest and sinking fund on the capital expenditure of £36,852 amounts to	2,211
	£1,474

So that a balance of between £1,400 and £1,500 will remain after satisfying these charges.

Summarising the whole financial results, I put forward the following figures:

Capital expenditure—central system	£93,295
Ditto branches	36,852
Total	£130,147
Gross receipts—central	£18 360
Ditto branches	9,123
Total	27 573
Working expenses	16,544
Net receipts	11,029
Interest and sinking fund	7,809
Net balance	£3,220

I strongly recommend your committee and Council to give their fullest consideration to a complete scheme, and it is for this reason that I have outlined the whole of the extensions described. I would point out that in any application for powers to carry out these works the Council can ask for such a period for construction as will leave the order and date of execution within the discretion of the Council. In my opinion, looking at the character of the districts to be served, the extension along the Iffley-road will be the most immediately remunerative of those mentioned, whilst those to Cowley and Headington seem to promise the greatest ultimate development.

I have for the convenience of the committee put into the form of appendices a statement showing what I think will be the value to the whole system of each extension, including its feeding effects. It will be noted that in the above estimates no allowance is made in any way for the acquisition of the existing tramways.

I trust that the above information will enable your Council to decide upon the next steps to be taken, and I shall be pleased to supplement this report with any details on which the Council would like further explanation.—I am, sir, yours faithfully, STEPHEN SELLON.

Mr. W. Worby Beaumont's report is dated Aug. 9, and read as follows:

Outer Temple, 222, Strand, London, W.C.

Richard Bacon, Esq., Town Clerk, Oxford.

Dear Sir,—In the following I beg leave to submit to the Corporation of Oxford my report in accordance with the instructions received from you and the further instructions

Digitized by Google

received at the time of my visit on the 22nd ult. from the Tramways Committee. On that occasion I made a general inspection of the whole of the routes now traversed by tramways, those of proposed extensions, and those of the present omnibuses. I have previously visited and stayed in Oxford on several occasions, and have thus made myself acquainted with the city, and the streets and roads of the city and suburbs, and the traffic to be provided for.

In your letter of the 14th ult. you inform me that "the committee have decided that the Council will not entertain any scheme which involves the erection of posts and wires between the east end of Magdalen Bridge and the west end of Queen-street, nor between the north end of St. Giles and Folly Bridge." The same letter instructs me "(1) to advise the Council as to the form of traction most suitable for Oxford, taking into account the interest of passengers, ratepayers, all classes of road users, and residents on the routes involved." I have been provided by Mr. White, M.I.C.E, with particulars as to the lengths of the several Oxford city tramways at present existing, and of those which have been proposed, and I have received from you particulars of the tramway and omnibus traffic of the past 4½ years in the six directions and districts served. I have fully considered the existing accommodation with regard to Oxford, and the "form of traction most suitable in the future, taking into account the interest of passengers, ratepayers, all classes of road users, and residents on the routes involved." All the roads and streets of Oxford and the connected districts are, from a transport point of view, practically level, or have but slight gradients. Comparatively small maximum power per vehicle will be thus required, the power needed for acceleration or quick getting away being the chief determining demand.

The Oxford city tramways comprise a total length of 6⅞ miles single horse-car line, including a total length of 1⅜ miles of turn-out loops. In 1904 they carried 2,841,315 passengers. The greatest length of line is that of the Cowley-road to the station, which is a little over 2½ miles of single line in all, and this carried in 1904 1,614,302 passengers, or 51·65 per cent. of the whole of those carried by the tramways, and is about 645,000 passengers per mile of single line. The next tramway in length is the Banbury-road line, 2¼ miles in length total of single line with the extensions, and this carried 734,094 passengers in 1904, or 30·7 per cent. of the whole, and about 322,000 passengers per mile. The Hinksey line is the next in length, 1$\frac{1}{17}$ miles, carried only 190,594 passengers, or only 6·7 per cent. of the whole, and 180,000 per mile. The Walton-street lines, under one mile of single line in length, carried 302,335 passengers, or only 10·5 per cent. of the whole, or 350,000 per mile of line. The Iffley-road omnibuses carried 335,310 passengers in the year. The Woodstock-road omnibuses carried 95,305 passengers in the year.

The variation in the number of passengers carried during the past six years has been almost negligible by both tramways and omnibuses; the total by trams, for instance, in 1899 being 2,730,274, as against 2,841,315 in 1904, or a growth of less than 1 per cent. per year. In the same time the passengers by omnibuses have grown in numbers from 341,900 in 1899 to 430,615 in 1904, or a growth of 21 per cent. in the years following 1899, or over 4 per cent. per year. Examination of these figures and of the populations of the several wards shows that the passengers carried by the tramcars and by the omnibuses differed enormously, as would be expected. The number of journeys per head of the respective populations being, as near as it is possible to allocate them, as follows: East Ward, Central, and University, 70 journeys per head; St. Giles, 70; St. Thomas, 35; and St. Aldate, 49. This, of course, does not necessarily show that the inhabitants of St. Thomas and St. Aldate travel so much, as appears, less than those of the other wards, but that the tram and omnibus traffic on the roads of those wards is and will be the greatest. These figures, as a total, give less than the total of 62 journeys per year made by the whole population of 52,836 on the whole of the lines, showing that the populations overlap in relation to the services, as they would, for instance, in the use of the St. Thomas's service. These figures give some idea of the quantity and distribution of the traffic at present and of the probable distribution in future with somewhat increased facilities.

At present 13 tramcars are in use and three omnibuses. The tramcars have thus carried about 218,000 passengers per car per year. The omnibuses have carried per 'bus 143,538 passengers. Taking the population of the central and five surrounding districts as 52,800, the total journeys by tram and 'bus represent 62 journeys per head per year, which is equal to or exceeds that of more than one-third of the towns and cities in the United Kingdom in which the tramways are electrically operated (about one-sixth of which, as shown by the returns of 1903-4, are worked at a loss). This large number of apparent journeys per head per year—large considering the facilities—must be taken in considerable degree as due to large numbers of visitors.

The disproportion in the number of journeys made per head of the population of the several Oxford districts would, there can be little doubt, be modified to some extent if a quicker, and by a quicker a more frequent, service were established. There is not, however, in my opinion any necessity for a system of very large carrying capacity in Oxford city and districts. At an outside estimate it is possible that about 100 journeys per head of population per year might be made if a sufficient system were established.

I assume that it is wished to provide ample accommodation, that this accommodation should at least be self-supporting, and that it is not thought desirable or expedient in such a city as Oxford to make a tramway trade. I also assume that the amenities of Oxford should be considered as precedent of any question of assumed profit, or trading returns, which may be possible from any system of cheap popular public conveyance.

Although Oxford has increased and is increasing in population, its general character and distinction as a great university city have remained without changes which would have affected its dignity and unique attractiveness. It has remained true to its attributes and ancient and lofty associations, yet has encouraged that progress which does not militate against the preservation of the spirit of its ideals—ideals which have made it in the eyes of the world the city of history, learning, and repose. It is a city with a character all its own; a city which has not yet lost its charm and its distinctiveness through accretions and adaptations of things incongruous. In considering for it, then, a system of public passenger conveyance, it must be remembered that a system which would be permissible in a striving manufacturing town would not necessarily be expedient or desirable in Oxford.

With regard, then, to a system of traction most suitable for Oxford, and the paragraph before quoted in the instructions given me. At the time of expiry of the present ownership of the existing horse tramways the tramways will in great part be useless for any other than horse traction. They might be extended now in several directions, but no material improvement in the service could be made where the possible traffic most requires it firstly, because almost the whole of the lines are single way; secondly, because in several parts the streets are not wide enough to permit the construction and use of double lines; thirdly, because their use if constructed would cause great inconvenience to every other kind of traffic, and in many cases cause congestion. Most of these objections refer equally to any system of tramway traction.

The existing tramways, then, will have no more than the value of their material when the time comes for making a change. I am of opinion that, when that change is made and the existing permanent way removed, no more rails should be put down. I do not even think that the traffic of any part of the city or the connected districts would be benefited by the establishment of any system of electric tramway, but distinct advantages would result from the reconversion, now that the opportunity will arise, of all streets and roads at present laid with rails, into well-made and well-maintained ordinary paved, macadam, wood, or other of the best clear surface roadways suitable for every kind of vehicle.

Oxford, as before remarked, is mainly a level-road city, and the traffic density is not and will not be great. It will be well suited for, and well suited by, a public service

of motor omnibuses; the working of which does not interfere with any other traffic, requires no special roadway not equally required by every other class of vehicle, is the system best suited for narrow streets, requires no special installation or new establishments, and with a moderate maximum speed will give a higher average speed than can be obtained by any system of tramway. The motor omnibus system requires no overhead wires or posts and cross-wires to carry them, and requires not only no rails in the streets, but no conduits or no surface contacts. The reasons which have decided your committee to refuse to entertain any scheme which involves the erection of posts and wires along certain routes should equally obtain with respect to other routes, as these things are not now necessary to the desired end in any places where the traffic density is not extremely heavy, and they certainly should hold good in the narrower and the narrow streets not included in the routes excluded. The motor omnibus would be suited for the traffic of all the streets and roads in which tramways are not at present laid, and they would provide, without the laying of any lines, for the service of any street or roads not now served, such as Woodstock-road, without any expenditure except for the omnibuses themselves. The motor omnibus requiring no special roadway can at any time be put to work on any route to suit special circumstances or changed conditions. A new route may be tried and served, or one not requiring or paying for a service may be abandoned temporarily or permanently without any loss at any time.

I am, therefore, of opinion that: (1) "The form of traction most suited for Oxford" is the motor omnibus. (2) "The interest of passengers" would be best met by the motor omnibus, as (*a*) with equal maximum speed being quicker than any other system; (*b*) as being more flexible and lending itself without extra cost to change of route on special occasions, to the opening up of new routes, and to the minimum of delay in narrow streets; (*c*) convenience of access or of alighting at the pavement instead of the middle of the street. (3) That "the interest of the ratepayers" is best met by the motor omnibus, as (*a*) involving much less capital outlay at first or for extensions; (*b*) because they could be worked at a profit; (*c*) because with comparatively small expenditure the present tramway depôts can be converted into motor-'bus depôts and workshops; (*d*) because their road requirements are those of every user, and well made and maintained roads are the most economical. (4) "The interest of all classes of road users" is best met by the motor omnibus because they do not interfere with other users (*a*) by appropriating a definite part of the highway; (*b*) because they can accommodate themselves to any circumstances of the traffic; (*c*) because they do not require any rails in the roadway; (*d*) because for their use they only require the ordinary road, and their use encourages the making and maintenance of good roads and surfaces, which are more economical in the end than cheaply-made and inefficiently maintained roads. (5) "The interests and convenience of the residents on the routes served" are best met by motor omnibuses, because (*a*) they do not involve road obstruction for tramway lines construction; (*b*) they do not require the ringing of bells to clear every other kind of traffic off their fixed routes; (*c*) they do not interfere with the carriages stopping at shops or private houses at the road or street side; and (*d*) because they enable the passenger to enter or alight from them at the pathway.

Experience has now shown that motor omnibuses can be run profitably; great improvements have been made in them in the past two years, and the very wide experience now being obtained will lead rapidly to further improvements, and they will, there can be no doubt, in every way meet the requirements of the service, every month now adding to their development and their durability.

For use in Oxford, which is now served by 13 tramcars and three omnibuses, I would recommend the installation of 16 or 18 motor omnibuses, 10 or 12 of them to carry 34 passengers and six to carry 16 passengers, their selection as to make and maker to be decided hereafter, but to be of the internal-combustion motor type. These could be put to work as obtained and without waiting for the removal of the tramways. Addition to this number of omnibuses could be made if and as required. The total cost of the number first to be put in service would be about £14,000, and the expenditure on the depôt and workshops about £6,000, or a total of £20,000. Powers for this expenditure and for running this service would have to be obtained.

In coming to the conclusion herein set forth, I wish to say that I am not averse to the use of tramways where they are most suited, and as a member of the council of the Tramways and Light Railways Association I would encourage their use in wide roads where traffic is very heavy, and along roadsides in some cases; but I am convinced that for Oxford the electric tramway, either of the overhead, the conduit, or any surface-contact system, is not the best, is not required, and that the motor omnibus does meet the requirements.—I am, faithfully yours,

W. Worby Beaumont.

At the request of the Council these two engineers each supplied the figures in the table herewith given in the columns under their names. With these figures before them the Corporation of Oxford passed a resolution in favour of electric tramways, which, we believe, will include the extensions mentioned in Mr. Sellon's report as well as the conversion of the existing lines.

DIAMONDS.

The following is a condensation of a lecture on "Diamonds" delivered by Sir William Crookes, F.R.S., before a meeting of the British Association at Kimberley this week. The lecture was most appropriate to the place of delivery, and seats to hear it were at a premium.

Sir William Crookes said it was recorded in "Sprat's History of the Royal Society" (1667) that among the questions sent by order of the society to Sir Philiberto Vernatti, resident in Batavia, was one inquiring "Whether diamonds grow again after three or four years in the same places where they have been digged out?" The answer sent back was "Never, or at least as the memory of man can attain to." South Africa was the favourite haunt of diamonds on this planet; it ranked with Australia and California as one of the three great gold-yielding regions

Digitized by Google

But the wealth of South Africa was not limited to gold and diamonds. It was also the illimitable home of coal—"the black diamond" of the universe. The province of Natal alone contained more coal than Britain ever owned before a single bucket had been raised; and the coal beds extended into the Orange River Colony. Valuable iron ores existed also in large quantities. In addition to these lavish natural riches the high grounds above Cape Town abounded in medicinal health-giving waters. He had studied diamonds scientifically for 30 years. In 1896 he spent nearly a month at Kimberley, when Mr. Gardner Williams, general manager of the De Beers Consolidated Mines, and the managers of neighbouring mines, did their utmost to aid him with valuable information. The most famous diamond mines were Kimberley, De Beers, Dutoitspan, Bultfontein, and Wesselton. Kimberley was practically in the centre of the present diamond-producing area. The mines were situated in latitude 28° 43′ south and longitude 24° 46′ east. There were also river washings in the neighbourhood of the Vaal River, where the work was conducted in somewhat primitive fashion. When he was at Klipdam miners had congregated at a spot called "New Rush," where some good finds of diamonds had been reported. At one of the claims the proprietor said he had not seen a diamond for a fortnight! But then he had picked out one worth £300, "and that," he said, "will pay for several weeks' wages of my boys." This was the kind of speculative gambling that went on at the river diggings.

The surface of the country round Kimberley was covered with a ferruginous red, adhesive, sandy soil, which made traffic heavy. Below the red soil was a basalt, much decomposed, and highly ferruginous, from 20ft. to 90ft. thick, and lower still from 200ft. to 250ft. of black slaty shale containing carbon and iron pyrites. There was no water nearer than the Vaal River, about 14 miles away; formerly the miners were dependent on rain-water and a few springs and pools. Now, however, a constant and abundant supply of excellent water was served to the town. Good brick houses, with gardens and orchards, had sprung up on all sides. The five diamond mines were all contained in a precious circle 3½ miles in diameter. They were irregular shaped round or oval pipes, extending vertically downwards to unknown depths, retaining about the same diameter throughout. They were considered to be volcanic necks, filled from below with a heterogeneous mixture of fragments of surrounding rock, and of older rocks such as granite, mingled and cemented with a bluish-coloured hard clayey mass, in which famous blue clay the embedded diamonds were hidden. The areas of the mines were: Kimberley, 33 acres; De Beers, 22 acres; Dutoitspan, 45 acres; Bultfontein, 36 acres. How the great pipes were originally formed was hard to say. They were certainly not burst through in the ordinary manner of volcanic eruption, since the surrounding and enclosing walls showed no signs of igneous action, and were not shattered or broken up even when touching the "blue ground." It was pretty certain these pipes were filled from below after they were pierced, and the diamonds were formed at some previous time and mixed with a mud volcano, together with all kinds of *débris* eroded from the rocks through which it erupted, forming a geological "plum pudding" There were many such pipes in the immediate neighbourhood of Kimberley. It might be that each volcanic pipe was the vent for its own special laboratory—a laboratory buried at vastly greater depths than we had yet reached—where the temperature was comparable with that of the electric furnace, where the pressure was fiercer than in our puny laboratories, and the melting point higher, where no oxygen was present, and where masses of liquid carbon had taken centuries, perhaps thousands of years, to cool to the solidifying point. This hypothesis of the origin of diamonds was in many ways corroborated. The ash left after burning a diamond invariably contained iron as its chief constituent; and the most common colours of diamonds, when not perfectly pellucid, showed various shades of brown and yellow, from the palest "off colour" to almost black. They were also green, blue, pink, yellow, and orange. These variations gave support to the theory advanced by Moissan that the diamond had separated from molten iron, and also explained how it happened that stones from different mines, and even from different parts of the same mine, differed from each other. Further confirmation was given by the fact that the country round Kimberley was remarkable for its ferruginous character, and iron-saturated soil was popularly regarded as one of the indications of the near presence of diamonds. Along with carbon, molten iron dissolved other bodies which possessed tinctorial powers. One batch of iron might contain an impurity colouring the stones blue, another lot would tend towards the formation of pink stones, another green, and so on. Cobalt, nickel, chromium, and manganese, all metals present in the blue ground, would produce these colours.

The blue ground varied in its yield of diamonds in different mines. According to tables furnished by the De Beers Company, the yield of the De Beers and Kimberley mines had declined as the depth increased. At the same time the value of the stones had risen, and diamonds were more expensive to-day than at any previous time. The number of carats per load (about 1,600lb.), a carat being 3⅕th troy grains, or rather less, had fallen from 1·283 in 1889 to ·54 in 1904; but in the same period the value per carat had risen from 19s. 8·75d. to 48s. 11·8d. The diamonds from each mine had a distinctive character, and so uniform were the characteristics that an experienced buyer could tell at once the locality of any particular parcel of stones. De Beers and Kimberley mines were distinguished by the yield of large yellowish crystals with curved edges; Dutoitspan yielded mainly coloured stones; while Bultfontein, half a mile off, produced small white octahedral crystals, occasionally speckled and flawed, but rarely coloured. The diamonds from the Wesselton mine were characterised by the large number of perfect octahedra of pure water amongst them. The diamonds from the Leicester mine had a frosted, etched appearance; they were white, the crystallisation irregular ("cross-grained"), and they were hard and expensive to cut. Stones from Jagersfontein, in the Orange River Colony, displayed great purity of colour and brilliancy, and they had the so-called "steely" lustre characteristic of old Indian gems.

Sir William Crookes then gave a description of the diamond mines 30 years, and compared the method of working individual claims then with the present system now that the work is carried out under one management. Speculations as to the probable origin of the diamond had been greatly forwarded by patient research, and particularly by improved means of obtaining high temperatures, an advance we owed principally to the researches of Prof. Moissan. Until recent years carbon was considered absolutely non-volatile and infusible; but the enormous temperatures at the disposal of experimentalists—by the introduction of electricity—showed that, instead of breaking rules, carbon obeyed the same laws that governed other bodies. It volatilised at the ordinary pressure at a temperature of about 3,600deg. C, and passed from the solid to the gaseous state without liquefying. It had been found that other bodies, such as arsenic, which volatilised without liquefying at the ordinary pressure would easily liquefy if pressure were added to temperature.

It naturally followed that if, along with the requisite temperature, sufficient pressure were applied, liquefaction of carbon would take place, when on cooling it would crystallise. But carbon at high temperatures was a most energetic chemical agent, and if it could get hold of oxygen from the atmosphere or any compound containing it, it would oxidise and fly off in the form of carbonic acid. Heat and pressure, therefore, were of no avail unless the carbon could be kept inert. For the manufacture of an infinitesimal diamond, the first necessity was to select pure iron—free from sulphur, silicon, phosphorus, etc.—and to pack it in a carbon crucible with pure charcoal from sugar. The lecturer then described the process, which was, he said, in parts extremely tedious. In the result along with numerous pieces of black diamond were seen transparent colourless pieces, some amorphous, others with a crystalline appearance. All appear shattered, as if, on being liberated from the intense pressure under which they were formed, they burst asunder. A fine piece of artificial diamond, carefully

Digitized by Google

mounted by him on a microscopic slide, exploded during the night and covered the slide with fragments. Moissan's crystals of artificial diamond sometimes broke a few weeks after their preparation, and some of the diamonds which cracked weeks or even months after their preparation showed fissures covered with minute cubes. This bursting paroxysm was not unknown at the Kimberley mines. The largest artificial diamond was less than 1mm. across. In lustre, crystalline form, optical properties, density, and hardness, they were identical with the natural stone. In several cases Moissan separated 10 to 15 microscopic diamonds from a single ingot. The larger of these were about 0·75mm. long, the octahedra being 0·2mm.

Intermediate between soft carbon and diamond came the graphites. The name graphite was given to a variety of carbon, generally crystalline, which in an oxidising mixture of chlorate of potassium and nitric acid formed graphitic oxide. This varied in colour from green to brown or yellow, or it was almost without colour, according to the completeness of the reaction. Graphites were of varying densities, from 2·0 to 3·0, and generally of crystalline aspect. Graphite and diamond passed insensibly into one another. Hard graphite and soft diamond were near the same specific gravity. The difference appeared to be one of pressure at the time of formation. Some forms of graphite exhibit the remarkable property by which it was possible to ascertain approximately the temperature at which they were formed, or to which they had subsequently been exposed. Sprouting graphite was a form frequently met with in nature which on moderate heating swelled up to a bulky, very light mass of amorphous carbon. Moissan had found it in blue ground from Kimberley; his own results verified his. The resistance of a graphite to oxidising agents was greater the higher the temperature to which it had previously been exposed. Graphites which were easily attacked by a mixture of fuming nitric acid and potassium chlorate were rendered more resistant by strong heat in the electric furnace. After dealing with the boiling and melting point of carbon and a new formation of diamond, Sir W. Crookes said that, sensational as was the story of the diamond industry in South Africa, quite another aspect fixed the attention of the chemist. The diamonds came out of the mines, but how did they get in? How were they formed? What was their origin? Gardner Williams, who knew more about diamonds than any man living, was little inclined to indulge in speculation. In his fascinating book ("The Diamond Mines of South Africa," p. 510: Macmillans. 1902) he frankly said: "I have been frequently asked, 'What is your theory of the original crystallisation of the diamond?' And the answer has always been, 'I have none; for after 17 years of thoughtful study, coupled with practical research, I find that it is easier to "drive a coach and four" through most theories that have been propounded than to suggest one which would be based on any non-assailable data.' All that can be said is that in some unknown manner carbon, which existed deep down in the internal regions of the earth, was changed from its black and uninviting appearance to the most beautiful gem which ever saw the light of day."

Another diamond theory appealed to the fancy. It was said the diamond was a gift from Heaven, conveyed to earth in meteoric showers The suggestion was first broached by A. Meydenbauer (*Chemical News*, vol. lxi., p. 209. 1890), who said: "The diamond can only be of cosmic origin, having fallen as a meteorite at later periods of the earth's formation. The available localities of the diamond contain the residues of not very compact meteoric masses which may, perhaps, have fallen in prehistoric ages, and which have penetrated more or less deeply, according to the more or less resistant character of the surface where they fell. Their remains are crumbling away on exposure to the air and sun, and the rain has long ago washed away all prominent masses. The enclosed diamonds have remained scattered in the river-beds, while the fine light matrix has been swept away." According to this hypothesis, the so-called volcanic pipes were simply holes bored in the solid earth by the impact of monstrous meteors — the larger masses boring the holes, while the smaller masses, disintegrating in their fall, distributed diamonds broadcast. Bizarre as such a theory appeared, he was bound to say there were many circumstances which showed that the notion of the heavens raining diamonds was not impossible. The most striking confirmation of the meteoric theory came from Arizona. Here, on a broad open plain, over an area of about five miles in diameter, had been scattered one or two thousand masses of metallic iron, the fragments varying in weight from half a ton to a fraction of an ounce. There was little doubt these masses formed part of a meteoric shower, although no record existed as to when the fall took place. Curiously enough, near the centre, where most of the meteorites had been found, was a crater with raised edges three-quarters of a mile in diameter and about 600ft. deep, bearing exactly the appearance which would be produced had a mighty mass of iron struck the ground and buried itself deep under the surface. Altogether 10 tons of this iron have been collected, and specimens of the Canyon Diablo meteorite were in most collectors' cabinets. An ardent mineralogist—the late Dr. Foote—cutting a section of this meteorite, found the tools were injured by something vastly harder than metallic iron. He examined the specimen chemically, and soon after announced to the scientific world that the Canyon Diablo meteorite contained black and transparent diamonds. This startling discovery was afterwards verified by Profs. Moissan and Friedel, and Moissan, working on 183 kg. of the Canyon Diablo meteorite, had recently found smooth black diamonds and transparent diamonds in the form of octahedra with rounded edges, together with green hexagonal crystals of carbon silicide. The presence of carbon silicide in the meteorite showed that it must, at some time, have experienced the temperature of the electric furnace. Since this revelation, the search for diamonds in meteorites had occupied the attention of chemists all over the world. He was enabled to show his hearers photographs of true diamonds he himself had extracted from the Canyon Diablo meteorite.

Diamonds varied considerably in hardness, and even different parts of the same crystal differed in their resistance to cutting and grinding. Beautifully white diamonds had been found at Inverel, New South Wales, and from the rich yield of the mine and the white colour of the stones great things were expected. In the first parcel which came to England the stones were found to be so much harder than South African diamonds that it was at first feared they would be useless except for rock-boring purposes. The difficulty of cutting them disappeared with improved appliances, and they now were highly prized. The famous Koh-i-noor, when cut into its present form, showed a notable variation in hardness. In cutting one of the facets near a yellow flaw, the crystal became harder and harder the further it was cut, and after working the mill for six hours at the usual speed of 2,400 revolutions a minute little impression was made. The speed was increased to more than 3,000, when the work slowly proceeded. Other portions of the stone were found to be comparatively soft, and hardened as the outside was cut away. Although not directly bearing on the subject, he would introduce the only serious rival of the diamond as regards hardness. It was the metal tantalum, a fine specimen of which he owed to Messrs. Siemens Bros. A hole had to be bored through a plate of this metal, and a diamond drill was used revolving at the rate of 5,000 revolutions per minute. This whirling force was continued ceaselessly for three days and nights, when it was found that only a small depression ¼mm. deep had been drilled, and it was a moot point which had suffered most damage—the diamond or the tantalum. In another respect tantalum was likely to rival graphitic carbon, as it had rivalled adamantine carbon. Its thin wire was extensively used for filaments of incandescent electric lamps; it showed a much higher efficiency than did the old carbon filament. The melting point of tantalum was about 2,300deg. C., a temperature seldom or never reached in an ordinary lamp.

After exposure for some time to the sun many diamonds glowed in a dark room. Some diamonds were fluorescent, appearing milky in sunlight. In a vacuum, exposed to a high-tension current of electricity, diamonds phosphoresced of different colours, most South African diamonds shining with a bluish light. Diamonds from other localities emitted

Digitized by Google

bright blue, apricot, pale blue, red, yellowish green, orange, and pale green light. The most phosphorescent diamonds were those which were fluorescent in the sun. One beautiful green diamond in his collection, when phosphorescing in a good vacuum, gave almost as much light as a candle, and you could easily read by its rays. But the time had hardly come when diamonds could be used as domestic illuminants! Diamonds which phosphoresced red generally showed the yellow sodium line superposing on a continuous spectrum. In one Brazilian diamond phosphorescing a reddish-yellow colour, he detected the citron line characteristic of yttrium. By permission of Mrs. Kunz, wife of the well-known New York mineralogist, he would show, perhaps, the most remarkable of all phosphorescing diamonds. This prodigy diamond would phosphoresce in the dark for some minutes after being exposed to a small pocket electric light, and if rubbed on a piece of cloth a long streak of phosphorescence appeared. The rays which made the diamond phosphoresce were high in the ultra-violet. A thin sheet of glass cut them all off.

The β-rays from radium having like properties to the stream of negative electrons in a radiant matter tube, it was of interest to ascertain if they would exert a like difference on diamonds. The diamond glowed under the influence of the β-radiations, and crushed diamond cemented to a piece of card or metal made an excellent screen in a spinthariscope — almost as good as zinc sulphide. Some fine colourless crystals of diamond were embedded in radium bromide, and kept undisturbed for more than 12 months. At the end of that time they were examined. The radium had caused them to assume a beautiful blue colour, and their value as "fancy stones" had been materially increased. Sir W. Crookes showed his audience a couple of diamonds originally of the same purity of water. One had been coloured by radium, the other was in its natural state. The colour of the radium-tinted stone was very pronounced. This blue colour was persistent, and penetrated below the surface. It was unaffected by long continued heating in strong nitric acid and potassium chlorate, and was not discharged by heating to redness. To find out if this prolonged contact with radium had communicated to the diamond any radioactive properties, six diamonds were put on a photographic plate and kept in the dark for a few hours. He would project the image of the result after development. The three on the upper row were the diamonds which had had a prolonged sojourn with radium, the three below were similar diamonds picked out for comparison, which had not been near radium. It would be seen how strangely the upper ones had acted. They would notice also that by mere contiguity to the others the lower diamonds also shone with an induced factitious radioactivity. He would throw on the screen a magnified image of one of the blue crystals, and they would see in how regular and geometrical a pattern the radioactive emanations radiated from the crystal. This observation had only been made a short time, and was still under investigation. Like the blue tint, the radio activity persisted after drastic treatment. A diamond that had been coloured blue by radium, and had acquired strong radioactive properties, was slowly heated to dull redness in a dark room. Just before visibility a faint phosphorescence spread over the stone. On cooling and examining the diamond it was found that neither the colour nor the radioactivity had suffered appreciably. The diamond was remarkable in another respect. It was extremely transparent to the Röntgen rays, whereas highly refracting glass, used in imitation diamonds, was almost perfectly opaque to the rays. He exposed for a few seconds over a photographic plate to the X-rays the large Delhi diamond, of a rose-pink colour, weighing 31½ carats, a black diamond weighing 23 carats, and a glass imitation of the pink diamond. On development, the impression where the diamond obscured the rays was found to be strong, showing that most rays passed though, while the glass was practically opaque. By this means imitation diamonds could readily be distinguished from true gems.

We are indebted to the *Times* for the text from which the above condensation has been prepared.

TRADE NOTICES AND NOVELTIES

Lundberg Specialities.

The accompanying diagrams (Figs. 1 and 2) illustrate two useful adaptations of the "Pivot" combined tumbler switch and wall connection manufactured by A. P. Lundberg, Pioneer Electrical Works, London, N. Several other adaptations are shown in a pamphlet just issued by Mr. Lundberg. As for the

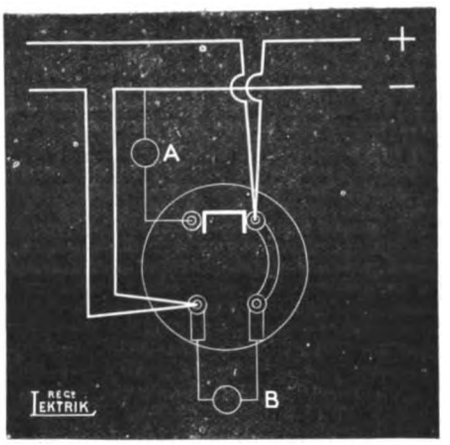

FIG. 1.—Switch and Plug controlling independent circuits.

combination itself, this has been already described in our columns. Suffice it here to say that the variable spring leverage action produces a very definite and easy movement, with both on and off positions, effectively locking the contact arm in the former. Four substantial terminals are provided, and the connecting strap may be readily removed. By the use of such

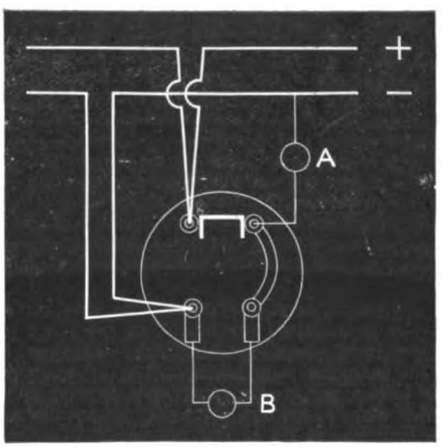

FIG. 2.—Switch controlling both plug and switch circuits.

combination fittings considerable economy may be effected both in material and labour, quite apart from the convenience obtained. The "Pivot Intermediate" switch is another useful type, of which we have particulars from the same source. This switch is especially suitable for corridor and staircase lighting, also for drawing, dining, and bed room lights,

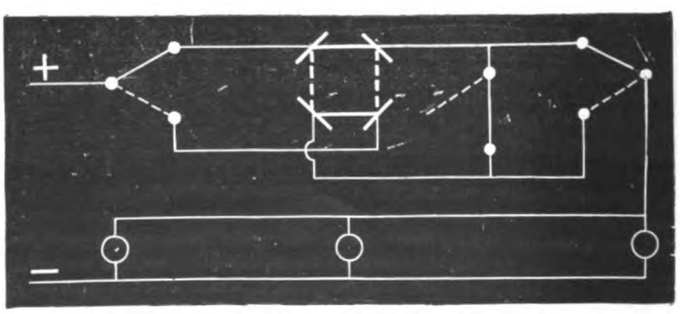

FIG. 3.—Master Switch in combination with "Pivot Intermediate" Switches.

enabling such to be controlled from any number of positions desired. The diagram (Fig. 3) illustrates one method of wiring it up in combination with "Pivot" two-way switches. It will be noticed that all the switches are arranged on one pole only, consequently safe working is ensured. The master switch may be introduced as shown anywhere in the circuit, so that,

Digitized by Google

when turned on during legitimate hours of lighting, no movement of any of the other switches will extinguish the lamps and cause annoyance to the users. Take a typical case as used in flats. Up to 11 p.m. it is desired that the corridor and staircase lights shall be illuminated continuously, and that no movement of any of the other switches shall extinguish them. After that hour the switch knob is thrown over on to one of the other contacts to extinguish the lamps. These may be again illuminated or extinguished by any of the other switches in circuit, during the night, as desired. Following are suggestions for the application of the "Pivot Intermediate" switch: (1) a long corridor may have a number of doors opening into it, and it is desirable to control the lamps illuminating it from either end or intermediate door; (2) in a house of several floors it is undoubtedly an advantage to be able to turn off the staircase lights from either ground, top, or intermediate floor or landing; (3) a large room with, say, three or four doors may have the lamps illuminating it similarly controlled from any door or other desirable position.

Small Rotary Converter Set.

We understand that the Rhodes Electrical Manufacturing Company, Limited, Bradford, are standardising a small rotary converter set suitable for charging motorcar accumulators. It consists of a double-wound machine suitable for 110 or 230 volts at one end and 4 to 25 volts at the other, this latter voltage being regulated by the rocking of the brushes only. Where electric power is available the set is used as a rotary converter to convert to low voltage for cell charging, and in this case requires no foundation whatever, but will stow away in a corner or under a bench, or will hang from the ceiling. Where electric power is not installed, the machine is belted to the line shaft, and when driven in this manner will supply the necessary high-tension current for the pit inspection lamps, and also the low voltage necessary for accumulator charging. Where electric power is installed, it can be used to drive any small machine tool using not more than ½ h.p. at the same time as it is being used for charging purposes. Twelve cells can be charged at once, and the set is found to be very useful in automobile garages. There should be an increasing demand for this machine; it seems to us to be just the thing that is wanted.

Catalogues, etc, Received.

E.P.S. Batteries.—From the Electrical Power Storage Company, Limited, 4, Great Winchester-street, E.C., we have a copy of a neat little pamphlet which they have just brought out giving illustrations and particulars of a few central-station batteries they have supplied. Some of these batteries are of very large capacity, and the numerous repeat orders obtained by the firm tell a satisfactory tale of their reliability in working. It is worthy of note that the Liverpool Corporation have no less than 13 E P.S. batteries installed. At the General Post Office, London, a battery of 700 K type E.P.S. cells has been installed for telegraphic purposes. These cells replace 30,000 primary batteries. Similar type batteries are also in use, we gather, in the post offices at Liverpool, Manchester, Leeds, Birmingham, Glasgow, Newcastle, Cardiff, etc. The manufacturers would, therefore, seem to supply a large proportion of the orders given out by the Post Office Department for batteries, due no doubt to the proved excellence of their speciality. The firm's special motorcar and electric launch cells are dealt with in another publication.

Measuring Instruments.—The latest *brochure* from Messrs. Ferranti Limited, Hollinwood, Lancs., deals with the firm's switchboard measuring instruments in a very entertaining manner. It is excellently printed, and contains numerous illustrations of an instructive character. The reader of this paragraph is recommended to apply for a copy.

TUNBRIDGE WELLS ELECTRICITY ACCOUNTS.

The accounts of the Tunbridge Wells electricity department for the year ended March 31, 1905, show a total expenditure on capital account to that date of £80,949. Abstracts of the revenue account, balance-sheet, etc., are appended.

Revenue Account.

Dr. Expenditure.	£	s.	d.

LEGAL INTELLIGENCE.

OBSTRUCTION OF CARS.

At the Wigan Police Court last week Robert Morris was charged with obstructing a Corporation car, by refusing to move his lorry. The case for the prosecution was that as the car approached the loop the driver rang the bell so that the lorry might clear the loop before the car overtook it, the road being somewhat narrow at this point. In consequence of the lorry continuing to move slowly the two vehicles came into contact.

Corroborative evidence was given by a passenger.

The defendant stated that he did not hear the bell, and that there was time for the car to pull up.

After arguments by counsel, the Bench decided that there was not sufficient evidence to convict.

At the Bradford City Police Court, R. Bracewell, the driver of a laundry van, was fined 5s. and 11s. costs for obstructing an electric car on the Manningham route.

The evidence of the car driver showed that although he rang the gong repeatedly defendant refused to leave the track, and the car was delayed seven minutes.

Defendant denied having heard the gong, and said he was riding inside the van.

In answer to the stipendiary magistrate, defendant said that when riding inside the van he could not hear people shouting in the street.

The stipendiary magistrate pointed out that if he could not hear when inside the van he could not be aware of any danger, and it was very dangerous for a driver to be boxed up in a van, unable to hear or see what was going on.

LONG-FIRM PROSECUTION.

The charge against George Webber and Richard T. Rozenberg, reported in our last week's issue, was proceeded with at the Guildhall on Monday, when the case was again adjourned.

TRAMWAY AND TELEPHONE WIRES.

In the Court of Session Lord Ardwell had before him in the Bill Chamber a note of suspension and interdict at the instance of the National Telephone Co., having their chief office at Telephone House, Victoria-embankment, London, and a district office at Royal Exchange-buildings, Glasgow, against the Falkirk and District Tramways Co., having its principal office at 37, Castle-street, Edinburgh. The complainers asked interdict against the respondents erecting poles and wires and other apparatus in connection with their electric tramways within such distance as would endanger the complainers' wires and apparatus, or interfere with or impede the telephonic communication along or by means of the same, and also from turning on electric current within such distance as would endanger the complainers' wires and apparatus. The complainers relied on certain sections of the Tramways Act of 1870, incorporated in respondents' special Act, as affording protection against interference with their telephone wires, while respondents contended that these provisions were not applicable, in respect that tramways worked on the trolley system of electric traction were not in contemplation by the Legislature when the Act of 1870 was passed, and they founded upon certain sections in their special Act and regulations made by the Board of Trade in pursuance thereof as defining the measure of protection afforded to the complainers. His Lordship, in respect of an arrangement between the parties, whereby the alterations on the complainers' wires are to be carried out by them under reservation of their claims against the respondents if liability therefor should ultimately be established, refused the note.

TRAMWAY FARES.

A test case of considerable interest was tried at Liverpool on Wednesday, when Colonel John Pilkington was summoned for non-payment of 1d. excess fare while riding on a Corporation car.

Defendant took a 1½d. ticket, but continued to travel beyond that stage, tendering the conductor an additional ½d. There are no ½d. stages on the system, and the conductor asked for 1d., which defendant refused to pay, contending that he was only travelling to a point for which the fare was 2d.

The magistrate dismissed the summons, taking the view that the regulation was only designed to prevent wilful avoidance of payment. He added that "the mere fact that the undertaking did not possess a ½d. ticket was not defendant's fault."

COMPANIES' MEETINGS AND REPORTS

WHITECHAPEL AND BOW RAILWAY.

A special meeting of this Company was held last week for the purpose of raising fresh capital.

Mr. A. L. STRIDE presided, and announced that the proxies of the London, Tilbury, and Southend Railway Co. and of the Metropolitan District Railway, who jointly owned the line, were in favour of the increase of capital. He thereupon moved that, under the powers of the Whitechapel and Bow Railway Act, 1905, there should be created additional capital to the amount of £150,000 by the issue of 15,000 new ordinary shares of the Company of £10 each, and that the directors should be at liberty, with the consent of the London, Tilbury, and Southend Railway Co. and of the Metropolitan District Co., to attach to 6,000 of the said shares—in lieu of the rights attached to ordinary shares—a dividend in priority to the ordinary shares of the Company, at such rate not exceeding £4 per annum as the directors might determine.

Mr. GRIFFITH MURRAY seconded the resolution, which was carried unanimously.

A resolution was then passed authorising the issue of the shares at such times, on such terms, and in such manner as the directors might think advantageous to the Company.

A third resolution sanctioned the exercise by the Company of their borrowing powers to the extent of £50,000, by the creation and issue of debenture stock as the directors should think fit, and at an interest not exceeding £4 per annum.

This resolution was moved by the CHAIRMAN, seconded by Mr. J. R. HOARE, and carried unanimously.

YORKSHIRE ELECTRIC POWER.

The half-yearly report, to be submitted at the meeting of the Company on the 26th inst., states that since the last report the first two turbo-generators have been erected in the Thornhill power station, and are now working. It is expected that the third turbo-generator, which will complete the present order for generating machinery, will be installed during the autumn. The equipment for sub-stations at Thornhill, Mirfield, Gomersal, and Pudsey is practically completed and is now in use. The transmission mains referred to in the January report have been laid, and the distribution mains and service equipment necessary to connect consumers are being proceeded with. A supply of energy was given to the Mirfield Urban District Council on July 7, and to the Pudsey Corporation on Aug. 23, and the supply to other consumers is being given as their installations are ready. It is satisfactory to report that it has been possible, without serious opposition, to arrange clauses in the parliamentary Bills affecting the Company, by which the interests of the Company have been protected.

At the conclusion of the general business an extraordinary meeting will be held to consider the desirability of passing, and, if deemed expedient, to pass necessary resolutions to obtain further moneys to develop the Company, and carry the transmission mains into other districts in which a good demand for power is anticipated.

The meetings will be held in Ravensthorpe to give shareholders the opportunity to visit the power station and other works of the Company in the neighbourhood.

LANCASHIRE ELECTRIC POWER.

The tenth ordinary meeting of the Company was held at Broad Sanctuary-chambers, Westminster, on Thursday, the 31st ult., Mr. F. E. Gripper presiding.

The CHAIRMAN said he was pleased to be able to state that they were on the eve of the commencement of supply. Their main cables were practically laid to Swinton and Pendlebury and Westhoughton, and the Company would be in a position to supply those urban districts during the coming month. A provisional order had been obtained for the urban district of Tottington, and the laying of their main cable through that district and on to Bacup was well in hand, and by the end of this, or early in the coming year, it was expected that the Company would be fully working.

UNITED ELECTRIC CAR.

The report for the year ending June 30, to be submitted at the general meeting on the 21st inst., states that the works have been efficiently maintained as regards buildings and machinery, the cost of which has been charged against revenue. After paying debenture interest, amounting to £2,500, and charging £4,315. 6s. 2d. for depreciation, the profit for the year is £15,188. 18s. 9d., to which is added £2,873. 1s. 11d. brought from last year, making a total of £18,062. 0s. 8d. The directors recommend that this amount be dealt with as follows: dividend of 6 per cent., less income tax, for the year ending June 30, 1905, £12,000; carry to general reserve, £2,000; and carry forward to next year, £4,062. 0s. 8d.

NEW COMPANIES REGISTERED.

Burgess Hill and District Electric Supply Co.—Registered Aug. 29. Capital, £5,000 in £1 shares (2,000 5 per cent. non-cumulative preference). Object: to adopt an agreement with W. Simms, trading as Simms and Co., electrical engineers, of Hamilton-road, Felixstowe, and to carry on at Burgess Hill and elsewhere in Sussex the business of an electric light and power company, and that of electrical and general engineers, electricians, manufacturers of and dealers in all kinds of electrical apparatus and accessories, etc. The first directors (to number not less than four nor more than seven) are W. H. de la Tour d'Auvergne Findlay, H. Aldrich, W. B. Welch, and A. G. Davey. Registered office: Mr. Thomas Sinnock's Offices, Railway-approach, Burgess Hill, Sussex.

Kapar Para Rubber Estates Co., Limited—Capital, £50,000, in £1 shares. Object: to carry on the business of rubber and general produce planters, growers, manufacturers, and merchants, etc. Registered office: 81, Gracechurch-street, E.C.

Lancashire Rubber Co., Limited.—Registered Aug. 30. Capital, £3,000, in £1 shares. Object: to carry on the business of buyers and sellers of old and new rubber or similar substances, manufacturers of and dealers in rubber articles of all kinds, and of chemical and scientific apparatus and appliances. Registered office: 86, Cross-street, Manchester.

Liens Registered.

Fife Electric Power Co., Limited.—A trust deed, dated Aug. 15, securing £15,000 debentures, created by resolutions of June 6 and Aug. 15, 1905, has been registered. Property charged: the company's general assets, present and future, including uncalled capital, with certain collateral security. Trustees: R. E. Walker, Lieut.-General Sir Richard H. Sankey, and H. Mungall.

Scottish House-to-House Electricity Co., Limited.—Charge registered Aug. 31 for £1,600 and 6 per cent. interest to the County of London Electric Supply Co.; charged on the undertakings and all the property and assets, present and future, including the uncalled capital.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Stockport—Tenders are required for supply and laying of cables. Tenders by Sept. 14.

Oban—Tenders are required for supply and laying of feeders and mains. Tenders by Sept. 11.

Florianopolis (Brazil).—The Municipality require tenders for the lighting of the town by Oct. 2.

Plasencia (Spain)—The municipal authorities require tenders for an electric lighting installation. Tenders by Sept. 15.

Olympia 1905 Exhibition.—The Executive Committee invite tenders for the loan or hire of 300-kw. direct coupled steam set.

Madrid.—The Public Works Department require tenders for the construction and working of an electric tramway in Zaragoza. Tenders by Sept. 12.

Pontypridd.—The Urban District Council invite tenders for (Section B) overhead equipment for tramways; (C) cables for tramways. Tenders by noon on Sept. 30. See advertisement.

Salford.—The Corporation invite tenders for the wiring of the new Council Schools, Devonshire-street, Broughton. Tenders to the Director of Education, Chapel-street, Salford, by 14th inst.

Bishop's Stortford.—The Urban District Council invite tenders for lighting such of the public streets as are at present lighted, for two or three years from Sept. 30. Tenders by 4 p.m. on Sept. 25.

Edinburgh.—Tenders are invited for the electric lighting installation at the mortuary buildings, High School Yards, Edinburgh, for the Lord Provost, Magistrates, and Council. Tenders by Sept. 11.

Burton-upon-Trent.—The Corporation invite tenders for the supply and laying of feeder cables, conduits, and other works in connection therewith. Tenders by noon on Sept. 25. See advertisement.

Alicante (Spain).—The Harbour Board (Junta des Obras del Puerto) require tenders for two electric cranes, capable of lifting 10,000 ko. and 1,500 ko. respectively. Tenders by Sept. 15. Estimate, 107,010·10 pesetas.

Chelmsford.—The Town Council invite tenders for lighting the public streets and public clock within the borough with electricity, gas, or other illuminating power for three or five years from March 25, 1906. Tenders by Sept. 8.

Paris—The Waterworks Department of the Municipality require tenders for supply and erection of motors, pumps, and generators for the proposed waterworks at Chantilly. For particulars apply to above authority. Tenders by Oct. 12.

Ipswich.—The Guardians invite tenders for supply and erection of a dynamo and motor (to be made by Crompton and Co.), a battery booster, and alterations and additions to the main switchboard at the workhouse. Tenders by 10 a.m. on Sept. 14.

Stalybridge.—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery, and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

Pembroke (Ireland).—The U.D.C. invite tenders for electricity supply mains, arc lamps and pillars, house meters, and switchboard panels. Tenders to Mr. J. C. Manly, Town Hall, Ball's Bridge, Co. Dublin, by 10.30 a.m. on Sept. 22. See advertisement in last issue.

Dublin.—The Lighting Committee invite tenders for the supply of (*a*) sub station switchboards, transformers, etc.; (*b*) extra high-tension and low-tension mains. Tenders to Chairman of the Lighting Committee, 3, Cork-hill, Dublin, by Sept. 18. See advertisement in last issue.

Linlithgow (Scotland).—The Uphall and Broxburn District Lighting Committee invite tenders for the supply and erection of one suction gas-producer plant of 80 b.h.p. capacity; one 80-b.h.p. gas-engine; one 52-kw. dynamo; one automatically-reversing motor booster, two 280-ampere-hour storage batteries, switchboard, cables, meters, etc. Tenders to Mr. J. G. B. Henderson, county clerk, Linlithgow, by 12 noon on 18th inst.

Digitized by Google

London, S.W.—The London County Council invite tenders for the manufacture, supply, and delivery of 34 steel single-deck tramcar bodies; maximum traction swing bolster trucks for 34 electric cars; complete electrical equipments for 34 cars; or, alternatively, 34 steel single-deck cars, with trucks and equipments complete. Tenders by 10 a.m. on 29th inst.

Erdington.—Tenders are required for the construction of Section No. 1 of the Erdington tramways, comprising the laying of the permanent way, including copper bonding, wood block paving, and other works incidental to the laying of about 2¼ miles of double-track tramway, for the Tramway Committee. Tenders to the joint engineers, Mr. Robert Green (of Messrs Pritchard, Green, and Co.), of 37, Waterloo-street, Birmingham and Mr. Herbert H. Humphries, engineer to the Council, Public Hall, Erdington.

Municipal Board of Mussoorie (India).—The Municipal Board invite tenders for the supply, delivery, and erection at sites, in complete working order, of the following plant: (*a*) steel power pipes; (*b*) water-motors; (*c*) alternators with exciters; (*d*) switchboards with instruments and apparatus; (*e*) transformers; (*f*) induction motors; (*g*) pumps; (*h*) workshop machines. Also for the supply and delivery of the following: (*a*) bare copper wire for overhead mains; (*b*) insulators and lightning arresters; (*c*) arc and incandescent lamps; (*d*) telephone equipment; (*e*) workshop tools; (*f*) general stores. Specifications, form of tender, and general conditions can be obtained on application to Mr. C. H. Shanan, municipal electrical engineer, Municipal Office, Mussoorie, India (telegraphic address, Shanan, Mussoorie), on payment of a deposit of Rs.75 (£5), which amount will be returned on receipt of a bona fide tender. Tenders by Oct. 23.

RESULTS OF TENDERS.

Warrington.—The Council have accepted the tender of Johnson and Phillips for 12 months' supply of paper-insulated lead-covered cables.

Ilford.—The Urban District Council have accepted the tender of W. T. Henleys Limited, London-wall (per schedule), for supply of ·4in. and ·25in. concentric cable.

Luton.—The tender of Triumph Stoker, Limited, of 39, Victoria-street, London, S.W., has been accepted for mechanical stokers for the Corporation electricity works.

Pekin.—The tender of Bruce Peebles and Co. has been accepted for 1,500-h.p. electrical plant for the complete equipment of the railway shops of the Imperial Chinese Railway, Pekin.

Dover.—The Town Council have accepted the tender of W. Cory and Son, Mark-lane, E.C., for large Welsh coal at 16s. 11d. per ton, and small at 11s 6d., for their electricity works for 12 months.

Neath.—The Rural District Council have accepted the tender of Johnson and Phillips, Old Charlton, Kent, for low-tension cables and street-lighting for the districts of Skewen, Melincrythan, Cadoxton, and Aberdulais.

South Shields.—The Town Council have accepted the tender of W. Underwood and Bro., Hope-street and Railway-street, Dukinfield, at £1,070, for the laying of the permanent way for the service line to the car-sheds at Dean-road.

Oakeley Quarries (North Wales).—Messrs. Bruce Peebles and Co have secured the contract for supplying motors for the Oakeley Quarries, North Wales, for 2,000 h.p., ranging from 25 h.p. to 125 h.p., for hauling, compressing, winding, etc., the power to be taken from the North Wales Power and Traction Co.'s mains.

Limerick — the Technical Education Committee have received the following tenders for electric lighting of the municipal technical schools, 69 and 70, George-street, Limerick:

69 and 70, George-street.

Ampere Co., 44, Fleet-street, Dublin	£97	10	0

69, George-street.

Coates, Dublin (accepted)	35	10	0
Portley Bros., Limerick	39	0	0

70, George-street.

Coates	45	0	0
Portley Bros. (accepted)	41	0	0

Fulham.—The Borough Council have received the following tenders for the erection of a boiler-house, cable-shed, and stores at the electricity works, Townmead-road:

Borough Surveyor*	£4,000	0	0
Perry and Co.	4,656	0	0
A. Hudson and Co.	3,550	0	0
S. E. Moss and Co.	4,300	0	0
A. Lawrence and Son	4,545	0	0
H. Windsor and Co.	5,083	7	2
Higgs and Outhwaite	4,613	0	0
W. H. Hyde	3,810	0	0
W. J. Fryer and Co.	5,190	0	0
B. E. Nightingale	4,077	0	0
Leslie and Co.	4,495	0	0
F. and G. Foster	4,278	0	0

* Recommended for acceptance.

The Establishment Committee also recommend for acceptance the following tenders for the supply and delivery of steam coal to the electricity department during the year ending June 30, 1906: Charrington, Sells, Dale, and Co., 2,000 tons of Albert nuts, 11s. 11d. per ton; Crynant Colliery, Limited, 1,000 tons Crynant nuts, 14s. 4d. per ton; Cory Bros. and Co., 1,000 tons Monmouthshire washed beans, 14s. 1d. per ton.

Motor 'Buses.—The trial trip by motor 'bus to Brighton, referred to in our last week's issue, is considered satisfactory, and further runs will be made. If these prove satisfactory, there will be a regular service next year.

BUSINESS NOTES.

TRACTION.

Perth.—A special meeting of the Town Council was held in private last week upon the question of liability for the cost of heightening the cars.

Blackburn.—The Corporation tramways show a net profit of £800 on the past quarter, as compared with a loss of £400 on the corresponding three months last year.

Carshalton.—The Urban District Council have received from the British Electric Traction Co. several plans regarding street widenings, which have been referred to committee.

Doncaster.—At the meeting of the Town Council it was reported that the receipts from the Oxford-street route for a fortnight were 1s. 2d.! The service will probably be discontinued.

Manchester.—At Wednesday's meeting of the Corporation, a resolution that a scale of reduced fares for workmen be formulated with a view to relieving congested areas was formulated.

Electrical Signalling.—The installation of an electrical system of working points and signals has been adopted at Didcot, this being the first installation of the kind on the Great Western system.

Oxford.—The City Council decided on Wednesday to purchase and electrify the tramways, a surface-contact system to be used in the High-street and in the centre of the city for æsthetic reasons.

Motorcars and Westrumite.—The Automobile Club intend to have the whole of the course (over 40 miles) in the Isle of Man for the Touring Trophy Race on the 14th inst. treated with Westrumite.

Broughty Ferry.—The work of reconstruction is being rapidly pushed forward by Messrs. J. G. White and Co., and it is expected that the system will be completed by the first week in December. There is some talk of the erection of a garden city *en route*.

Newcastle.—The Corporation have decided to apply for a provisional order for an extension from Pilgrim-street to New Bridge-street. In reply to a question, the Chairman of the Tramways Committee thought the present time inopportune for the adoption of ½d. fares.

American Methods.—A new railway training school has been established at Elmira, N.Y., on distinctly practical lines. Railway telegraphy is part of the training, and in this department a switch-line enables the school to cut in on the regular dispatchers' wire on the Erie main line, allowing advanced pupils to have the practice of copying real business.

Rochdale.—The traffic receipts on the Corporation system for the week ended on Saturday are the highest yet reached, being £80 in excess of the previous week, the takings for which were the largest returned up to that date. The passengers carried numbered 13,758 more than for the previous week, the total being 194,772, and the receipts £1,083 against £1,002.

Erith.—The new cars are meeting with excellent support, the takings for the first five days being: Saturday, £71. 2s. 8d.; Sunday, £61. 5s.; Monday, £29. 4s. 9d.; Tuesday, £25. 4s. 1½d.; Wednesday, £25. 18s. There have been complaints as to the irregularity of the service, this being attributable to the narrowness of some of the roads, which will probably be widened.

Bath.—A trial trip was made last week with the motor 'buses with which the Bath Electric Tramways Co. propose to link up their system with the outlying districts of Box, Corsham, Bradford-on-Avon, etc. The Milnes-Daimler Co. have supplied the first of six 'buses. The trial proved satisfactory, and it is expected that the service will be inaugurated in a fortnight's time.

Glasgow.—An accident occurred on the Corporation system on Saturday, when a lorry and car collided. The road was narrow, with a steep incline, and greasy through showers. The lorry pulled up in front of the car, which there was not time to stop. The two drivers and several passengers were injured, and the car penetrated an advertisement hoarding and fell into a field.

Tourist Cars.—The Brighton tourist tramcars appear to have proved a profitable venture. Since July 3 6,512 passengers have been carried round the town on these cars. The fares have amounted to £312, which gives an average of 34·34d. per car mile. The tramways engineer and manager points out that the receipts from these cars are about three times the amount obtained from the remainder.

London County Council.—An important development of the London County Council tramway system has recently been entered upon by the construction of a line from New Cross to Lewisham. Such rapid progress is being made that the line is likely to be finished very shortly. It is probable that an extension will be made from Lewisham to Catford, and ultimately to Bromley and Bickley.

Ramsgate.—The secretary of the Isle of Thanet Electric Tramways and Lighting Co. has issued a notice to the shareholders stating that, in view of the recent accident at Ramsgate, the directors have decided to defer making any payment on account of the second half-year's preference dividend, usually paid on Sept. 1, until after the accounts for the company's financial year, which ends on Sept. 30, are made up.

Batley.—The contractors (Messrs. Dick, Kerr, and Co.) have pushed on so rapidly with the work of reconstruction between Batley and Dewsbury that the steam trams on the Bradford-road are to cease running in order that the reconstruction may be proceeded with. The paving has been carried on with such dispatch by the Batley Corporation workmen that they will be able to follow Messrs. Dick, Kerr, and Co. to the Batley and Birstall portion almost immediately.

Halifax.—The Board of Trade report on the Corporation tramway extension to West Vale states that there is one very steep gradient

Digitized by Google

down Salterhebble-hill of 1 in 9·6 for a length of one furlong, and great care must be exercised in working cars down it. The report says the cars must be fitted with track brakes in addition to the ordinary brakes, and also with a special device for preventing cars from running backwards. The rails are to be kept well sanded in damp weather.

Sale.—At the meeting of the Sale Council it was decided to inform the Stretford Council, regarding the improvement of Crossford Bridge, that Sale's offer of £250 was conditional upon the preparation of a scheme for the widening of the bridge and its approaches on both the Lancashire and Cheshire sides of the river. The Sale Council, it was pointed out, was not blocking the tramway scheme in any way. The Stretford Council had written that the Manchester Corporation were desirous of pushing the scheme forward before the winter months.

Worcester.—The tramway company offer to extend the tramway along the Malvern road as far as the Brunswick Arms, on condition that the Council agree to the rails being laid on concrete and a single line of setts placed lengthwise along each side of the rails, the remainder of the paving to be of macadam; the Council undertaking to maintain the track, leaving the company responsible for the rails, etc., and offering to maintain the paving of the track for £20 per annum. The Streets Committee recommend that these terms be agreed to.

Hastings.—At the meeting of the Town Council, Councillor Harden asked the chairman of the Roads and Buildings Committee whether he was aware that the roadway on some parts of the tramway route, particularly in Silverhill and Hollington, was in a very unsatisfactory condition, and whether the committee would urge the company to expedite the reinstatement and repair where necessary. In reply, the Chairman stated that he had been over the roads on that and the previous day, and with two small exceptions, which were being attended to, the roads in that district were the best in the borough.

Preston.—For the year ending March 31 last the Corporation cars showed a net profit of £1,575. The receipts were £22,922 and the working expenses £12,030, while interest and sinking-fund charges absorbed £5,130 and £4,206 respectively. The balance of £1,575 has been carried to reserve. The earnings work out at an average of 10·64d. per car mile. The actual working expenses, exclusive of interest and sinking-fund charges, work out at 5·59d. per car mile. The earnings of all the routes appear to be satisfactory with the exception of Ribbleton-lane, the earnings of which were only 5·79d. per car mile.

Hanley.—At the meeting of the Town Council the following minute of the Tramways Committee was passed: "That the plan showing proposed double line of tramway joining up the Broad-street, Victoria-square, Shelton Church, and Howard-place loops or passing places be approved, and that the suggestion of the borough surveyor with regard to that part of the line between the Broad-street and Victoria-square loops, as laid before this committee on July 26, 1904, and confirmed by the Council on Aug. 30, 1904, be carried out." The Board of Trade have signified their approval, and the company have entered into a contract for the work.

Rhondda.—Some time ago the Board of Trade Commissioner conducted an inquiry in reference to the Council's tramway scheme. The Council have spent about £6,000 in the endeavour to get a provisional order, and at a public meeting of ratepayers a resolution was almost unanimously passed backing up the Council in its endeavour to provide the Rhonddas with a complete system of tramways. To this enterprising proposal there has been persistent opposition, and the report of the Commissioner has been awaited with considerable concern. This report has just come to hand, but for the moment its contents have not been disclosed. A meeting of the Council is to be held to-day, when the report will be made public.

Colchester.—The accounts for the 12 months ending July 27 show that there had been expended on traffic expenses £3,414. 16s., for general expenses £1,134. 10s. 2d., for general repairs and maintenance £964. 9s. 2d., for power expenses (cost being put at 1½d. per Board of Trade unit) £2,664. 5s. 10d.—total operating expenses, £8,178. 1s. 2d. The income included £11,270. 5s. 9d. from ordinary passengers, £33. 8s. from special cars, £424. 4s. by advertisements, £42. 12s. 6d. carriage of luggage, £101. 3s. 2d. interest on surplus revenue, and £26. 0s. 6d. rent. A gross profit of £3,719. 12s. 9d. has been carried to the revenue account, but allowance has been made for seven months' capital charges only.

Belfast.—At last week's meeting of the Corporation the city accountant submitted a statement showing that the total capital expenditure on the tramway undertaking was £521,116. 6s. It was decided to agree to an extension of the contract with Mr. J. W. Courtenay for the advertising on the cars for an annual payment of £3,000. The whole of the system is expected to be opened to the public by the middle of November. The Tramways Committee are to be approached by the Guardians, who have received an intimation from the National Telephone Co. that they cannot continue the telephone service to the workhouse because of the refusal of the Tramways Committee to allow the necessary cable to be carried across the street.

Derby.—The Walbrook-road extension of the Corporation electric tramway system was opened on Tuesday afternoon. Prior to the route being opened to the public it was officially inspected by the Board of Trade inspector, Major Pringle, who found everything in satisfactory order. Major Pringle travelled over the route on a special car, accompanied by Alderman R. W. Sprigg (chairman of the Tramways Committee), Councillors J. W. Gandy, J.P., C. Boam, and A. Simpson, the borough surveyor (Mr. John Ward), the electrical engineer (Mr. T. P. Wilmshurst), the manager of the tramways (Mr. F. Harding), and the assistant borough surveyor (Mr. C. A. Clews). The extension is about half a mile in length, and runs from the bottom of Dairy House-road to the Cavendish Hotel, thus linking the Pear Tree and Upper Dale routes.

Dover.—A trial trip was run over the new River tramline last week. There was no trouble in either the ascent or descent of the inclines on the route. The trial was for the testing of the equipment, and the athletic ground was as far as the car could travel, the ballasting and pitchering, as well as the electric equipment, being as yet incomplete beyond that point. There is a double line of rails laid all the way, but only one line was cleared for that run, there being as yet a little more work to be done on the surface of the track, both on Crabble-hill and down the approach to the Lower-road. The overhead wires are all up, but the bonding of the rails is still in progress. Most of the ballasting and pitchering between the rails has yet to be done on that section, and a few lengths of rails at the terminus as yet want the concrete base. The work on this section is now being pushed on with a view to an early opening for traffic. The Corporation have purchased four additional cars for the extension.

Motorcar Commission.—A Royal Commission on motorcars has been appointed, consisting of Viscount Selby (chairman), the Marquess of Winchester, Sir David Harrel, Sir W. B. Forwood (chairman of the Lancashire Quarter Sessions), Mr. Edward Richard Henry (Commissioner of Metropolitan Police), Mr. Wm. John Mure, and Mr. Horace Cecil Monro (one of the assistant secretaries of the Local Government Board). The Commissioners are instructed to inquire and report as to (1) the working of the Motorcar Acts, 1896 and 1903, and of the regulations under them; (2) the law and practice in relation to motorcars in the principal foreign countries; (3) what amendments, if any, should be made in the Motorcar Acts and the regulations under them; (4) the injury to the roads alleged to be caused by motorcars; and (5) whether any, and, if so, what, additional charges should be imposed in respect of motorcars, and how any money thus raised should be applied. Full power is granted to the Commissioners to call evidence from any quarter whence it is obtainable, to examine books and documents, and to personally inspect whatever places they may deem advisable. They are instructed to report "with as little delay as possible." Captain Charles Clive Bigham is appointed secretary to the Commission.

Penmaenmawr.—At a meeting of the Urban District Council a proposition was moved that a public meeting be called to consider whether an electric railway should be made to the top of the Green Gorge, 1,200ft. above the sea. The mountain lands to which such a line would give access were, said the councillor who moved the resolution, the one asset of Penmaenmawr, and they had never been properly exploited. Although the Council had almost reached the limit of their borrowing powers, in five years loans would be paid off which were now a considerable burden, and they might, perhaps, get from the local landowners and others loans without interest with which to make the line, such loans to be repaid at the end of five years, when the Council would be in a position to borrow the money. A 50-h.p. engine would generate current sufficient to work the line during the day and light the fine new promenade at night, and they had a convenient site for the power-house adjoining the railway station. The chairman expressed the opinion that the line suggested was the one thing needed in Penmaenmawr. The resolution was carried on the understanding that the committee would draw up a rough idea of the cost, route, etc., for presentation to the public meeting, incurring, however, only a small expense in connection with these preliminaries.

Heywood.—As the result of a lengthy conference between representatives of the Heywood and Rochdale Tramways Committees, last week terms were agreed upon for working the lines in Heywood, the arrangement being subject to the confirmation of the respective authorities. Heywood will pay to Rochdale 4½d. per car mile run as working expenses. Receipts earned in Heywood borough will be handed over to Heywood, and those earned in Rochdale will be kept by the Rochdale authority. The chief point of contention has been in regard to the division of the 3d. through fare. It was originally proposed that 2d. of this should come to Rochdale and the remaining 1d. be paid to Heywood. To this the Heywood representatives offered strong opposition on the ground that the distance between the Rochdale boundary and the Heywood Market-place is three furlongs over a mile, which is usually regarded as a 1d. stage. After a very lengthy discussion the Rochdale representatives conceded the point and agreed that the division of the through fare should be on the basis of car mileage run in each district. Bury had agreed to a joint sub-committee to decide upon the details of the service to be run, but Rochdale desired, for the first six months after opening, an absolutely free hand in working the section, and to this Heywood consented. The delegates propose that the agreement shall be for two years. The reconstruction of the track in Heywood is proceeding as rapidly as possible, and it is hoped to have the whole of it, from Heap Bridge to the Rochdale boundary, completed in November. No cars will run before then, as the Heywood electricity station will not be ready to supply current until after the whole of the track is finished.

Llandudno.—The extension of the powers of the Llandudno and Colwyn Bay Electric Railway Co. terminated on Aug. 31, and the company are negotiating for a further six months. The Urban District Council instructed a committee to consider the company's application for consent, and at the meeting of the Council last week the committee recommended the Council to support the application by the company, on condition that the company deposited £1,000 with the Council's bankers on or before Sept. 14, such sum to be refunded to the company within six months on the production to the Council of two certificates, one from the Board of Trade to the effect that the whole of the work necessary to complete the undertaking between the promenade at Rhos-on-Sea and the corner of Mostyn-street and Gloddaeth-street, Llandudno, had been carried out to the satisfaction of the Board; and the second, that of the surveyor to the Council, to the effect that the terms of the existing agreement, so far as they related to the construction of the light railway between the points stated, had been duly observed. Should these certificates not be forthcoming within the six months, then the £1,000 would be

Digitized by Google

forfeited to the Council. In the event of these terms not being complied with on or before the 14th inst., the committee recommended that an objection to any extension be lodged with the Board of Trade. It was ultimately decided that the deposit of £1,000 should be returned to the company on satisfactory proof that £9,000 had been expended between Rhos-promenade and Gloddaeth-street. If the two certificates referred to are not forthcoming at the end of the six months, all rails, plant, etc., in the streets of the town are to be the absolute property of the Council. The surveyor reported that the rails and sleepers had been laid over 2½ miles.

Inquest.—At the London Hospital Mr. Baxter held an inquiry concerning the death of John Thomas Evans, aged 37 years, a bricklayer, who died from shock and severe burns received at the electrical sub-station, Whitechapel, in connection with the Underground Railway. It appears that on the day in question the men entered the high-tension chamber for the purpose of removing some iron floor plates, having previously taken some away two days before. They had lifted the plate from the ground when there was a loud report followed by a flash like lightning and the men were at once enveloped in flames. At the time it happened the electrician and the chief operator were talking together at the station door. In the course of their evidence they both said they did not see the men go into the tension chamber, neither had they any right to do so without permission. At the time of the occurrence half the chamber would be alive and the other half dead. The iron plate must have touched the feeder switch to make the electrical circuit. Henry Tuppin, the foreman, said he gave the orders for the men to fetch the plates. He was not aware that it was necessary to obtain permission to enter the room, neither was he aware of any special danger. He had never received any special instructions, and knew nothing about electricity. After further evidence the coroner, in summing up, remarked that it certainly was not right that men should be allowed to go into a place surrounded with all manner of dangers. The whole thing seemed carried on with great carelessness, and there were not sufficient precautions taken to prevent accidents. He thought the tension chamber ought to be kept locked, and notices posted at the entrance of the station warning people of the danger. It was a new system of working, and no doubt better precautions would be taken in the future. The jury expressed concurrence with the coroner's observations, and added that there had been negligence in the matter. In returning a verdict of accidental death, they added that sufficient care had not been taken to prevent the men entering the chamber, and they desired the coroner to draw the attention of the directors to the matter to prevent similar accidents.

LIGHTING AND GENERAL.

Newquay.—A light and power company has been registered and a site for the generating station acquired.

Hayward's Heath.—The local electric supply company has been asked by the Urban District Council to submit terms for electric lighting.

Liversedge.—The Urban District Council have decided to canvass the inhabitants with a view to ascertaining the probable number of lighting customers.

Chelsea Electric Supply Co.—The directors have declared an interim dividend on the ordinary shares for the half-year to June 30 of 2s. 3d. per share, or at the rate of 4½ per cent. per annum.

Newcastle.—The Tramway Committee having been allowed to amend their offer of £15 10s. to £11 per lamp for lighting certain streets, the gas company are to have a similar option.

Hammersmith.—The Borough Council has given notice that in future the price of electricity for lighting purposes to the residents of the borough will be reduced to a uniform rate of 3d. per unit.

Telegraphic Communication with Japan.—The Great Northern Telegraph Co. notifies that traffic with Japan is subject to delay, owing to interruption of the cables between Shanghai and Nagasaki.

London Gazette.—A receiving order has been made out on debtor's petition in the estate of William Jefferson, electrical engineer, carrying on business as Jefferson and Co. at 69, Skinnergate, Darlington.

Barnsley.—The Town Council have decided to make application to the Local Government Board for sanction to borrow the sum of £3,000 for the extension of mains and services and the purchase of meters.

South Metropolitan Electric Light and Power Co.—The warrants for the payment of the dividend on the 7 per cent. cumulative preference shares payable on the Aug. 31 have been posted.

Bridgend.—The District Council, on the recommendation of the Lighting Committee, have written to the South Wales Electrical Power Co. with regard to the fluctuations in the public lighting of the town.

Hove.—The suburb of Aldrington last week had an electrical supply inaugurated, the energy being supplied from the Brighton Corporation's new power-house, while the Hove Corporation undertakes the distribution.

Removal.—The Industrial Engineering Co., of Newton Ironworks, Hyde, manufacturers of electric dynamos, motors, gas-producer plants, and pneumatic tools, have removed their head offices to 12, Exchange-street, Manchester.

Ormskirk.—The Urban District Council propose to lease their prospective electricity undertaking, for which they have applied for sanction to a loan of £25,000, to the National Electric Construction Co., but the Board of Trade refuse their consent. The Board intimate that the Council should seek further parliamentary powers.

Turbines.—Following upon the electrification of various spinning and weaving mills in Lancashire, it is announced that turbines are to be tried in certain new factories in course of erection. The Kearsley Spinning Company have decided to place engines of the turbine type in the large mill they are building near Bolton, which is to accommodate close upon 100,000 spindles.

Horsham.—From the accounts of the Urban District Council's undertaking for the year ending March 31 we observe that the receipts amounted to £2,397 and the working expenses to £1,379, showing a balance of £1,018. Interest and sinking fund charges about £779 and £564 respectively, so that there is a slight deficiency. The figures for supply, however, evince a decided upward tendency.

Eastbourne.—The Corporation intend to have their pound of flesh—*i.e.*, the £10 they have agreed to contribute to the Olympia Electrical Exhibition is not to be treated as a donation, but is to be met by an equivalent in ticket. Apparently the Government have refused any payment for telephone wayleaves, and the Association of Municipal Corporations is to be communicated with in view of united action.

New Premises.—Messrs. W. F. Stanley and Co., 4 and 5, Great Turnstile, Holborn, notify that they have extended their business by taking additional premises at 286, High Holborn, abutting on their Great Turnstile works. They have transferred their showrooms and sale branch of surveying, drawing, mathematical, and optical instruments to the new address, where business will be conducted between 9 a.m. and 7 p.m. (Saturdays, 9 a.m. to 2.30 p.m.). Export and country orders should be sent to 4 and 5, Great Turnstile, as before.

Preston.—At the meeting of the Town Council the chairman of the Streets Committee moved the adoption of the committee's recommendation that gas be substituted for electricity in the public streets. He stated that, as against the £825 per annum for electricity, the cost for gas would be less than £400 a year. Councillor Andrew complained that no intimation of this proposal had been made to the sub committee of the Tramways Committee, who had sanctioned a scheme for the electric lighting of the power station and the destructor buildings, and eventually it was agreed to refer the matter to a joint meeting of the sub-committees of the Tramways and Streets Committees.

Bermondsey.—At Tuesday's meeting of the Borough Council the electric estimates for the year ending March 31 next were adopted. Generation charges are fixed at £6,112, or ·73d. per unit sold, as against £4,032 spent in the year ending March 31 last; distribution, rates and taxes, management, salaries, establishment charges, etc., £2,538 (3d. per unit sold), as against £1,182 in the last financial year; interest and instalment of loans £3,976, as against £3,164; and other charges a total of £13,906, as against £10,875. The receipts are estimated at £16,203, as against £12,015; the surplus at £2,302. As from Oct. 1 the charge for power purposes will be reduced to 1½d. per unit for the first four hours' average daily use of the maximum demand and ¾d. after; for lighting 6d. per unit the first hour and 2d. after, flat rate 4½d.; and the committee express the hope that they will be able to make a rebate of ½d. per unit on the street-lighting. The units generated in July, 1905, were 135,500, as against 55,054 in 1904. The London County Council have agreed to advance £6,796 for extensions in lieu of the £7,277 applied for.

Stock Exchange.—The committee has appointed the 13th inst. as a special settling day for Durham Collieries Electric Power Co.'s 85,102 6 per cent. cumulative preference and participating shares of £1 each, fully paid, Nos. 1 to 85,102; London United Tramways (1901) further issue of £300,000 4 per cent. first mortgage debenture stock. The committee has ordered the following securities to be quoted in the official list: London United Tramways (1901) further issue of £300,000 4 per cent. first mortgage debenture stock; River Plate Electricity Co.'s 119,691 ordinary shares of £1 each, fully paid, Nos. 1 to 119,657 and 120,521 to 120,507. 100,000 6 per cent. non-cumulative preference shares of £1 each, fully paid, Nos. 1 to 100,000, and £194,684 5 per cent. debenture stock; Anglo-Portuguese Telephone Co.'s £50,000 5 per cent. first mortgage debenture stock; Kalgoorlie Electric Power Co.'s £100,000 5 per cent. A debenture stock, and £100,000 6 per cent. B debenture stock; Rosario Electric Co.'s 12,000 6 per cent. cumulative preference shares of £5 each, fully paid, Nos. 1 to 12,000, and 8,000 6 per cent. cumulative preference shares of £5 each, £4 paid, Nos. 12,001 to 20,000.

St. Annes.—At the meeting of the Urban District Council the electrical engineer made the following report for July: Units sold during July, 55,855; units sold to July 31, 1905 175,243; equivalent to 8-c.p. lamps connected, 18,908; units sold per 8 c.p. lamps connected, 2·54; maximum load—lighting 200 kw., traction 330 kw.; total number of consumers, 361. Six applications have been received for the equivalent of 286 8-c.p. lamps. Arrangements have been made with the tramway company for use of feeder cable and installation of the balancer in the company's sub-station, and an annual rent of £50 has been agreed upon. It was reported that the tramways company were exceeding the agreed maximum demand of 400 amperes. The Council decided not to take any steps in this connection during the present busy season. It was decided to reply to complaints as to emission of smoke from the electricity works that all precautions for minimising the smoke had been taken. A letter was read from residents in Queen's-road asking for street lamps to be erected there. It was resolved that the matter be referred to the Electric Lighting Sub-Committee for their consideration. The question of charging a reduced price of 4d. per unit for public elementary schools was considered, when it was resolved that the price remain at 5½d. as heretofore. The electrical engineer was instructed to attend in Wolverhampton to witness the testing of the balancer at the Electric Construction Co.'s works. The district auditor having disallowed the expenses of the electrical engineer for attending the conference of the Incorporated Municipal Electrical Association, it was decided to make strong representations to the Local Government Board on the importance of local authorities sending delegates to such conferences.

Digitized by Google

Llandrindod Electric Light Co. — Mr. Justice Lawrence has extended the time during which the registration of certain debentures may take place, the delay in registration having occurred through inadvertence.

"Ebonestos."—Messrs. B. Weaver and Co. advise us that on and after Sept. 1, 1905, this firm will trade as "the Ebonestos Manufacturing Co.," 22, Rosoman-street, London, E.C. The personnel of the firm will not in any way be altered.

New Offices.—Messrs. Balcke and Co., specialists in water cooling plant, of 27, Clement's-lane, London, have opened new offices at Newcastle and Glasgow, and have appointed Mr. J. E. Weyman their sole representative for the North of England and Scotland.

Swansea.—The contract for the work necessary to provide intercommunication between the municipal and National telephones at Swansea has to be completed in 11 weeks, and it is confidently expected that the long-desired intercommunication will be effected by that time.

Scunthorpe.—At the Urban District Council's meeting, plans and specifications for the electric light undertaking were approved. It was resolved to submit them to the Local Government Board for approval and apply for powers to borrow £4,500 for such purposes, the loan to be payable in 40 years.

South Shields.—The County of Durham Electrical Power Distribution Co. made an offer to the Corporation to supply current at ·45d. per unit, plus a fixed annual charge per kilowatt, and take over the Corporation's generating station and equipment at a substantial rental. The offer has been declined.

Hornsea (Yorks.).—At the meeting of the Urban District Council a letter was read from the Post Office in regard to telephone service, offering a £5 rate on 40 subscribers being obtained, and a £7. 10s. rate for a less number. The town has 3,000 inhabitants, and is in proximity to Hull. It was decided to accept the offer.

Cardiff.—Telephonic intercommunication between the two local telephone systems will be provided as soon as the necessary apparatus can be erected. As soon as intercommunication can be effected without causing delay in Cardiff district, subscribers to the Post Office and National Telephone services will receive notification.

Windsor.—At the last meeting of the Board of Guardians, the clerk reported that the plans with regard to the electric lighting scheme at Sunninghill had been received by him. A letter from a committee at Sunninghill asking for permission to erect the necessary standards for gas lamps was held over for the surveyor's report.

Eastern Telegraph Co.—The company notifies the opening of a telegraph station at Exchange-buildings, Quayside, Newcastle-on-Tyne, for the direct transmission of telegrams with all parts of Australia, New Zealand, China, Japan, Straits Settlements, Dutch Indies, Philippines, India, the Red Sea, Africa, the Mediterranean, Greece, Turkey, Spain, Portugal, and South America.

B.T.H. Lamps.—The British Thomson-Houston Co. will hereafter make no distinction in price as between their high-voltage and low-voltage incandescent lamps. Heretofore a distinction has been generally made against the high-voltage lamp in this respect, and this has not infrequently led to complaints from consumers when the supply has been changed over from low voltage to high voltage.

Bootle.—The following new scale, giving a reduction of charges has been adopted by the Corporation: For electric energy supplied for lighting, a flat rate of 3½d. for each unit used. Consumers at their own request will be charged on the demand indicator system as heretofore, at the rates of 6d. and 1½d. per unit. For power, heating, etc., 2d. for each unit to 500 units a quarter, and 1d. for each unit in excess of 500 units per quarter.

Torquay.—At the meeting of the Town Council on Tuesday, further consideration was given to the report of the Electricity Committee recommending that the generating station should be extended as advised by Mr. Waller, the consulting engineer, to provide additional energy for lighting, and also for the tramway system under construction by the Dolter Co., the total cost of the extensions being estimated at £9,500. After some discussion the report was adopted.

South African Work.—We gather from the *British South African Export Gazette* that an electric light installation for Vryheid is under consideration. The Natal Government propose to spend £36,000 on new electrical equipment (power, lighting, and cranes) for the Bluff. Owing to the wreck of the "Clan Munroe," fresh orders, it is stated, will have to be given out for the machinery for the power-house of the Johannesburg electric tramways. Electrical traction is to be installed at the Rietfontein "B" gold mine.

Chertsey.—The Rural District Council has received copies of resolutions from the Parish Councils of Windlesham and Chobham objecting to the application of Messrs. Foote and Milne for an electric lighting provisional order. The clerk also read a letter from the company, in the course of which it was stated that they had given up the idea of overhead wires running alongthe public roads, and that, if requisitioned, they would be bound to lay mains for a general supply anywhere within the area. This meets the chief objection of the two above Councils.

Mynyddislwyn.—At the monthly meeting of the Council a notice with regard to an application for statutory powers by a private company to supply electricity in the Rhymney Valley was discussed. Councillor D. Williams said that the Council had had expert opinion as to the advisability of the Council applying for a provisional order for themselves, and he thought, seeing that they had gone so far with the matter, they ought to go on with it and not allow themselves to be superseded by a company. Eventually the matter was deferred for further consideration.

Seaton.—At the last meeting of the Urban District Council, Mr. W. Purvis, engineer, of Exeter, appeared before the Council and said he intended to apply for a provisional order for the installation of electric light in Seaton. He asked the Council whether they would join in some draft agreement. The Chairman said they would take some time to consider the matter. He did not suppose they wished to say at once that they would have nothing to do with it, or that they would support the scheme. Mr. Purvis pointed out that any members of the Council who were gas shareholders could not speak or vote in the matter. It was stated that all the members of the Council were gas shareholders. This is hardly a case, however, in which silence gives consent.

Ellesmere Port.—At the monthly meeting of the Urban District Council the erection of telephone poles in the port was discussed. It was explained that the company would, as far as possible, fix no posts in the streets. In a few cases it was a necessity. In Station-road there was no difficulty. In Queen-street they must fix poles along the street, but these would be square and somewhat ornamental. Unless that privilege was granted it would be an impossibility to give the telephone service. The length of the poles would make it impossible to get them through some of the passages, and lifting them over the houses meant much expense, and sometimes damage. There were too many wires to fix them to the chimneys. It was agreed to help the company wherever possible, and permission was given to erect the poles along Queen-street.

Wembley.—At a recent special meeting of the Urban District Council it was resolved that a special committee be appointed to consider and report (1) as to the application of the North Metropolitan Electrical Power Distribution Co. and the Mutual Electricity Co. for provisional orders authorising them to supply electricity within the urban district of Wembley; (2) whether it is advisable to apply for a provisional order and work the undertaking themselves, or enter into any arrangement for the same to be taken over by a company; (3) if necessary, to inquire into and report upon the terms which either company or other companies are prepared to take over the order from the Wembley Urban District Council and provide and distribute electricity; and (4) generally, as to the proposal to provide the district with electric lighting.

French Cable Stations in Venezuela Closed.—It is reported from Caracas that, in consequence of the judgment of the Federal Court delivered on Aug. 4 confirming the dissolution of the contract with the French Cable Co., the Government ordered the company to close all its stations on the coast from the 5th inst. The cable can now be worked only between La Guayra and New York. Communication with the interior will be maintained by the National Telegraph at the rate of one bolivar a word. The decision is provisional pending the arrival of M. Bosquet, the cable administrator, who is expected on the 27th inst. M. Brun, the company's representative, has asked without avail for the postponement of the closing of the stations until M. Bosquet's arrival. He has accordingly communicated with the French Government and with the Legation here.

Shrewsbury.—At the meeting of the Town Council the Lighting Committee reported that the number of units of electric current sold in the March quarter was 118,801, an increase of 590 on the corresponding quarter of last year; and in the June quarter the sale was 61,732 units, an increase of 6,671, equal to 12·1 per cent. The alterations and extensions sanctioned by the Council, for which tenders had been accepted, were well in hand. The new boiler and the works in connection with the fixing of the covered tanks were completed, and the other work was being pushed on with all speed. The committee had for some time had under consideration the desirability of securing a larger day load, and with this object in view had considerably reduced the charge for electricity for motive power, and in this way they hoped to have a considerable increase in the number of power consumers. The report was adopted.

Hanley.—The Electric Lighting Committee learn that the Fenton Urban District Council have come to the conclusion that it would not be a profitable undertaking on their part to go to the expense of laying down mains and cables for the purpose of electricity in bulk being supplied for distribution in their district. It was decided that Mr. C. H. Yeaman be authorised to lay mains to enable electrical energy to be supplied to Cauldon-road and Wellington schools. The terms for supplying the new post office with electricity have been referred to a sub committee. At the same meeting the electrical engineer reported that he had found, upon examining some of the old solid mains, that the wood troughing had perished, and that as such material could not be expected to have a long life where laid in made-up ground, he recommended that in future mains be laid solid in earthenware troughing, and that for spare ways insulating pipes be laid when the ground is open to meet future needs.

Burslem.—The Town Council have recently completed the erection of electricity and refuse destructor works, at a cost of between £30,000 and £40,000. From these works the Corporation, under an arrangement with the Tunstall Urban District Council, propose to supply electric current for lighting power in the Tunstall district as well as in their own borough. On Tuesday afternoon the dual works were formally opened by Mr. Robert Heath, high sheriff of the county. The members of the Town Council, Tunstall District Council, Wolstanton District Council (a portion of whose area is also to be lighted from the electricity works), and a number of invited guests assembled at the town hall and proceeded to the works, which were formally declared open. Mr. Ashton Bremner, the borough electrical engineer, having given a short description of the works, the party returned to the town hall, where luncheon was served, and a number of congratulatory and complimentary speeches were made.

Wrexham.—At the last meeting of the Electricity Supply Committee the borough electrical engineer reported as follows: Total consumption in units for July, 1905, 32,556; July, 1904, 29,143. Total

Digitized by Google

number of consumers July, 1905, 186; July, 1904, 138. The following statement of cost of extension scheme was laid before the committee: Amount included in loan of £5,600 for extension of cables, being the estimated cost of the original scheme, £5,514. Cost of extension work to date: on works included in revised scheme, and on works in addition to above (Norman-road, Lord-street, etc.), £3,583. Amount raised in excess of sum expended, £1,931. Expenditure to date below revised estimate, £1,111. A sum of £814 will be available for connection of future consumers on the route of extensions. The borough electrical engineer is to ascertain the number of gas lamps between points where incandescent lamps have been placed, and report as to the cost of providing means of street lamp lighting with electricity throughout.

PROVISIONAL PATENTS, 1905

AUG. 28.

17377. Improvements in stopping tramway motor and like road vehicles. William Henry Steep and Charles Robert Everson, 4, South-street, Finsbury, London.

17380. Improvements in automatic telephone exchanges. Charles Mark Jacobs and Arthur Harold Nicholson, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

17402. Improvements in and relating to electric cells or galvanic elements and to switching devices for controlling the connections of the same. Heinrich Stern and Gustav Engisch, Thanet House, Temple Bar, London. (Complete specification.)

AUG. 29.

17433. Improvements in fittings and accessories pertaining to electrical incandescence lamps and the like. Walter Reginald Lambert, Birkbeck Bank-building, High Holborn, London. (Complete specification.)

17447. Improvements in electric meters. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

17468. Improvements in alternating-current electromotors. Albert Henry Midgley and Benjamin Reed, Norfolk House, Norfolk-street, Strand, London.

17473. Improvements relating to electric lamp holders. James Paterson, 18, Southampton-buildings, Chancery-lane, London.

17495. An improved alternating-current commutator machine. Emil Korrodi, 6, Lord-street, Liverpool.

AUG. 30.

17521. Improvements in electrically-driven grinding attachment for metal-turning lathes. Henry Humphreys, William Humphreys, and Albert Humphreys, Horsedge Electric Works, Oldham, Lancashire.

17531. Improvements in polarised electromagnets. William Drury, Prince's road, Teddington, Middlesex.

17537. Improvements in telephone spring jacks. William Aitken, care of British Insulated and Helsby Cables, Limited, Edge-lane, Liverpool.

AUG. 31.

17572. Improvements in and relating to car brakes. William Sears Washburn, Old South-building, Boston, Massachusetts, United States. (Complete specification.)

17624. Improvements in automatic signalling and train-controlling systems. Henry MacDavenport, 31, Bedford-street, Strand, London. (Date applied for under Patents Act, 1901, Sept. 8, 1904, being date of application in United States). (Complete specification.)

17643. Improvements in electrical tractors. Léon Gerard, 4, South-street, Finsbury, London.

17653. Improvements in dielectric separators. Alfred Julius Boult, 111, Hatton-garden, London. (Henry Moore Sutton, Walter Livingston Steele, and Edwin Goodwin Steele, United States.) (Complete specification.)

SEPT. 1.

17674. Accumulator. Henry Warren and Gustave Busschots, 131, St. Domingo-road, Liverpool.

17679. Improvements in connecting wires to binding posts in electric batteries. William Mills, 77, Colemore-row, Birmingham. (Complete specification.)

17699. Improvements in or relating to electromagnetic switches or other electromagnetic mechanism. Michael Bird Field and Ferranti Limited, 111, Hatton-garden, London.

17717. Improvements in refining or purifying indiarubber, guttapercha, balata, and the like. Hubert Price, 4, South street, Finsbury, London.

17720. Improvements in the electrolytic production of copper wire strip or the like. Sherard Osborn Cowper-Coles, 4, South-street, Finsbury, London.

17722. Improvements in sound transmitters. Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (Submarine Signal Company, United States.) (Complete specification.)

17731. Improvements in or relating to the means for automatically operating the points or junctions and switches of tramways for the cars or vehicles travelling thereon. Frederick William Constantine, 8, Quality-court, Chancery-lane, London.

17737. Improvements in and relating to the deposition of metals. Ivon Esser Lewis and James Albert Corey, 27, Chancery-lane, London. (Complete specification.)

17740. Apparatus for exploding mines by means of electrical waves. Ferdinand Schneider, 60, Queen Victoria-street, London. (Date applied for under Patents Act, 1901, Oct. 25, 1904, being date of application in Germany.) (Complete specification.)

17742. Improvements in artificially-cooled electrical machines. Franklin Wise Howorth, 46, Lincoln's-inn-fields, London. (The Maschinenfabrik Oerlikon, Switzerland.)

SEPT. 2.

17763. Improvements in and connected with signalling arrangements for electric tramway systems, railways, and the like. Nehemiah Norris, 5, John Dalton-street, Manchester.

17764. Improvements in fittings or appliances for use in connection with cable-suspended electric lamps. Frederick Ernest Spittle, 24, Temple row, Birmingham.

17772. An electric signal indicator for railway engines. Arthur John Hayter, 39 Heathfield South, Twickenham.

17800. Improvements in safety fuse apparatus for electrical installations. Josef Hartig, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

17803. Electric reproducing apparatus for use with phonographs, gramophones, and the like. Philip Davenport, 322, High Holborn, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Sept. 21.

1904.

11920. Manufacture of electrodes for electric accumulators. Bruno.

16760. Means for maintaining in juxta-position like poles of relatively movable magnets or magnet systems. Gercke. (Rights under Patents, etc., Act., 1901, not granted.)

18434. Apparatus for transmitting and receiving messages and the like. Donlevy.

18926. Terminal connections for electrical wires. McDermott.

19423. Internal insulation of tubes and fittings for electric conduits. Taylor.

19748. Apparatus for supplying alternating electric current. Berry.

19822. Starting resistances for electric commutator motors. Latour. (Date applied for under International Convention, Sept. 16, 1903.)

20553. Vapour electric apparatus for rectifying and other purposes. Carolan. (General Electric Company.)

20826. Seats for use in exposed situations such as the roofs of tramcars and elsewhere. Wetherell and Smith.

21144. Electric lighting of trains. Leitner and Lucas.

22511. Blowing magnet arrangement for arc light lamps. Beck.

22659. Manufacture of composition or compound for brushes of dynamo-electric machines, for bearings, and for other articles. Morgan Crucible Company, Limited, and Spiers.

22695. Mariner's compass. Thomson, Baron Kelvin, Kean, and Kelvin and James White, Limited.

22817. Electric power transmitting mechanism applicable to motor vehicles and other similar purposes. British Thomson-Houston Company, Limited, and Hoppe.

23015. Devices for automatically operating the points and switches of electric and other tramways and the like from the vehicles. Jones and Jones.

23093. Contact breakers for overhead systems of electric traction. Mitchell.

23438. Magneto electric apparatus for ignition purposes in connection with internal-combustion engines. Holden.

23835. Magnetic brakes for railway and other vehicles. Braun.

24166. Electric accumulators. Monterde.

24828. Apparatus for raising and lowering electric arc lamps. Mason.

25826. Space telegraphy. Stone. (Date applied for under International Convention, Feb. 13, 1904.)

1905.

370. Vapour electric apparatus. Krub. (Date applied for under International Convention, Jan. 9, 1904.)

1243. Clip or apparatus for the screwing up or the removal of the nut or ring used for securing the shade or reflector to electric lamp-holders. Parry.

1560. Dynamo electric machines. Serveau. (Date applied for under International Convention, Jan. 26, 1904.)

2882. Construction of double-decked tramcar and other similar vehicles. De Macedo.

3135. Carbon brush-holders for dynamo-electric machines and apparatus. Zingelmann.

5371. Methods of and apparatus for insulating electrical conductors. British Thomson-Houston Company, Limited. (General Electric Company.)

Digitized by Google

5680. Drums or reels for electric cables. St. Helens Cable Company, Limited, and Kenyon.

6469. Electromagnetic speed gear applicable mainly to automobile vehicles and boats. Soc. en Participation des Automobiles "La Magnetique." (Date applied for under International Convention, Oct. 24, 1904.)

7016. Methods of receiving and indicating electrical impulses Troy. (Date applied for under International Convention, April 8, 1904.)

7029. Electrodes for electrolysers used in the manufacture of bleaching liquors. Kother.

8931. Points or switches for electric tramways working upon the slot conduit system. Connett.

10697. Receivers for electric waves. Schäfer. (Date applied for under International Convention, May 18, 1904.)

10599. Electromagnetic ignition device for explosion engines. Roos.

10629. System or apparatus for automatically releasing electric telegraphs. Ducretet.

10828. Overhead travelling hoist or "jenny" for electric or other power, and runway for same. Peake and Crosthwaite.

11290. Telephone exchange system. Dunbar.

11673. Portable electrical measuring instrument. Bourgeois.

12284. Electric tremblers. Minoggia and Mere. (Date applied for under International Convention, June 13, 1904.)

14333. Electric furnaces. Girod.

15590. Points or switches for electric tramways working upon the slot conduit system. Connett.

15752. Self-releasing brake handles for electric tramcars and other vehicles. Belmondo.

NOTES.

Electricity and Sanitation.—In a report to the Poplar Borough Council, Dr. F. W. Alexander, the medical officer of health, suggests the manufacture of a disinfecting fluid by electrolysing sea-water or artificial salt water. The action of the electric current changes the chlorides into hypochlorites, powerful deodorants and disinfectants. Further details of the proposed equipments are given elsewhere in this issue.

New Publications.—Messrs. Harper Bros. are about to publish an addition to their list of electrical hand-books a volume entitled "Practical Electric Wiring for Lighting Installations," by C. C. Metcalfe, of the Manchester School of Technology. The book, which is fully illustrated, is written for foremen, wiremen, and students, and for those who wish to acquire a practical knowledge of wiring, jointing, and fitting for the installation of electric light. The price is 5s. net. The *Journal* of the Western Society of Engineers (Chicago) dated August contains papers on "By-Products of Coke Ovens," by W. H. Blauvelt; "Experimental Determination of Air-Gap Reluctance," by Chas. H. Smoot; "The Division Engineer in Railway Work," by W. Beahan; and "Steam-Turbines," by Prof. Storm Bull.

Underground Telegraphs.—At the meeting of the Middlesbrough Chamber of Commerce a letter was read from Lord Stanley stating that, though it was true that his predecessors and himself had contemplated an underground line from Leeds to Newcastle as a future development of the underground scheme, there was no intention at present to proceed with such an extension, as there were no funds available for the purpose. His lordship added that, so far as he was aware, telegraphic communication from Newcastle had not been entirely stopped by storm, and there had not, as alleged, been occasion to send telegrams from Newcastle to London by way of Copenhagen, except in a few instances. The secretary averred that Lord Stanley was incorrect on this latter point, so that either there must be a difference of opinion as to what constitutes a "few" instances, or one side or the other must be misinformed. If the error rests with St. Martins-le-Grand, it is to be hoped that the Chamber will continue their agitation for an improved service.

Dissociation of Ternary Electrolytes.—In the *Zeitschrift Elektrochemie* Mr. G. Kümmell contributes a reply to the criticisms of Drucker, and an abstract of his reply appears in the *Journal* of the Chemical Society. The author shows that the depression of freezing point produced by a mixture of magnesium and potassium chlorides is almost equal to the sum of the depressions of the separate salts. Hence it is probable that complex ions are not formed from these salts. The E.M.F.'s of cells consisting of two calomel electrodes, one with potassium or sodium chloride, the other with magnesium chloride solution, are shown to be 0·004 and 0·002 volt respectively when the solutions are isohydric. This confirms the view that the concentrations of the chlorine ions in these isohydric solutions are the same, the small E.M.F.'s observed being due to the different mobilities of the $Na^{\cdot}$ or $K^{\cdot}$ ions and the $MgCl^{\cdot}$ ions. Drucker's method, based on the depression of freezing point, is only exact when applied to very dilute solutions. It has also the disadvantage of giving the ionic concentrations only at the freezing point, and is, therefore, unsuitable for electrolytes the dissociation of which is much affected by temperature.

Icemaking by Electricity.—The Cataract Ice Company have installed at Niagara Falls an electrically-operated icemaking plant, a description of which appears in the *Scientific American*. The machinery installed comprises a 100-h.p. 2,200-volt Westinghouse induction motor to operate an ammonia compressor, and smaller motors for the air compressor, brine pump, and crane. The tank is divided into eight compartments, each containing four plates. One of these eight compartments is emptied daily, eight cakes of ice being taken out, each of which latter weighs about four tons, or showing a daily capacity of 32 tons. The water, which is supplied from the city mains, is filtered before passing to the freezing compartments of the tank. In the operation of the plant, the anhydrous ammonia is compressed, and thereby heated and converted to a gas. It then passes to a condenser, where it is brought into contact with cold water, thus reducing it in temperature to the temperature of the water, and conveying it back to a liquid. It is then expanded into the freezing coils, which are encased in the freezing plates. These plates being submerged in the water the ice forms on the outside, and after a period of eight days this cake of ice is complete.

Magnetic Observations.—The British Association appointed Sir W. H. Preece (chairman), Dr. R. T. Glazebrook (secretary), Prof. W. G. Adams, Captain Creak, Mr. W. L. Fox, Principal Sir Arthur Rücker, and Prof. A. Schuster to co-operate with the committee of the Falmouth Observatory in their magnetic observations. A review of the investigations was presented to Section A at the South African meeting of the association. The results of the observations during 1904 have been published in the annual report of the National Physical Laboratory, and are very satisfactory. The vertical force curves have been measured for the first time, and the results for 1903 and 1904 are given in the report. Dr. Chree has published "An Analysis of the Results of the Falmouth Magnetographs on Quiet Days during the 12 years 1891 to 1902," in the *Transactions* of the Royal Society for 1904; this contains a number of interesting results, which confirm in a remarkable manner the consequences deduced from his earlier paper dealing with the Kew curves. The committee regret to learn that the difficulty of the situation has caused great delay in the building of the new observatory at Eskdale Muir, which, they are informed, cannot be ready until the end of 1906. In view of the importance of maintaining continuity of the magnetic records, they ask for reappointment, with a grant of £50.

Telegraphic Facilities. — The Corporation of Coventry are uniting with other municipalities asking for continuous day and night telegraphic facilities, and also that a Sunday service shall be available both for the receipt and delivery of telegrams. At present telegrams can in the ordinary course only be dispatched and received in Coventry during the ordinary hours of post office business, and the only way of dispatching a telegram when the post office is closed is by calling up the postmaster or telegraphist and paying a late fee, which is not returned if the telegram cannot be dispatched in consequence of the office to which it is addressed being closed. Representations were made to the Postmaster-General, who replied that it is not usual to provide for continuous attendance at places of the size of Coventry. The Corporation are, therefore, approaching various municipalities throughout the country with a view to united action being taken to secure a continuous service in towns having, like Coventry, a population of over 50,000. It is proposed to forward a resolution to the Postmaster-General and to the local members of Parliament, and also to bring the subject before the autumn meeting of the Association of Municipal Corporations. The important part which telegraphy plays in modern life well

Digitized by Google

justifies the action of the Coventry Corporation, especially as towns like Falmouth, Queenstown, and Inverness, with populations under 50,000, are provided with such a service.

Water Electrolyzers.—Attempts to obtain hydrogen and oxygen by the electrolytic decomposition of water have usually been attended with economic and other objections. The Oerlikon Company, of Zurich, have recently devised a new apparatus for this purpose, which is stated to obviate many of the disadvantages of other forms. Cast-iron electrodes are used, and between them are located resistant diaphragms, which act as insulators. The cells are connected in series, and a 10 per cent. solution of potassium carbonate is used as the electrolyte. The gases pass through openings in the plates into two separate pipes, and, together with part of the solution, are carried into the separators, where the gas is freed from the water, which flows back into the apparatus through a common pipe. It is stated that the gas can be evolved under a pressure of 2·5m. of water, the oxygen being 97 per cent. pure and the hydrogen 99 per cent. The pressure used is about 2·7 volts per chamber, although, after the apparatus has been in use for some time, the temperature rises to its maximum, about 60deg. C., when 2·3 volts are sufficient. During operation no attention is necessary, apart from the renewal of the water. To produce three cubic metres of gas 12 kilowatt-hours are required, the exact price of the gases depending, of course, on the cost of the current used. Taking this at ½d. per kilowatt-hour, one cubic metre of the gases—*i.e.*, one-third cubic metre of oxygen and two-thirds of a cubic metre of hydrogen—will cost 2d. Economically, this appears to be little better than the results obtained from the Schuckert method, but it is claimed for the Oerlikon apparatus that it is of simple construction and needs little attention.

Scientific Education in South Africa.—In his address to the Education Section of the British Association, Prof. P. D. Hahn reviewed the early instructional efforts in Cape Colony, when the land was first occupied by the Dutch in 1652, at which time the educational system was of a very elementary character. The beginning of the second period was marked by the foundation of the South African College in 1829, supplying the demand for higher education. A number of colleges were subsequently established in various parts of the colony—at Graaff-Reinet, Somerset East, Rondebosch, Stellenbosch, Grahamstown. The third period was inaugurated by the establishment, in 1873, of the University of the Cape of Good Hope; the teaching of science as an essential part of higher education dates from then. The endowment of the Jamison Chair of Chemistry at the South African College, and the building of the chemical laboratory in connection with that institution, were soon followed by the establishment of chairs of botany, physics, geology, zoology, and engineering in this and other colleges of the colony. In 1895 the South African School of Mines, with courses in Cape Town and Kimberley, was opened, and in 1902 the Technical Institute of Johannesburg was called into existence. At present the facilities for studying science at the colleges are well advanced in South Africa; but the teaching of descriptive natural science in the elementary and high schools of the colony is far from satisfactory, notwithstanding the strenuous efforts made in this direction by the Department of Public Education. With regard to the present position of the teaching of science, it appears that the schools of the colony are now going through the same experience as the high schools in the more advanced Continental countries during the last century. In conclusion, the author gave his views as to the organisation of the teaching of the descriptive natural sciences, and of the elements of the experimental sciences in the schools and high schools of the colony.

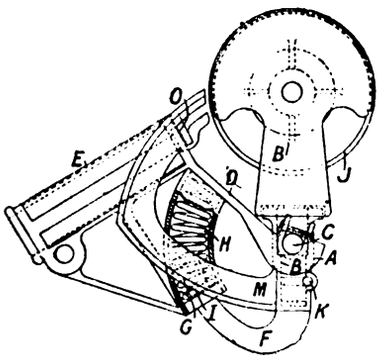
Atmospheric Electricity in South Africa.—A paper on this subject was presented to Section A of the British Association by Prof. J. C. Beattie, Mr. J. Lyle, and Mr. W. H. Logeman. The observations carried out up to now consist of a series made at Bloemfontein in 1902-1903 by Mr. Lyle, of the Grey College, Bloemfontein, and a less complete series made during the same period at Cape Town by Mr. W. H. Logeman. Observations have also been carried out in Cape Town by Mr. Fincham during the present year. The instruments used were an Elster and Geitel dissipation apparatus, and—less regularly—a Kelvin portable electrometer. The paper contains the records of daily readings of temperature, humidity, pressure, and both positive and negative leaks for morning and afternoon hours. These results are used to determine the annual variation; a harmonic analysis of the results being obtained in the usual way. Cape Town is on the coast practically at sea-level. Bloemfontein is inland, and about 4,500ft. above sea-level. The magnitude of the leak is greater at Bloemfontein than at Cape Town. The positive leak, both at Cape Town and at Bloemfontein, is less than the negative in the morning; the positive leak in the afternoon in Bloemfontein is greater than the negative in the summer months, less in the winter months. In Cape Town, so far as the observations go, it seems probable that the opposite is true, that is, from June to October the positive leak is greater than the negative, and in November and December less. Mr. Lyle and Mr. Fincham had in addition observed on several days throughout the whole day. The chief results are similar to those obtained in Europe. Formation of fog leads to a diminution in leak. The rate of leak changes with the relative humidity and with the pressure.

Institute of Mining Engineers.—The sixteenth annual general meeting of the Institute of Mining Engineers in Manchester was opened on Wednesday last, and the programme extends until to-morrow. The meetings are being held in the Lord Mayor's parlour at the town hall, where some interesting papers are being read and discussed. Amongst the five new papers presented to the meeting the first four are more or less interesting to our readers, and their titles and authors are as follows: "Leading Features of the Lancashire Coalfield Extended," by Mr. Joseph Dickinson, F.G.S; "Up-to-date Electrical Power Distribution," by Mr. Robert Loraine Gamlen; "Can Explosions in Coal Mines, with their Associated Toxic Fatalities, be Prevented," by Mr. B. H. Thwaite; "Earth in Collieries, with Special Reference to the recently issued Departmental Rules," by Mr. S. F. Walker. The second and fourth of these are referred to elsewhere in our columns. Papers which have been reproduced already in the *Transactions* of the institution are also open to discussion, and amongst these we notice the following: "The Firing of Babcock and other Boilers by Waste Heat from Coke Ovens," by Mr. T. Y. Greener; "The Electrical Driving of Winding Gears: Supplementary Note," by Mr. F. Hird; and "The Conveyor System for Filling at the Coal Face, as practised in Great Britain and America," by Messrs. W. C. Blackett and R. G. Ware. Amongst the excursions arranged for the members is one to the Lancashire Electrical Power Company's works, another to the British Westinghouse Company's works at Trafford Park, where the cable works of Messrs. W. T. Glover and Co. and the Trafford electric light and power station will also be viewed. The Manchester Corporation station at Stuart-street is to be inspected, and the

Digitized by Google

municipal school of technology will doubtless attract a large number of visitors. The meeting is, we understand, being well attended.

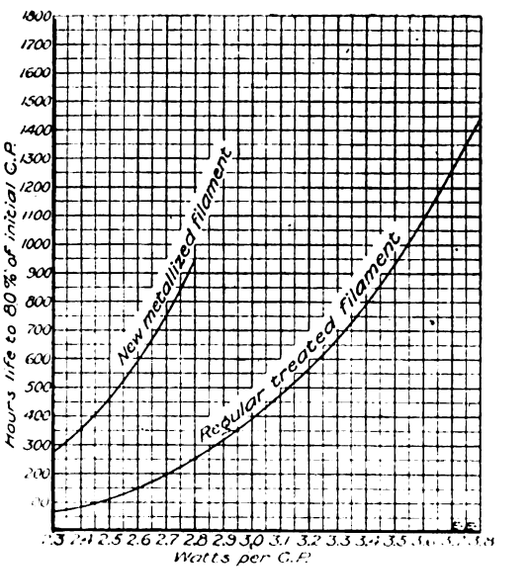
Improved Trolley Head.—We illustrate herewith a new type of trolley head for electric tramways, which was patented last year by Mr. T. Blaney, of Liverpool. Its object is to reduce the shock when the trolley wheel is passing over the suspending ears or other solid parts of the overhead system. The trolley head in question



has the socket which carries the trolley fork, B^1, pivoted at C, in a forked extension, D, of the pole socket, E, to absorb shocks due to unevenness of the wire and to reduce sparking. Two extensions of the pivoted socket are shown, one being the curved arm, F, terminating in a shoulder, I, which is in contact with a spring or an air cushion in a chamber, H, fixed to the arm D, and the other the curved arm, M, which terminates close to the periphery of the trolley wheel, J, and also carries two stops, O, normally pressed against the pole socket by the spring, H. When the wheel, J, meets a joint or any other uneven place in the wire, the wheel moves rearwardly on the axis, C, and compresses the spring, while the arm M moves with the socket and prevents the wire or any obstruction from getting between the wheel, J, and pole socket, E. The spindle, B, is grooved, and engages a pin placed in the hole, K, thus permitting the trolley wheel, fork, and spindle to revolve, but preventing them from leaving the socket A.

New South Wales.—From the report of the Commissioners for the year ended June 30 we observe that the N.S.W. Government railways and tramways both show an increase of revenue. In the case of the trams, however, there is a slight decrease in the profit, owing to an increase in the working expenses, which have advanced in rather greater ratio than the receipts. We observe that the cable system has now been entirely superseded, though a considerable mileage of steam trams still exists, and in one or two instances the horse tram is still to be found. In Sydney, which represents more than 73 out of a total of 125¾ route miles in the Colony, all the trams are electrically operated. The percentage of working expenses to revenue for Sydney, though somewhat high (83 per cent.), compares favourably with the results obtained from the other forms of traction. The precise figures for the tramways in the whole Colony were as follows for 1905 and 1904 respectively: earnings, £813,569 and £802,985; expenditure, £685,682 and £673,625—balance, £127,887 and £129,360. The electric plant at the Ultimo power-house, including an additional turbo-generator set, installed in January last, has worked satisfactorily. The total output for the year was 33,555,887 kilowatt-hours, of which the alternating-current supply was 19,110,640 kilowatt-hours, and the direct-current 14,445,247 kilowatt-hours. Of the total output, 335,080 kilowatt-hours were used for other than traction purposes. The Waverley and North Sydney sub-stations have each been equipped with an additional transforming and converting unit, while the first unit has been established at Botany sub-station, but has not yet been put into service owing to the non-completion of the high-tension feeders. A new battery-house has been erected at Five Dock, and put into service in connection with the conversion of the Abbotsford steam line to electric. The total cost of constructing the track for the 125¾ miles was £2,016.520, giving an average cost per mile of £16,036. This, however, is calculated upon route, not single-track, miles. The average total cost of the system per route mile, including all charges, works out at £28,931.

Improved Carbon Filament.—At the annual convention of the Ohio Electric Light Association Mr. F. W. Willcox contributed a paper entitled "High Efficiency High Candle-Power Incandescent Lighting Units," of which an abstract appears in the *Electrical Review* of New York. The author described an improved carbon filament for incandescent lamps, which has been developed by the General Electric Company in their laboratory at Harrison, N.J. To evolve the new filament the same process is employed as for the present type, with the addition of heating in an electric furnace at a temperature of over 3,000deg. C., this "firing," as it is termed, being employed both before and after the filament arrives at the condition in which it has hitherto been regarded as complete. It also undergoes other treatment, of which our contemporary does not give particulars. The product is an extremely pure form of carbon, having considerably less specific resistance and greater density than the present filament. The additional processes change the temperature coefficient from negative to positive. Unlike the present filament, the new type starts brilliantly and declines to normal brightness. The practical effect of these new processes is to make the filament more refractory, rendering it capable of operating at a higher efficiency. As compared with the present highest standard efficiency of incandescent lamps, an actual gain of 20 per cent. is claimed for the new type, so that it will be seen that the improved efficiency marks a very appreciable



advance. The curves in the accompanying diagram illustrate the useful life performance at various efficiencies for the new and previous filaments.

Petrol-Electric Automobiles.—One class of electrically-driven vehicle which is being experimented upon largely includes electricity only as a speed and torque varying gear between a constant-running prime mover and the axles of the car. Quite a number of the petrol-driven carriages now being experimented with for branch lines on main railways have such electrical transmission between

Digitized by Google

the engines and the driving wheels. The British Thomson-Houston Company patented recently one such arrangement for driving with an interesting controlling gear, of which the following is a brief description. In it two dynamo machines are provided, one of which always acts as a generator and the other as a motor. They are so connected electrically that both the speed and the torque can be varied. Fig. 1 shows a typical arrangement, and Fig. 2 a diagram of the connections. The armatures of the generator, G, and motor, M, are mounted on a shaft, *c*, connected to a load, C. The field magnets of the generator are driven by the gas-engine, A, and the field magnets of

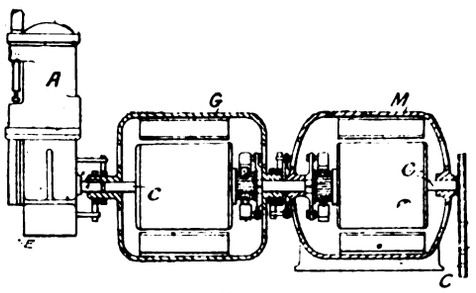


FIG. 1.

the motor, M, are fixed. The two machines are preferably electrically connected in series, and the field-magnet excitations are controlled by a controller, D, S being a reversing switch. In the position 1 one-third only of the generator field is excited, and the machines are started. In the position 3 the two machines are in series, and this position gives the slowest speed and greatest torque. In the positions 4 and 5 parts of the motor field are cut out, and the motor speeds up. In the position 6 the motor is cut out and the generator closed on itself, forming a clutch, the engine and load rotating at the same speed. In the position 7 the motor is again connected up with part of its field reversed, and the speed is thus increased beyond that of the engine. The positions 1^1, 2^1, and 3^1 are braking positions, the generator being disconnected and the motor circuit closed through the resistances, R, which in the

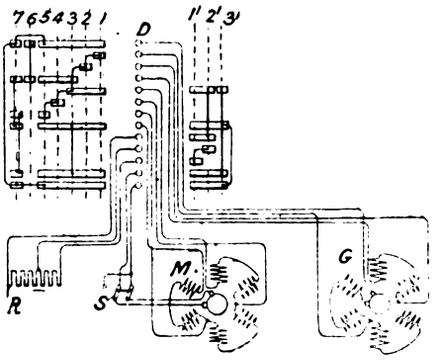

FIG. 2.

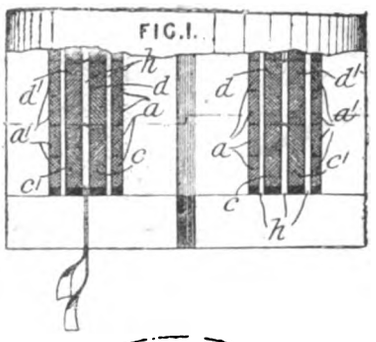
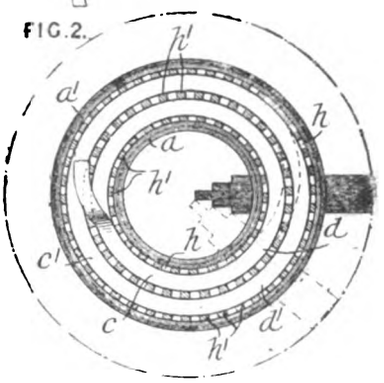
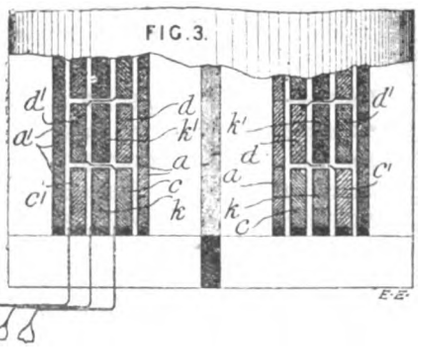
position 3^1 are cut out to give the maximum braking power. When the reversing switch, S, is thrown, the backward speeds depend upon the difference between the torques of the two machines.

High-Tension Transformer Windings.—With the increase in size of transformer units the construction of transformers has to be varied considerably from that found satisfactory in smaller sizes, in order to provide ventilating surface to carry away the heat corresponding to the energy lost in the coils and core, and also to give efficient insulation. The various devices invented by Mr. A. F. Berry to this end have been described to a certain extent in our columns. The following, however, is a description of one of his latest patented ideas for the construction and arrangement of the high-tension windings of large transformers. In the accompanying illustrations the high-tension windings, *c*, c^1, *d*, d^1, etc. (Figs. 1 and 2), consisting of insulated metal tape, preferably copper, wound flatways so that the flat surfaces of the convolutions are at right angles to the axis of the coil, and arranged in sets of concentric coils, *c*, c^1, *d*, d^1, etc, are placed between the inner and outer coils, *a*, a^1, of the low-tension winding. The inner and outer coils, *c*, c^1, of one set are connected respectively to the outer and inner coils, d^1, *d*, of the next set, and so on, the two circuits being connected in parallel or in series. In the modification shown in Fig. 3, in which there are three coils in each set, the inner and outer coils are connected as above, while the intermediate coils, *k*, k^1, etc., are connected together in series. Longitudinal ventilating passages, *h*, are left between the coils in each set, the passages being







maintained by numerous insulating strips, h^1, placed between adjacent coils. Ventilating passages may also be provided between the primary and secondary windings and between adjacent sets of coils, as shown in Fig. 3.

Incorporated Municipal Electrical Association. We have received from the secretary of this association the *Proceedings* of the Edinburgh meeting, which took place in June and July last. All the papers then read are reproduced, together with a full report of the discussions on the same. These papers will be found in our columns for the early part of July. The volume also contains the tenth annual report of the council, which shows satisfactory progress both as regards membership and the active interest which is taken in everything likely to further electrical supply. Amongst the matters contained in the report is some information repecting the testing and certification of carbon filaments in incandescent lamps. The council of the association felt that the average value of the lamps in

Digitized by Google

use was considerably lower than it ought to be, with the result that consumers are called upon to pay heavier amounts, and an unfair and unnecessary advantage is given to the competition of gas and other systems of illumination. The council therefore formed, in April last, a sub-committee, consisting of the president and Messrs. Fedden, Pearce, Snell, Taite, and Wilkinson, to investigate and report, with a view to securing uniformity of practice amongst lamp manufacturers, a more accurate and reliable grading of lamps, and the discontinuance of the use on municipal supply systems of lamps which are offered at low prices, but which do not give the amount of light marked thereon, and are wasteful of energy. The sub-committee presented its report at the May council meeting in the form of a standard specification, with recommendations for the testing and certification of lamps by electricity supply authorities. The report is divided into the following sections: (1) general instructions; (2) wattage tests; (3) tests for candle-power; (4) standard candle; (5) standard of wattage; (6) standard pressure; (7) marking of lamps; (8) method of obtaining standard candle-power; and (9) limit figures allowable. Contemporary with the presentation of the above report the council received a communication from the secretary of the Engineering Standards Committee, stating that its Sub-committee on Physical Standards was about to consider the standardisation of electric lamps, and requesting that two members of the Municipal Electrical Association council be appointed as members of the Physical Standards Sub-committee. Having in view the advantages of co-operation and the probable ultimate uniformity in the findings of both authorities, the council decided to postpone the publication of its report, and has appointed Messrs. Taite and Wilkinson as representatives of the Municipal Electrical Association on the Physical Standards Sub-committee. The council hopes to issue the standard specification at an early date, and believes that uniformity in manufacture and improvements in lamp efficiencies may be looked for as a result, and this without interfering with private trading interests in the many towns and districts concerned. The balance-sheet of the association is most satisfactory, and shows a considerable surplus on the year's working. Amongst the vexed questions which were brought up for discussion at the annual meeting was the tenure of office for members of the council. A resolution was moved that a chairman of committee when once elected should serve for three years instead of one. After considerable discussion, the whole question of the representation and election of members of the council, and also the question of the commencement of the association's year, was referred for a report to be brought up before the next convention meeting. At the end of the volume a complete list is given of all the papers which have been laid before the association since its commencement. The *Proceedings* containing these can be obtained from the secretary, Staple-inn-buildings, Holborn, at the published price of 3s. 6d. per volume.

North-East Coast Institute.—In the note in our last week's issue under this heading we reversed the rival figures of cost per kilowatt installed for private power plants. Mr. W. C. Mountain, in pointing this out to us, kindly gives us some further information as follows, which was also sent in a letter to the institute. The letter reads: "With reference to the remarks made by Mr. Snell in the discussion in which he criticises the figures which I communicated to the meeting, I shall feel that my personal reputation is at stake, and I cannot under these circumstances allow his remarks to go unanswered. The main point upon which Mr. Snell and I disagree is the cost per unit for the necessary plant in a generating station, including the buildings and foundations. In installations for factories and collieries where the purchasers are prepared to put down really reliable slow-speed horizontal engines with crankshaft generators, I don't think it is necessary to instal duplicate generators, but if duplicate machinery is required, then, assuming that 600 kw. was to be installed, I would suggest putting in three units, each 250 kw., two of which would carry the maximum load in case any accident occurred, and this would probably increase my estimate of £9,000 by, say, an additional £3,000, making a total of £12,000 for, say, 600 effective kilowatts, or at the rate of £20 per kilowatt installed, this figure being rather less than half the amount stated by Mr. Snell—viz., £45. Considering further the installation of three 250-kw. sets, I don't think Mr. Snell acts quite fairly in his remarks, because if these are read carefully it will be noted that I give the figure of £12 per unit installed, or £18 assuming that one of the units is a stand-by; this, again, is only about one-third of the cost given by Mr. Snell—viz., £45. Mr. Snell then starts to challenge my figures, and writes as if I had no knowledge of the business I am engaged upon. I can only say: (1) The figures given for the two sets of engines and dynamos of 300 kw. of the slow-speed type are actual figures extracted from a contract which my firm have in hand at the present time. The same remarks can apply to the estimate for the three high-speed sets each of 250 kw., so that there is no question of doubt whatever as to the correctness of these figures. (2) Mr. Snell then takes the estimate in pieces, and makes the statement that you cannot get three high-pressure Lancashire boilers for £1,500. As a matter of fact, in an estimate I have before me at the present time a firm quotes me £440 each, or for the three £1,320. (3) Mr. Snell then questions the item of £800 as the cost of the buildings. It may interest Mr. Snell to know that in an installation which my firm recently carried out, instead of the chimney costing £800 for three 30ft. by 8ft. 6in. Lancashire boilers, the chimney, which was 101ft. 9in. high, including all foundations and a first-class job throughout, cost £268. 6s. 8d. The three boilers with their seatings, including the boiler-house, complete covering of the three boilers, etc., cost £348. 17s. 9d. The power-house, large enough for three sets of high-speed engines, would only require to be about 50ft. long by 25ft. wide by, say, 15ft. high, cost just over £500, so that if you add these three items together you will see that the estimate that I gave of £1,000 was as nearly as possible correct, and this is for a substantially-built power station and everything of the best. I further trust that Mr. Snell will kindly withdraw what he calls my ill-considered estimates, as I am sure that no practical engineer who knows the value of machinery will for a single moment accept Mr. Snell's figures of £44 per kilowatt as a reasonable price for a power installation, either in a factory or at a colliery." We agree with Mr. Mountain that power stations have an immense future before them when they can supply current within the cost at which it can be produced in private installations. It is only right, however, that owners of works should know what is the cost of private installations, both to lay down and to work, so that they can consider the relative advantages of having a public supply or generating their own power. It is interesting in this connection to remember that Messrs. E. Scott and Mountain drive the major portion of their new new works in Gateshead by means of electrical energy obtained from the local power company. The rest of their works are driven from engines and dynamos in their own power station, so that they have at their disposal every facility for making such a comparison,

THE TRANSMISSION OF POWER BY ALTERNATING CURRENTS.

BY ALFRED STILL, M.I.E.E., A.M.I.C.E.

The question of transmission of power to a distance is becoming daily of greater importance, and the following has been written with the object of presenting in as clear and simple a manner as possible the various points to be borne in mind when considering a scheme of power transmission to a distance by means of alternating currents. The choice of system to suit any given conditions hardly forms part of our subject, except incidentally. Every case must be most carefully considered on its own merits, and without a fair working knowledge of alternating currents and of the losses which occur in their transmission it is not possible to arrive at any definite conclusions. It may be found, if the distance is not very great, that continuous currents can be used with advantage; but if the distance is considerable, involving (for the sake of economy in transmission) very high pressures, alternating currents will be found more suitable.

We shall consider in succession single-phase, two-phase, and three-phase transmission; but it may be stated that at the present time, the latter system is the most generally adopted. It would be premature to discuss at this early stage the merits and demerits of the various systems, but after each system has been independently considered, we shall be in a better position to make useful comparisons between them.

Losses in Transmission.—With high voltages, such as are necessary for the economical transmission of electric power to a distance, we have to consider, not only the losses due to the heating of the conductors by the current, but also the power lost in the dielectric forming the insulation of the cables, or, in the more usual case of overhead lines, the discharge at the surface of the conductors, and the waste of power in the air. This loss of power, which is due to discharges from the surface of the conductors, is not—in the present state of our knowledge—easy to predetermine; but it will be greater with high pressures and conductors of small diameter; it will also depend largely upon the wave form of the alternating E.M.F., and to a certain extent upon the distance between the conductors, and the frequency. It is true that exceptionally high pressures have to be applied before a visible discharge to the air takes place from the surface of the conductor—probably between 100,000 and 200,000 volts for a wire ·5in. diameter—but it does not follow that there is not an appreciable leakage taking place at very much lower pressures, especially in the case of small wires. In addition to these two causes of power dissipation, we must not overlook the leakage over insulators on a long high-tension aerial line; but the amount of current which leaks to earth, or between conductors, in this manner, is very small on a carefully-designed and well-constructed line, and it is generally permissible to neglect it. The allowable loss of power in a transmission line is a matter of the greatest importance, and it will be again referred to after we have considered the various systems and arrangements of conductors; but for the present a certain percentage loss in transmission will be assumed, apart from economical considerations.

Choice of Voltage.—Generally speaking, the higher the pressure the more economical will be the transmission, because, for a given total power, the current, and, therefore, the weight of the conductors, is reduced. But there are, obviously, many considerations which stand in the way of very high pressures being used in all cases; and each particular scheme must be examined from every possible point of view before definitely deciding upon the voltage to be adopted. In the first place, a small current at a very high pressure costs more to produce than a larger current at a proportionately lower pressure, either because the generators themselves will be more costly, or because step-up transformers will have to be used. If, however, the line losses would be very considerable with the larger currents, then it might be more economical to lay out capital in step-up transformers, extra insulation of conductors, and step-down transformers at the receiving end, and so save copper in the lines. In other words, the most suitable voltage will depend very largely upon the *distance* to which the power has to be transmitted. Indeed, Mr. C. F. Scott has suggested as a rough-and-ready rule that the pressure in thousands of volts should be taken as equal to about one-third of the total distance in miles. Thus, a pressure of 10,000 volts would be suitable for a 30-mile transmission.

It is doubtful whether this rule would be applicable to the case of very long transmissions, because the difficulties of dealing with very high pressures would be enormous. As an example: for a line 300 miles long—which is by no means an unlikely distance to be practically dealt with—the pressure, according to Mr. Scott's rule, would be 100,000 volts. This is not an impossible pressure, although 80,000 volts have not been exceeded up to the present. At the same time, it is exceedingly unlikely that, for distances over 300 miles, pressures above 100,000 volts would be found possible, even if—which is equally unlikely—they could be shown to be economical. It must not be overlooked that, although by raising the pressure we reduce the losses *in* the wires, there is an economical limit beyond which the losses *between* the wires—*i.e.*, through the air and over insulators—become of the greatest importance. It has, indeed, been found that above 50,000 volts these losses between conductors increase at a more rapid rate, and it would almost appear as if the limit of economical power transmission, at the present time, is something between 400 and 500 miles at a pressure not exceeding 60,000 to 70,000 volts.

With regard to underground cables, these are quite out of the question in connection with long-distance transmission. Their cost would be prohibitive, and, apart from this, they are unsuitable for very high pressures. It is true that so long ago as 1891 there was a short length of Siemens cable at the Frankfort Exhibition conveying current at a pressure of 20,000 volts, and there are now many lengths of cable in daily use at this pressure, and even at 25,000 volts; but it is unlikely that insulated cables will be used in the near future for pressures above 30,000 volts, not only because of their excessive cost, but also on account of the very considerable capacity effects and large dielectric losses. There will, however, always be a use for insulated cables at comparatively high pressures, in connection with transmission schemes, because of the objections to carrying the overhead conductors, at extra high pressures, through towns or populous districts.

Transmission by Single-Phase Alternating Currents.

Let us assume, in the first place, that not only the load at the distant end, but also the transmission line, are without self-induction or capacity.

If E = volts between conductors at generating end;
C = the current in amperes;
R = resistance of "load" at distant end;
r = resistance of each of the two conductors;

then the total power transmitted will be

$$W = E \times C,$$
$$= C^2 \times (R + 2r),$$

and the pressure lost in transmission will be $2r \times C$.

These relations are simple, and such as would be obtained if continuous current was being transmitted instead of alternating; but if the conductors are of comparatively large diameter there will be an inductive effect which, by causing an unequal distribution of current in the conductors, leads to the *apparent resistance*, and the loss of power, being greater with a rapidly alternating current than with one that is steady and unidirectional.

Conductor Impedance.—Imagine a straight length of cable of fairly large cross section, through which a steady continuous current is flowing. The lines of magnetic induction due to this current will not all pass through the non-conducting medium surrounding the conductor, but a certain number of them—due to the current in the central portions of the cable—will pass through the substance of the conductor itself. In other words, the magnetic flux surrounding one of the central strands of the cable will be greater than that which surrounds a strand of equal length situated near the surface. It follows that, if the circuit be now broken, the current will die away more quickly near

Digitized by Google

the surface of the conductor than at the centre; and, for the same reason, on again closing the circuit the current will spread from the surface inwards.

If, now, we imagine the conductor to be used for conveying an alternating current, it is evident that, with a sufficiently high frequency (or even with a low frequency if the conductor be of large cross-section) the current will not have time to penetrate to the interior, but will reside chiefly near the surface of the cable. This crowding of the current towards the outside portions of the conductor has the effect of apparently increasing its resistance; and it follows that, if C is the total current in the cable, and r its ohmic resistance, the power lost in watts would no longer be $C^2 r$, as would be the case if the current were a steady one, but $C^2 r'$, where r', which stands for the apparent resistance of the conductor, is greater than r, its true resistance. This effect has been very carefully investigated by Lord Kelvin and others, and it is from the data obtained from their calculations that the curve in Fig. 1 has been drawn.

It is found that, for any given apparent increase in resistance of a circular conductor due to the unequal distribution of the current, the square of the diameter must vary inversely as the frequency, and for this reason the product *area of conductor* × *frequency* has been taken for the ordinates of the curve in Fig. 1, while the ratio, k, measured

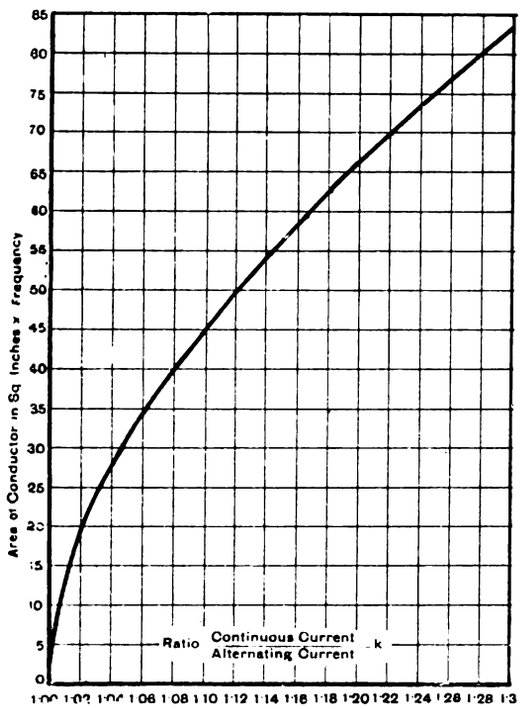

FIG. 1.

horizontally, is the number by which the true ohmic resistance has to be multiplied in order to give us the apparent resistance. As an example, consider a copper conductor ¾in. in diameter, and assume a frequency of 50. The product sectional area × frequency works out at 22·1, corresponding to a multiplier $k = 1{\cdot}025$. If, therefore, the ohmic resistance of the transmission line is r ohms per conductor, the power lost in overcoming the resistance will not be $C^2 \times 2r$, but $C^2 \times 2r'$, where $r' = r \times 1{\cdot}025$. In this example the increased loss of power with alternating current is very small, and had we taken the frequency at 30 instead of 50, which would not be exceptionally low for a power transmission scheme, the multiplier k would have been almost negligible; but with higher frequencies and large conductors the correction should always be made. The values of k obtained from the curve (Fig. 1) are correct only if the conductor is of *copper*. To obtain k for any other "non-magnetic" cylindrical conductor, the product of the sectional area and frequency must be multiplied by the ratio

$$\frac{\text{conductivity of metal of conductor}}{\text{conductivity of copper}}$$

before obtaining the corresponding value of k from the curve. If the conductor is of iron (or other "magnetic" material), the value of k may be much greater than the value read off the diagram.

It is a not uncommon belief that when aluminium conductors are used in place of copper there will be a greater increase of resistance to alternating currents than when the conductors are of copper, because of the greater diameter of wire required to give the same ohmic resistance; but the above multiplying ratio makes it clear that the percentage increase of losses with alternating currents of the same frequency will be independent of the material of the conductor (iron excepted), because the greater sectional area necessary to give the same ohmic resistance of the lines when a wire of lower conductivity is used, is evidently exactly balanced by the higher specific resistance of the metal.

Effect of Inductive Load on Line Losses.—Let us still assume the line to be without self-induction or capacity, and see what is the effect on the line losses if the "load" at the distant end has a power factor less than unity, such as would be the case if the current is supplied to induction motors. Assuming a lag of 37deg., which corresponds to a power factor (*cos* 37deg.) of about ·8, the total current to deliver the same power at the same pressure will be 1·25 times greater than if the power factor were unity, and since, for the same loss of power in the line, the resistance multiplied by the square of the current must remain constant, it follows that the cross-section of the conductors must vary inversely as the *square* of the power factor, the proper correction being made for increased *conductor*

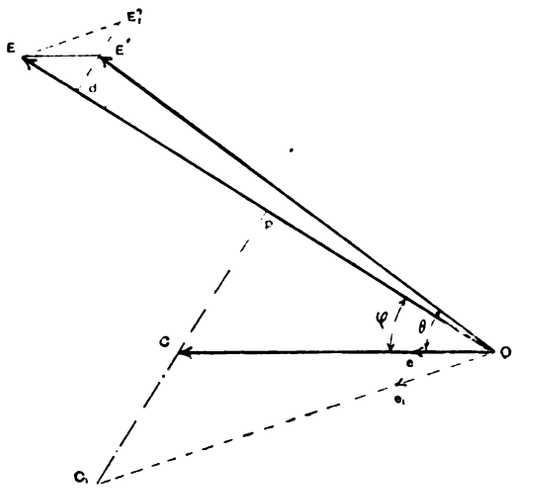

FIG. 2.

impedance if of sufficient importance. In the case under consideration the cross-section would have to be increased in the ratio of 1 to ·64, which corresponds to an increase in weight of copper of over 50 per cent. It does not follow that it would be economical to increase the section to so great an extent, but the importance of a high power factor must not be overlooked.

In the vector diagram (Fig. 2) O E′ is the voltage at receiving end, and O C the current, lagging behind E′ by an angle θ; O e is the loss of pressure in the line (equal to $2r \times C$, or to $2r' \times C$ if the correction for conductor impedance is made), and O E—obtained by compounding E′ and e—is the initial pressure at generating end. A study of this diagram leads to the conclusions (1) that the power factor at the generating end is greater than at the receiving end, and (2) that, *for a definite percentage $C^2 r$ loss in the line*, the actual difference between the pressures at the two ends of the line (represented by the distance E d) will become *less* as the load becomes more inductive—*i.e.*, as θ is increased. If, on the other hand, we let the losses in the line take care of themselves—that is to say, if we consider a line of *definite resistance receiving a definite total amount of real power at the generating end*, and examine the effect of variable power factors, we shall find (3) that for comparatively small percentage losses in the line the actual difference, E d, between the pressures at generating and receiving ends is practically constant, and independent of the power factor. The dotted lines in Fig. 2 will make this clear. Assuming the initial pressure, O E, to remain

Digitized by Google

constant, the point C of the current vector O C must lie on the perpendicular p C to the line O E whatever may be the power factor (since the *power*, $E\,C\cos\phi$, is constant): this means that the point, E′, of the vector representing the *receiving end* pressure must lie on the perpendicular d E′ to the line O E, the triangles O C p and E E′ d being similar. Moreover, since the length of the perpendicular d E′ or d E′$_1$ is small in comparison with the length O d, it differs very little from the arc of a circle described through d from the centre, O, and, therefore, the difference between O E and O E′ is practically constant under the conditions stated above.

Effect of Taking into Account the Self-Induction of the Lines. Since there must be a certain distance separating the two wires forming the go and return of the alternating-current transmission line, there must of necessity be an E M.F. of self-induction produced by the alternating magnetic flux in the space between the wires, which will be directly proportional to the amount of current in the line.

In Fig. 3, O E′ is the pressure at receiving end, and O C the current, lagging behind by an angle θ, exactly as in Fig. 2; but now, instead of merely considering the effect of the ohmic drop, O e, we must also take into account the back E M.F. due to the self-induction of the transmission lines. This E M.F. will lag behind the current by a quarter of a period, and the vector O L has been drawn 90deg. *in advance* of the current to represent the component of the total pressure at generating end necessary to balance the E.M.F. of self-induction. The

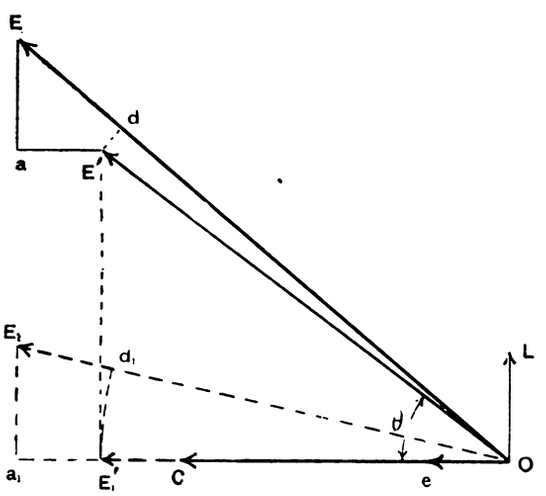

FIG. 3.

total requisite initial pressure is evidently O E, obtained by compounding the forces O E′, O e, and O L. The dotted lines show the effect of resistance drop combined with inductive drop for the same current in the line, and the same total amount of power transmitted, when the power factor at receiving end is unity—*i.e.*, when $\theta = 0$ * A study of this diagram (Fig. 3) leads to the following conclusions: (1) the additional loss of pressure due to the self-induction of the lines is of considerably greater importance on an inductive than on a non-inductive load; (2) for a given current and $C^2 r$ loss in the line, the difference in the power factors at the two ends is greatest when the load is non-inductive; (3) on a partly inductive load there is a certain value of the self-induction which, at a given frequency, will make the power factors at the two ends of the line equal—*i.e.*, it will bring O E, in Fig. 3, to coincide with O E′. If the self-induction is *greater* than this particular value, the power factor at generating end will be *less* than at receiving end, and *vice versâ*.

Predetermination of Inductive Drop.—In the diagram (Fig. 3) we have assumed the inductive pressure drop—represented by the vector O L—to be known. In order to calculate it, we must know the coefficient of self-induction of the circuit formed by the go and return wires. This will depend, not only upon the distance separating the wires, but also upon their diameters. The greater the distance between wires, and the smaller their diameter, the larger will be the amount of magnetic flux produced by the passage of unit current.

The curve drawn in Fig. 4 is plotted from figures published by Messrs. Houston and Kennelly in an article which appeared in the *Electrical World* a few years ago. It gives the coefficient of self-induction per mile of *single conductor* ·4in. diameter in millihenrys.* If the diameter of the wire is not ·4in., the coefficient of self-induction must be read off the curve, not to correspond with the actual distance, a, between the wires, but for an imaginary distance, a', such that

$$a' = a \times \frac{\cdot 4}{d},$$

where d = the actual diameter of the wire in inches.

The well-known formula for the E M F. of self-induction, *on the assumption of the wave forms being sine curves*, is

$$e = 2\,\pi\,n\,\mathrm{L\,C},$$

where n = the periodicity;
L = the coefficient of self-induction in henrys;
C = the current in amperes.

And we are now in a position to calculate the value of the vector O L in Fig. 3.

Example — Consider an overhead transmission line delivering a total power of 1,000 kw. a distance of 50 miles with a pressure of 20,000 volts at a periodicity of 25 The current (if we suppose the power factor to be unity) will be 50 amperes, and we shall assume the conductors to be

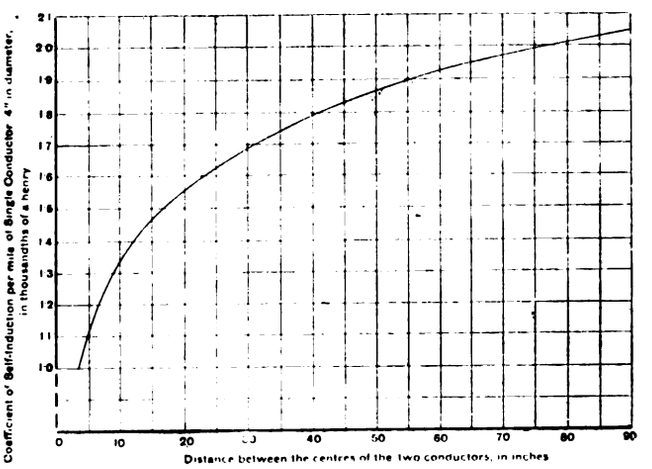

FIG. 4.

·36in. in diameter, separated by a distance of 3ft. In the first place, the correction to be made for the diameter of wire, before referring to the curve (Fig. 4), gives us

$$a' = 36 \times \frac{\cdot 4}{\cdot 36} = 40\text{in.},$$

and, taking this figure as the distance between wires, instead of the actual distance of 36in., we find the coefficient of self-induction per mile of single conductor to be 1·79 millihenrys, which makes the probable value of L for the line

$$\mathrm{L} = \frac{1{\cdot}79 \times 50 \times 2}{1{,}000} = \cdot 179 \text{ henrys},$$

and, on the assumption of the current wave being a sine curve, the expression $e = 2\,\pi\,n\,\mathrm{L\,C}$ becomes

$$e = 2 \times 3{\cdot}1416 \times 25 \times \cdot 179 \times 50 = 1{,}410 \text{ volts},$$

* This method of drawing the diagrams, which assumes the current constant and the pressure variable, to comply with the condition of constant *power* at different power factors is sometimes convenient, but the construction can readily be modified to suit the condition of a definite initial pressure.

* The calculations are based on the assumption of an even distribution of current throughout the section of the wire, such as would occur if continuous currents were transmitted, but when the applied E M.F. is a rapidly alternating one, the current does not utilise the central portions of the conductor to the same extent, and although the flux of induction *outside* the bounding surface of the conductor will be the same as before, the lines which pass through the space occupied by the material of the conductor are now fewer than in the first instance. The result is that, in the case of comparatively high frequencies, the figures obtained from the curve will lead to a calculated inductive drop somewhat *higher* than would actually be obtained. It is, however, usually unnecessary to apply any correction on this account, seeing that the wave form of the alternating current cannot be exactly predetermined, and the results of calculation are, at the best, but a more or less close approximation to the results obtained in actual working.

Digitized by Google

which gives us the length of the vector O L in Fig. 3 for the particular case considered and under the condition of full load. This is not a large percentage of the total pressure, and, moreover, the effect of this inductive drop on the pressure regulation is considerably less than if it were in phase with the supply pressure; but with large currents, high frequencies, and low power factors, the loss of volts due to the self-induction of the lines may become a very serious matter.

(To be continued.)

ALTERNATE-CURRENT ELECTROLYSIS.*

BY PROF. ERNEST WILSON, M I E E

It is well known that if an alternate current be passed between metal electrodes in an electrolyte, electrolysis may take place. For instance, it has been shown that in the case of lead plates in dilute H_2SO_4, the SO_4 combines with the lead to form $PbSO_4$, and the plates are eaten away.

The plates in a given cell were of like metal, and were separated $\frac{1}{8}$in. (·317cm.), with their opposing faces parallel. They were held in position by wooden blocks and ebonite distance pieces, bolts, and nuts. The wooden pieces covered the back of each plate, with the view of confining the current to the opposing faces. The area of each of the surfaces exposed in the electrolyte was about 150 square centimetres, but not all of each plate was submerged. For the purpose of obtaining the potential difference between the electrolyte and one of the plates, an exploring electrode, cut from the plate itself, was placed in the electrolyte midway between the plates, and by aid of a revolving contact-maker on the alternator shaft and a quadrant electrometer the curve was obtained. The distance between the exploring electrode and the plate was about 1mm. Similarly the curve of current was obtained by observing the instantaneous value of the potential difference across a non-inductive resistance placed in the circuit. The curve of current was controlled by inserting a considerable non-inductive resistance in the circuit. The E.M.F. of electrolysis is, therefore, a dependant variable as regards

The present paper gives an account of some experiments made to determine what may be the effect upon certain metals of passing alternating currents between them and certain electrolytes under given conditions. Suppose that an alternating current be passed between electrodes in an electrolyte, and that the curves of potential difference between the electrolyte and one electrode and the curve of current be observed. Let the curve of potential difference be corrected for the fall of potential due to the conductivity of the electrolyte, thereby giving the E.M.F. of electrolysis measurable in volts. Let the current curve be integrated, giving the quantity of electricity measurable in coulombs. We should expect that as the maximum coulombs per half period increased the E.M.F. of electrolysis would also increase until it had the value given by continuous current, and that with further increase of the maximum coulombs per half period, the E M F. of electrolysis would have a constant amplitude. If the process were truly reversible, we should expect to find that the E M F. of electrolysis and current would have an effective phase displacement of one quarter period in time.

wave-form. Further research should deal with variation of wave-form. Small test pieces were placed in the solution to see if any action took place without the passage of the electric current. It should be noted that during the experiment the solution in a given cell changes, and, therefore, an average result has been obtained. No special care was taken to keep the temperature of a given cell constant, and the volume of fluid in each cell was about two litres.

LEAD.

H_2SO_4 dil.—**The electrolysis produced by an alternating current when passed between lead electrodes in dilute H_2SO_4 (100 parts H_2O + 5 parts H_2SO_4 by volume) has already been studied.* It was shown that for a given R.M.S. current density over the plate, less lead per square centimetre per hour was dissolved at frequency 92·5 than at frequency 21·5. A R.M.S. density of 0·0236 ampere per square centimetre would eat away the lead in one year to a depth of 2·6cm. and 4·8cm. respectively at the above frequencies. The same current density with direct current would eat away 70cm. in a year. Since**

* Paper read before the Faraday Society, July 3, 1905.

* See the *Electrician*, April 18, 1902.

Digitized by Google

the R.M.S. current density is the same and the wave-form is the same in the two experiments, the maximum coulombs per half period will vary in the inverse ratio of the frequencies, but we do not find that the dissolved lead varies as the maximum coulombs. Referring to the table, experiments 1 and 2 show that at frequency 21·5 0·00629 grm. per hour per square centimetre were dissolved. This, multiplied by the ratio of the frequencies, would give 0·00146 grm. per hour per square centimetre, as against 0·00344 actually measured. Experiment 3 was undertaken to discover if at 92 frequency and approximately the same maximum coulombs per half period the weight of dissolved lead would be the same as in experiment 1. We find that five times as much lead is dissolved at the higher R.M.S. current density. The effect may depend upon the current density, since the maximum

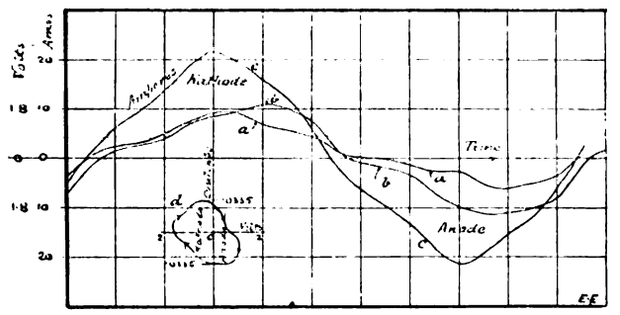

FIG. 1.

coulombs per half period are slightly less in experiment 3 than in experiment 1, whereas the current density is nearly fourfold. Also in experiment 3 the density of the electrolyte fell to 1,036 in eight hours, as against 1,049 in 15 hours in experiment 1. In experiment 3, curve *a*, Fig. 1, is the potential difference between the lead exploring electrode and one plate. This can also be taken to give the E.M.F. of electrolysis, since the conductivity drop is sufficiently small. The curve *b* is the potential difference between the plates, and *c* is the curve of current. It will be observed that the E.M.F. of electrolysis, *a*, does not change sign at the moment the plate begins to be an anode; the difference in phase represents the time taken to reverse the E.M.F. existing since the coulombs were last a maximum. The work done during this time is returned to the system. This is not the case when the plate begins to be a cathode, as the reversal of E.M.F.

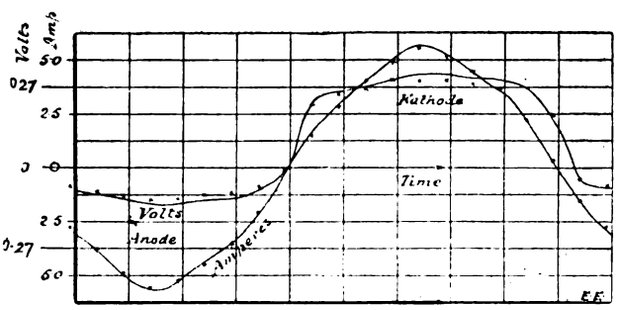

FIG. 2.

occurs simultaneously with the current. The coulombs have been plotted co-ordinately with the E.M.F. of electrolysis, giving the cyclical curve, *d*. As was previously pointed out, more work is done on the system during the time that the plate is a cathode than when it is an anode. The evolved hydrogen combines with the oxygen of the PbO_2, leading to the formation of $PbSO_4$, the maximum coulombs being sufficiently great to produce the peroxide. The plates are not, however, fully polarised in this experiment, much less so in experiment 2, and it may be that the low result in experiment 2 is attributable to the small value of the maximum coulombs. The electrolysis with lead electrodes at low current density is a subject worthy of further research. It is conceivable that electrolysis by alternating currents may be influenced by diffusion and certain local conditions. When observing the E.M.F. of electrolysis it was noticed that the electrometer deflection became unsteady at certain times of a period, indicating how easily it may be affected. In these experiments the plates were purposely placed near together, and did not give such facilities for diffusion as might otherwise have been obtained.

ZINC.

H_2SO_4 dil.—The most marked effects with zinc have been obtained when it has been amalgamated and placed in dilute H_2SO_4 (100 parts H_2O + 5 parts H_2SO_4 by volume). In experiments 4 and 5 the current densities are nearly the same, but the frequencies are different. The dissolved zinc at the higher frequency is greater than we should expect if we simply took the ratio of the maximum coulombs per half period into account. The figures are 0·00147, as against 0·00189 observed, and agree more closely than was the case in experiments 1 and 2. Again, comparing the results of experiments 4 and 6, in which the maximum

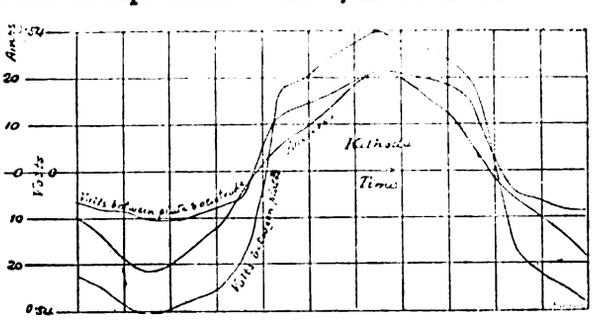

FIG. 3.

coulombs are the same, we find 0·0053 grm. per square centimetre per hour dissolved, as against 0·00695 at the higher frequency. It should here be noted that in experiment 6 the plates were not freshly amalgamated, nor was the solution freshly put up. After weighing at the close of experiment 5, the plates were again placed in the same solution and experiment 6 made. In experiment 7 freshly amalgamated plates and fresh solution were used, and the result is quite different from that obtained in experiment 6. To test the importance of the degree of amalgamation and the period of rest between amalgamation and starting the experiment, four new zinc plates were amalgamated to the same degree as nearly as possible and left nearly three days before being used. Experiments 8 and 9 were then made. Comparing experiment 9 with 7, in which the duration of test, frequency, and current density were the same, the agreement is better, since the

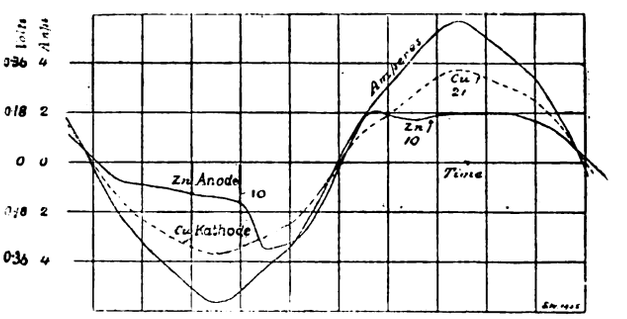

FIG. 4.

average grammes per square centimetre per hour are respectively 0·00103 and 0·00166 The results no doubt depend upon the preparation of the plates before the experiment. The full line curves in Fig. 2 were obtained during experiment 4, and the crosses show the corresponding points obtained during experiment 5. The agreement as to wave-form, phase, and amplitude of the E.M.F. of electrolysis at the two frequencies demonstrates that in the case of amalgamated zinc in dilute H_2SO_4 a change from 25 to 92 periods per second does not affect the possibility of the E.M.F. of electrolysis taking the same wave-form, amplitude, and phase relation. Experiments made with sufficiently increased frequency might throw some light upon the time taken to accomplish dissociation. Fig. 3 shows the curves obtained during experiment 7. The phase relations are practically the same, but the effect of conductivity upon the E.M.F. observed between the exploring zinc electrode and one plate when the current is near a maximum, is

Digitized by Google

slightly observable. Test pieces of amalgamated zinc were in the solutions during the experiments, and were practically unchanged in weight.

Zinc Chloride (strong).—The zinc plates in experiment 10 had, when immersed in the solution, a smooth, clean surface, and when taken out after the test they were highly oxidised. In Fig. 4, curve 10 was obtained between the zinc exploring electrode and one plate. The potential difference rises to a maximum of 0·32 volt when the plate is an anode, of which 0·01 volt may be due to conductivity. Curve 10 may be taken to be the E.M.F. of electrolysis, and it is nearly in phase with the current. Although the plates have increased in weight during the experiment, it is due to oxidation which leads to their disintegration.

Zinc Sulphate (saturated).—Experiment 11 has had little or no effect upon the zinc plates immersed in saturated zinc sulphate solution. The potential difference between the zinc exploring electrode and one plate has the same wave-form as, and is in phase with, the current. There is no visible oxidation, and the process is probably almost reversible.

Sodium Sulphate (strong).—Under the conditions of experiment 12 the zinc plates immersed in this solution have gained in weight, and are still (than before experiment) after being rubbed with wash-leather to remove the surface oxide. The potential difference between the exploring electrode and one plate is shown in Fig. 5, curve 12.

Iron.

Ferrous Sulphate (strong).—The iron plates were cut from good transformer plate and cleaned with emery paper,

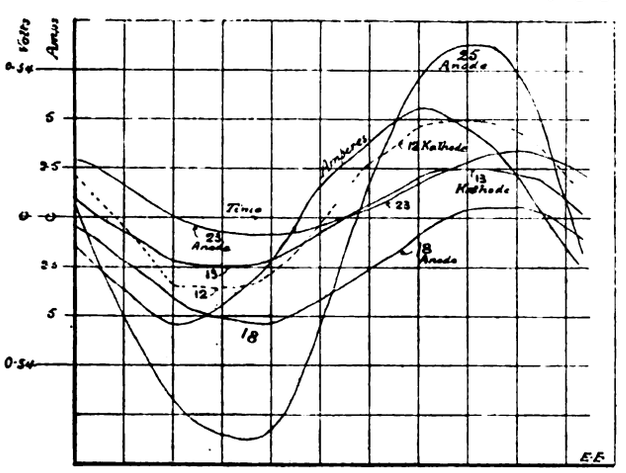

Fig. 5.

thereby presenting a bright but not perfectly smooth surface. Alternating currents have a marked effect upon iron in this solution. Experiment 13 was made first, and it was found that the plates lost 0·000462 grm. per square centimetre per hour. Without changing the solution, which during the experiment had taken up 2·4 grm. of iron, the plates, after being dried and rubbed with wash-leather to remove the surface oxide, were again inserted and experiment 14 made. The frequency was the same in each experiment, but the maximum coulombs were increased from 0·00956 to 0·0346. The result was to dissolve only 0·000457grm. per square centimetre per hour, as compared with 0·000462 in experiment 13, the solution again going up in density. Experiments 15 and 16 were then made with fresh solutions, but using tap water instead of distilled. A small quantity of H_2SO_4 was added to delay oxidation and to correct the calcium salts in the water. The result shows that 0·00389 grm. and 0·00445 grm. per square centimetre per hour were thrown down, and these are roughly eight-fold the weight thrown down in experiment 14, although the frequency and maximum coulombs are the same. The presence of some free acid in experiments 15 and 16 may be accountable for the high figues obtained. A test sample in the solution of experiment 13 lost 0·4 per cent. of its weight in 58 hours, as against 2·5 per cent. of the submerged portion in seven hours in the experiment. There is considerable electrolysis. Experiment 17 was then made. In it the solution was made with distilled water acidified to the extent of one cubic centimetre of H_2SO_4 in 2,000 cubic centimetres of water to delay oxidation, and nearly saturated with pure $FeSO_4$. Comparing experiments 13 and 17 for the relation between grammes dissolved and maximum coulombs per half period, we find that 0·000229 grm. per square centimetre per hour should be dissolved if the relation held, as against 0·000462 observed at the higher frequency. Similar results were obtained in the cases of lead and zinc in dilute H_2SO_4. Lead and iron give, roughly, the same ratio between the observed and calculated weights. It should be remembered that in these experiments not the whole of the plate is submerged in the solution, and there may be some additional effect at the surface of the liquid where it joins the plate. The curve obtained in experiment 13 between the exploring iron electrode and one plate is numbered 13 in Fig. 5. Its flat top indicates that the plates are fully polarised. It is considerably out of phase with the current.

Sodium Chloride (strong).—After washing and drying, the iron plates in experiment 18 have increased in weight, but in the solution a totally submerged test sample through which no current was passed increased weight nearly to the same percentage, so that there is no conclusive evidence of serious electrolysis. Curve 18 (Fig. 5) was obtained between the iron exploring electrode and one plate. It is very much displaced with regard to the axis of time, possibly due to the fact that the plate is easily attacked when it is an anode, thereby requiring less work during that half period. When passing from the cathode to the anode states a full quarter period in time is required before the work done on the plate becomes positive. Experiments 19 and 20 show that an increase in the weight of the plates takes place, thereby leading to disintegration.

Copper.

Copper Sulphate (strong).—In experiment 21 the copper plates acquire a fairly easily removable copper deposit, and show slightly diminished weight. The potential difference between a copper electrode, in the solution between the plates, and one plate is given in Fig. 4, curve 21. The curve is nearly in phase with the current, and has the same wave-form. One would expect a little electrolytic action. Comparing experiments 21 and 22, we see that, although the maximum coulombs are the same, more copper is dissolved at the higher frequency—*i.e.*, at the higher current density. The deposited copper in experiment 22 was not so easily removable as in experiment 21.

Sodium Chloride (strong).—In experiment 23 the copper plates were highly discoloured and covered with an easily removed metallic powder. The plates show diminished weight. In Fig. 5 curve 23 shows the potential difference between a copper exploring electrode and one plate. Comparing experiments 23 and 24, we see that much more copper has been dissolved at the low frequency than the ratio of the maximum coulombs would lead us to expect. The effect is considerable in experiment 24, and as sodium chloride is largely met with in the earth, this experiment may have practical importance. The difference would have been a little more noticeable if the detachable deposit had been removed from the surface of the plate before estimating the loss of weight.

Sodium Phosphate Na_2HPO_4 (strong).—In experiment 25 the copper plates were discoloured, but not diminished in weight. In Fig. 5 curve 25 gives the potential difference between a copper exploring electrode and one plate. Comparatively this potential difference is large. If correction were made for conductivity, the phase displacements might be sufficient to show almost complete reversibility, and thus account for the small effect observed. If this were so, the effect would be similar to what has already been observed when an alternating current is passed between platinum plates immersed in dilute H_2SO_4. Dissipation of energy still occurs owing to the decomposition of the electrolyte at the plates. Any copper phosphate formed in experiment 25 during one half period would be reduced during the next half period.

Tin.

Protochloride (strong).—In experiment 26 we see that 0·26 grm. of tin have gone into solution, thereby indicating considerable electrolytic action. The curve of potential difference between the exploring tin electrode and

Digitized by Google

one plate is not given in Fig. 4, as there was a possibility of the electrode touching one plate during the experiment. It indicated a very small amplitude as compared with the others.

ALUMINIUM.

Potash Alum (saturated).—A good deal of work has been done upon aluminium in connection with alternate currents. It is known that the film formed on the surface offers considerable resistance to the electric current. In experiment 27 two aluminium plates were immersed in a saturated potash alum solution, and owing to the formation of a surface layer the internal resistance gave rise to such dissipation of energy that the solution was boiling after the experiment had progressed three-quarters of an hour. The plates were very much eaten away in places, but quite bright where they had been protected by the surface layer.

In conclusion, I wish to express my thanks to Prof. E. F. Herroun for valuable suggestions. Mr. D. Sheppard worked with me all through, and prepared the experiments. Mr. T. Mitchell has also rendered assistance, and has worked out some of the results. To these gentlemen I tender my thanks.

INTER-RELATION OF BALLAST AND GLOWER IN THE NERNST LAMP.*

BY LEWIS A. TERVEN.

The problems presented by the glower and the ballast are very difficult taken singly, but when a problem of one

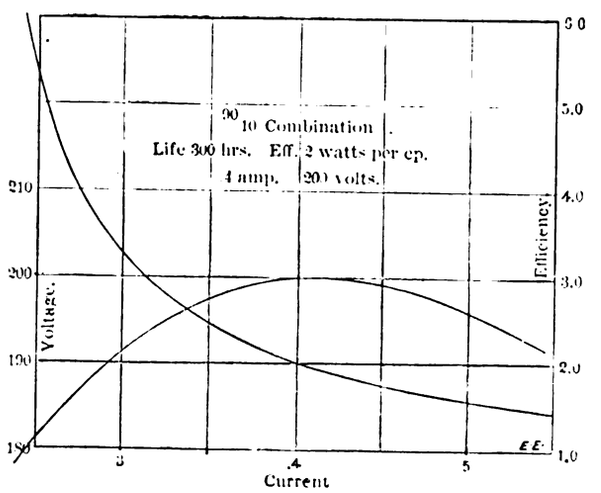

FIG. 1.—Curve on Average Glower.

is complicated by interconnection with a problem of the other the case becomes very complicated. It has been often said that the more complicated in theory an apparatus is, the simpler it operates in practice. While this is of itself untrue, at the same time the saying carries some truth. It is well known that the induction motor is an apparatus capable of a great deal more abuse than the direct-current motor, although direct-current apparatus is much simpler in design. Such is the case with the Nernst lamp. That it is a complicated lamp is freely granted, but that these complications interfere with the operation of the lamp is not admitted. The understanding of the physical occurrences of minor importance in the filament of the ordinary incandescent lamp offers just as many difficulties as do the parts of the Nernst lamp, but these small things have never been thoroughly investigated for the simple reason that there was no practical use in doing so.

Because the Nernst lamp glower is an unstable device it is necessary to use a steadying resistance in series with it, and this resistance has been called the ballast. As is commonly known, the ballast used consists of a fine iron wire, sealed into a bulb containing hydrogen. The hydrogen not only prevents the iron from oxidising, but, on the other hand, it materially affects the molecular arrangement of the iron resistance, so that the curve between current and volts is found to be much steeper in a hydrogen atmosphere than it is under other conditions.

* From the *Electrical World and Engineer* of New York.

Fig. 2 shows the normal ballast curve. It will be seen that the rise in resistance of the iron wire is quite rapid just above the point upon the curve where the lamp is normally operated. The ballast curve is usually plotted on the basis of percentage. This is the only fair way to show a ballast curve, but the current scale is extended in the curve shown, which makes the ballast curve appear flatter than it really is. The ballast is a very interesting piece of apparatus from quite a number of standpoints.

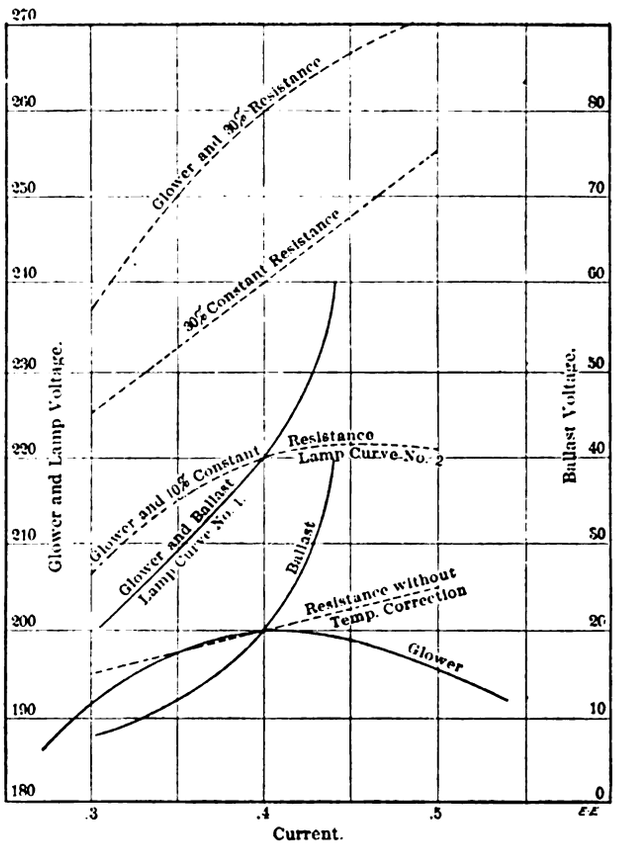

FIG. 2.—Normal Ballast Curve.

The shape of the curve may be changed and one may get a different characteristic from the lamp by working at different points upon the curve. The selection of the proper quality of the iron to be used for wire is of very great importance.

The beauty of the ballast is its sensitiveness. The reverse of sensitiveness is known as sluggishness; that is, failure of the ballast to immediately respond to changes in the line voltage. This is due to the specific heat of adjacent materials, as well as to interheating of parts and other things.

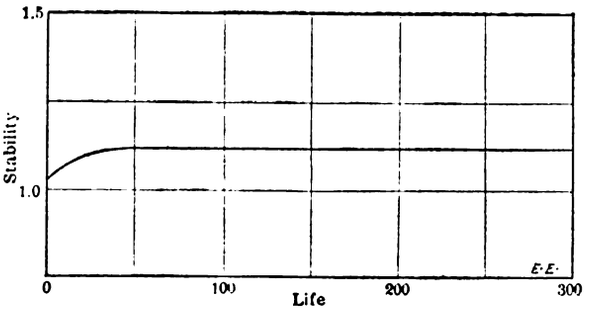

FIG. 3.—Curve showing Stability of Glowers.

The glower curve is shown in Fig. 1. This curve was taken at 300 hours, and is much steeper than the usual glower curve. In other figures, such as Fig. 4, glower curves are shown where the glower had been run only an hour. It can easily be seen by inspection that the glower changes its characteristics remarkably with age.

A very peculiar point is to be noted here. While the glower surface emission deteriorates about 13 per cent. during its life, the point upon the glower characteristic at which one operates at constant efficiency does not shift, or at least, if it does shift, moves over towards a more stable

Digitized by Google

position. This can be seen by an inspection of Fig. 3. The curve shows a very rapid rise in stability during the first 100 hours, after which the curve is flat. By stability is meant the ratio of the abscissa of the peak of the curve to the abscissa corresponding to the point of two watts per candle-power on the glower curve between current and voltage. Of course, it must be borne in mind that the glower may be operated beyond the peak of the curve, in which case the stability must be reckoned as a negative quantity.

In a previous paragraph the need of a ballast has been referred to. The necessity can be easily seen by reference to any of the later curve sheets of the paper. In Fig. 2, which shows two lamp curves taken from an aged glower, one of the curves is taken in connection with a normal ballast, while the other one is taken in connection with a straight resistance, which consumes 20 volts at ·4 ampere. Lamp curve No. 1 shows how a rise in voltage is easily taken care of by the ballast, while curve No. 2 shows a very unstable lamp, and a rise of 5 per cent. in voltage would mean the destruction of the glower. If a simple resistance is to be used as a ballast, the percentage of ballast would have to be increased from 10 to 30, in order to take care of the variation in line voltage, and even this 30 per cent. resistance does not accomplish the same

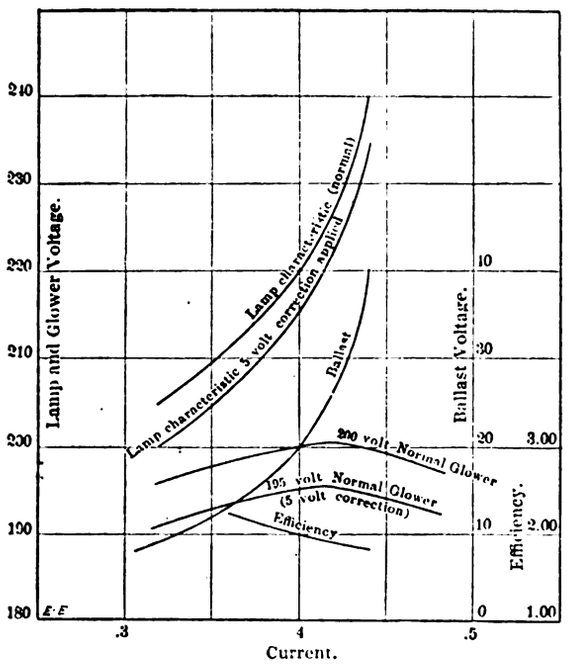

FIG. 4.—Effect of Glower Correction on Normal Glower.

result as the 10 per cent. iron ballast. One advantage of the ballast, which has no temperature coefficient, is due to the fact that the lamp is non-sluggish and the glower never gets an excess current, except that corresponding to an over-voltage circuit. The question of ballast sluggishness is a very broad one and is much too extended to be taken up in this paper.

The best way to learn how the ballast and the glower combine to make the lamp is to study curves illustrating different cases. Theoretically one has an innumerable variety of circumstances. For instance, the glower may be normal, or it may be squirted for too low or too high an efficiency. The ballast with which these three glowers are combined may be a normal, an under-voltage, or an over-voltage ballast. Taken in this way, nine curves would result, but all of these are not necessary. In Fig. 4 the normal ballast curve is combined with the normal glower curve to produce the normal lamp characteristic. The lamp curve so shown is very stable, and the lamp will withstand a 10 per cent. excess of voltage for continuous service.

The lamp will stand a temporary over-voltage of 20 per cent. without injury. On the same sheet (Fig. 4) a lamp curve is shown corresponding to a glower which is five volts lower sorted voltage than it should be. This corresponds to a method formerly used for so-called glower correction. During the early stages of the Nernst lamp development, and, in fact, up to 1903, glowers commonly had quite a rise in voltage during life. This amounts to from three to four volts per 100 hours on constant current. When such a glower is run in the lamp, during the first 100 hours it does increase in voltage by three volts, but afterward, because of running at a higher current, caused by a rise in glower voltage, the rate of rise in voltage of the glower is very small, because the rise in voltage of the glower is a direct factor of the specific consumption at which the glower is operated.

In order to partially overcome this feature, glowers after being sorted had a certain glower correction applied to them. This amounted usually to four or five volts, and was supposed to correspond to the rise in voltage of the glower during the first 300 hours—*i. e.*, a 195-volt glower would be rated as a 200—and at the end of 300 hours the voltage of the glower would really be 200 volts, which would put the lamp on its normal basis. It is seen by reference to the curve that this expedient threw the ballast into the position of an over-voltage, and the over-voltage which the lamp could stand was decreased thereby. At the same time, the glower ran at a larger current than normal, and necessarily gave more light than it was intended to give, and the efficiency was accordingly much higher than normal. Under such circumstances the decrease in candle-power of the lamp was very rapid. The custom of adding

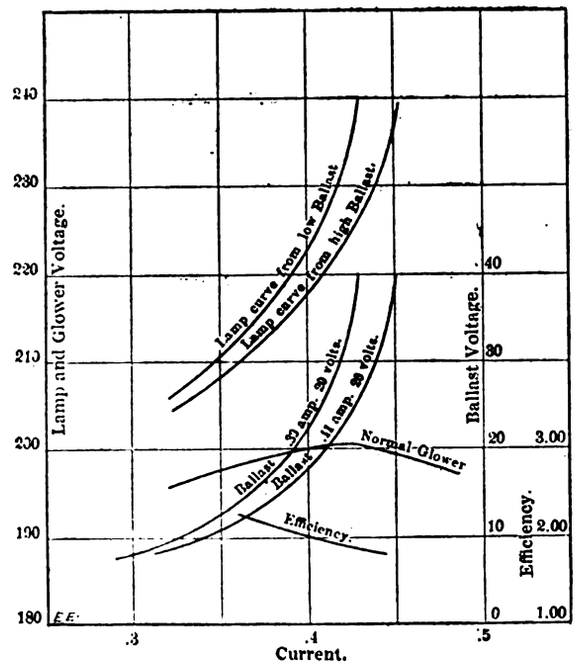

FIG. 5.—Effect of High and Low Correcting Ballast.

glower corrections was done away with in the early part of 1904, due to an arrangement being made to correct the glower mixture so as to get a material giving a very small rise in voltage with life.

Fig. 5 shows a normal glower when combined with a ballast running high in current. By referring to the efficiency curve it can be easily seen how the glower must do over duty when running with a ballast which takes an excess current, while the glower in the lamp with a small current ballast does not operate at a specific power consumption sufficiently low for a satisfactory efficiency.

A very peculiar thing may happen in case of a circuit with bad regulation, and a concrete example occurs to me which explains what I mean. Some single-glower lamps were installed upon a circuit which had a very bad regulation, rising from 104 to 117 volts, and staying at the latter figure throughout the latter part of the night. In the morning, when the light was really needed at its best, the voltage was down to about 108. Now, ordinarily, had we installed 112-volt glowers, 108 volts would have given a fairly good light, but it must be remembered that these glowers had been operated during the night on an over-voltage, and after quite a deal of service upon over-voltage necessarily rose to meet the maximum demand—that is, the glower tried to approximate the necessary voltage to take 0·4 ampere on 117 volts. Now, when burned on 108 volts one can readily see how small the current taken

Digitized by Google

will be. Such a case is not against the glower, but really shows how it accommodates itself, just as the human eye adjusts itself for the maximum light within vision.

The effect of missing the die is shown in Fig. 6. One glower has a specific consumption of 2·15 at 0·4 ampere, while the other has a consumption of 1·85 at 0·4 ampere. When compounded with a normal ballast, the glower which resulted from the large die does not get its full amount of current necessary to bring it to two watts per candle-power, as can be seen from its efficiency curve, while the glower with the small die gets more current than it should and runs at an over-consumption and strains the ballast. In Fig. 7 the worst conditions possible have been shown. Here ballast curves have been plotted where the current is too high and too low. Glower curves have been plotted where the consumption of the glower is too high and too low. By combining the ballast which runs low with the glower which runs at an under-consumption, the worst conditions are obtained for light emission. This may be seen by reference to curve No. 1. Lamp curve No. 2, which is made from the ballast curve with high amperage and the glower curve with too high consumption, is seen to be more unstable. This is because the glower runs at such a consumption as to bring it over the bend of the curve. Such a lamp will give a great deal of light, but will strain the glower. In the previous example the glower will receive no injury, but the ballast will be strained.

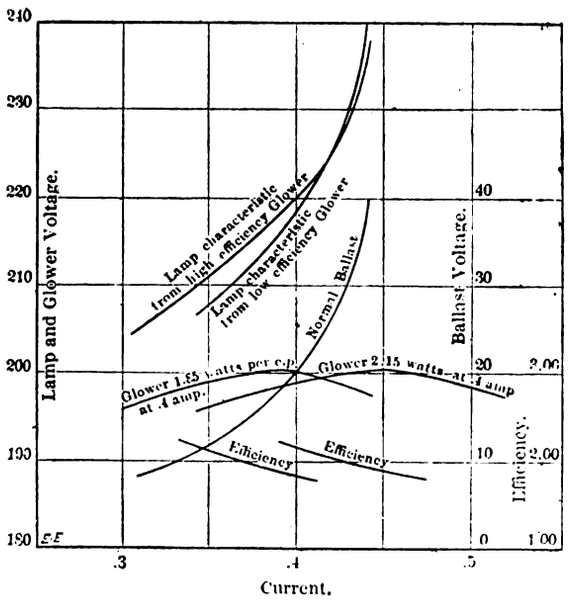

FIG. 6.—Effect of Combining with a Normal Ballast a Glower which has missed the Die.

For easy reference there is compiled a table of strains. A strain is always referred to the normal lamp, which consists of a normal glower in series with a normal ballast. When either the glower or the ballast in a lamp is abnormal, it is presumed that the parts suffer as the standard product would under conditions which produce a similar strain. For instance, if a ballast which runs 0·39 ampere at 20 volts is put into a lamp and the lamp current is found to be 0·395, the ballast is in a condition of strain, because its normal is 0·39 ampere instead of 0·4 ampere, as in the case of the regular product.

The check of any strain when referred to a similar strain upon the normal lamp is that the condition of the glower or ballast considered shall be physically the same; thus glowers are compared on the basis of equal efficiency (specific consumption) and ballasts on the basis of temperature of the iron resistance wire.

Numerical examples will illustrate the methods described. Take the case of the lower consumption glower and low ballast shown in Fig. 7. A lamp composed of these parts would take 0·397 ampere at 220 volts. The normal for the glower is 0·43 ampere—that is, at this amperage the glower runs at two watts per candle-power. Hence the glower is running at a current 0·033 ampere less than its normal. When compared to the normal lamp we find that a current of 0·368 of an ampere is required to produce similar conditions, so far as the glower is concerned, when

$$\frac{\cdot 397}{\cdot 43} = \frac{x}{\cdot 400}, \text{ or } x = \cdot 368 \text{ ampere.}$$

Referring this amperage (0·368) to the standard curve of Fig. 4, it is found that 212·8 volts is the lamp voltage which will produce 0·368 ampere in a normal 220-volt lamp.

For the ballast we have the current as above at 220 volts upon the abnormal lamp, equal to 0·397 ampere. Now, the ballast normal is 0·39 ampere, and equating as above

$$\frac{\cdot 397}{\cdot 39} = \frac{x}{\cdot 4}, \text{ or } x = \cdot 407 \text{ ampere.}$$

In other words, a current of 0·407 ampere flowing through a normal ballast produces a strain upon it which is equivalent to the strain produced upon a 0·39-ampere ballast when 0·397 ampere flows through it. Comparing this value with those found from the curves of Fig. 4, it is seen that 221·9 volts upon a normal lamp will produce 0·407 ampere.

The table of strains shows several things that could not be well obtained by a glance at the curves. Above all, it shows the great care that must be exercised in the manufacture of the glower and ballast that they will not vary in their relations to each other.

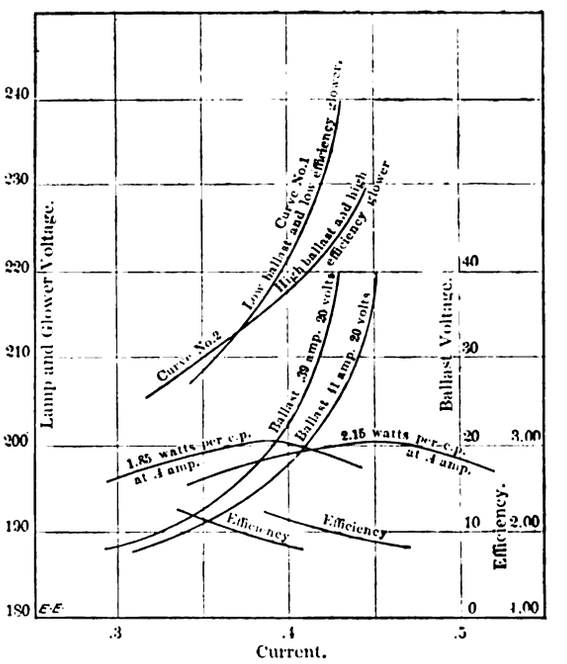

FIG. 7.—Effect of Combining a Glower which has missed the Die, with High and Low Correcting Ballasts.

TABLE OF STRAINS.

	Equivalent circuit voltage on glower.	Equivalent circuit voltage on ballast.
Five volts correction on normal glower	224·8	224·8
Low ballast with normal glower	217·5	220·4
High ballast with normal glower	222·5	219·6
Low-consumption glower and normal ballast	214·2	221·0
High-consumption glower and normal ballast	232·0	219·0
Low-consumption glower and low ballast	212·8	221·9
High-consumption glower and high ballast	240·0 plus probably 245.	220·0

The fact has been mentioned before that the glower characteristic can be materially changed by altering the proportions of chemicals used in manufacture. One certain mixture is adhered to because it is found that this mixture gives the best all-round working results, but the standard mixture is not quite so stable as a glower mixture differing only by a small percentage in its components. The curve may also be slightly changed by altering the physical characteristics of the chemicals used, without varying the proportions. It is an important matter to get as steep a characteristic as possible, and one which does not reach the knee of the curve between volts and current until a very good efficiency has been attained. However, it does not seem possible to do much better than is now being done.

When a glower is first run a great deal more light is emitted from its surface in proportion to the tem-

Digitized by Google

perature at which it is operated than happens afterward in its life. This is explained by the fact that the glower surface initially has a selective radiation—that is, the radiation is concentrated in the visible spectrum. It is not certain that the glower has a selective radiation. The phenomenon is possibly caused by the fact that the glower has a certain porosity when new, but with age it attains a crystalline structure. The quality of the light does vary with the surface. When the glower is new the light is of a whiter hue. As the glower obeys the common law for black bodies heated to incandescence, although it is a white body, the hue of the light depends upon a function of the absolute temperature of the glower. The quality of the light may also be shifted toward the blue end of the spectrum by absorbing rays that fall within the red and orange part of the spectrum. The light falling upon a surface after being transmitted through a thin cobalt glass wall will appear very white, even though the glower may be operating at a specific power consumption as high as 2½ watts per candle-power.

Because daylight differs so much owing to different amounts of diffusion which it has undergone, it would be difficult to give a table showing how near the Nernst glower approaches daylight for different efficiencies. If a glower is exposed to the sun on a bright day, and it is attempted to make the light of the glower falling on a white screen equal in value to the light falling direct from the sun, it will be found that the glower must be operated at as low a consumption as 1·2 watts per candle-power. Under such circumstances a glower will not live very long. On the other hand, if one wishes to duplicate diffused daylight in a hall it can be easily done with glowers running at two watts per candle-power, but it must be remembered that if shades are put upon the glowers the tendency is to throw the spectrum down toward the red end. The diffused light in ordinary residences is duplicated almost exactly by the light received from Nernst lamps using opalescent balls absorbing about 16 per cent. of the light passing through them. Heavier balls usually give a yellowish effect to the light. Sand-ballasted and etched balls do not play so much havoc with the colour value of the light.

In what precedes is given a study of the ballast and the glower under circumstances where a sufficient time has elapsed after starting the lamp that the operation of the lamp will have attained its final value. Everything is much more complicated during the time the lamp is starting and up to 30 minutes after the switch is turned.

UP-TO-DATE ELECTRICAL POWER DISTRIBUTION.

BY ROBERT LORAINE GAMLEN.

A paper on the above subject was communicated on Wednesday last to the meeting of the Institution of Mining Engineers in Manchester. In the first part of this the author gives an interesting *résumé* of electrical progress during the past 28 years, confining his attention more particularly to the growth of the distribution of electrical energy. The transmission of current to London from the Deptford station at 10,000 volts in 1885 is referred to as the pioneer to long-distance power transmission. The introduction of the three-phase system for transmission and the three-wire system for distribution are also alluded to by the author. He also shows that electric lighting engineers have appreciated the value of a power load as a means of increasing the hours during which their plant can be usefully employed. In this respect, however, the large power companies have the advantage that their works are designed after experience gained from the smaller stations of electric supply undertakings. Thus he shows that in the records of electricity concerns a capital of £100 per kilowatt of plant is no uncommon figure, but a quarter of this figure should be obtained by a power company. The capital of an electric supply company is spent on lands, buildings, boilers, engines, dynamos, auxiliary machinery, switchboards, mains, sub-stations, and distributing apparatus. The factors controlling the choice are absolute immunity from breakdown, perfect regulation, small fuel consumption, ease of working, and consequently a low wages bill. The balancing of these factors so as to obtain the best economic results is the art of designing the power system.

Mr. Gamlen then describes what has been done by the Lancashire Power Company in their new station now completed. Before doing so, however, he refers to one point which has been discussed a good deal lately with reference to power generation, and it would be as well to dispose of it now. The question is that of generation of power by means of gas-engines, the only excuse for the gas-engine being diminished coal bills. The cost at which power can now be produced by large turbines is so low that the diminution which could be obtained by using gas is of less importance than it was some years ago. A really large saving can only be obtained by using ammonia recovery, and such processes are hardly desirable adjuncts to high-pressure power stations. The arguments against the utilisation of the gas-engine are chiefly constructional ones: the floor space required for a 2,000-h.p. two-cycle gas-engine, without any auxiliary apparatus, is about 2,800 square feet; a Curtis turbine of the same capacity need only have 120 square feet. But 2,000 h.p. for a power company is a smallish set, 8,000 h.p. being more near to the useful standard size. No gas-engine of such size has yet been constructed, and if it were it would be a horrible enormity. The time may come when the long-dreamed-of gas-turbine will become an accomplished fact. This will, of course, greatly change matters, and then steam may find a serious rival in the internal-combustion engine. Another objection to the gas-engine is that the angular velocity is not sufficiently constant, and upon perfectly even turning a great deal of the utility of the modern power company, especially in Lancashire, depends. The turbine has an absolutely constant angular velocity. A turbine drives a three-phase generator with even running, the speed of the three-phase motor bears an exactly constant ratio to that of the generator, and consequently the machine, driven by a motor in this way, will also have a perfectly constant speed. Further, experience has not yet demonstrated the reliability of gas-engines of above 500 h.p. or 600 h.p., and it is essential that a power company shall be reliable above all other things.

The power companies have in nearly all cases laid out their schemes on somewhat similar lines. Three-phase distribution has been adopted at a pressure generally of about 10,000 volts. The current has been generated at high pressure, generally by means of turbines running with high vacuum and high superheat. The water-tube boiler has been universally adopted and one or another form of mechanical stoker used.

In the case of Lancashire, the first station has been placed between the River Irwell and the railway, upon the far side of which is a coal mine, from which supplies can be obtained. The site is convenient, inasmuch as there is an ample water supply for condensing purposes; the railway being situated above the boiler-house, the coal is conveyed by gravity into the bunkers, and thence it is fed on to chain-grate stokers operated by electric motors. The first boiler-house is divided into two banks of three boilers. The two banks are each capable of evaporating 60,000lb. of water per hour. The boilers feed on to one common ring of pipes, and the turbines are fed from the same, so that two turbines are fed from one bank. One bank of boilers, then, with its chimney and two turbines, constitute one unit. It is proposed to make extensions in like manner, except that, instead of one bank of boilers feeding two turbines, each bank will feed one machine of larger capacity. The water-tube boiler is used on account of the very great steaming capacity for a given floor space, and for its great powers of responding to forcing. It is, of course, highly important when dealing with large-size generators to arrange that sufficient boiler capacity can be available without the steam having to travel through vast lengths of main. By placing the boilers at right angles to the turbines, very satisfactory arrangements can be arrived at.

The turbines revolving at 1,000 r.p.m. look, of course, exceedingly small for the amount of work they do; indeed, the amount of power that can be obtained on a certain floor space by their means seems nearly incredible to the engineer who has been accustomed to work with the older slow-speed engines. The turbine lends itself particularly

Digitized by Google

well for condensing; in the case of the Curtis turbine there is no exhaust pipe, the condenser being coupled direct to the engine. This can be done in two ways, either by placing the condenser side by side with the turbine, or underneath, either arrangement being very compact and convenient. In Lancashire the air-pump is placed beyond the condenser, so that the three form really one plant. The result is that an engine-room only 96ft. long and 32ft. wide is needed to house four sets of 2,000 kw. each, or 8,000 kw. in all, whereas in nearly all previous cases as large a building has been necessary for an engine of 800 h.p. and less. When the extensions take place, this ratio of plant and buildings will diminish again, as the diameter of the 5,000-kw. set is comparatively little larger than the 2,000-kw. plant. In the case of the Curtis combination, the dynamo is placed on the same spindle as the driving buckets and vertically above them. Owing to the high speed of rotation the electrical generator is of very small proportions, the diameter being only some 7ft.; whereas an ordinary direct-coupled set, at about 150 r.p.m, would be somewhere about 25ft. to 30ft. high, and, of course, much more expensive.

Mr. Gamlen then deals with the switchboard construction, which is of the British Thomson-Houston Company's type, with remote control for all the main switches. He also shows the advantage of having high voltage for transmission, as this enables the supply to be given economically over large areas, thus securing a great variety of load on the station. It is likely, therefore, that the number of units produced by a power company when attaining to moderate size for each kilowatt demanded should reach 2½ times that of the ordinary town supply—that is, the load factor of an ordinary combined lighting and power supply will be high at 18 per cent, that of the power company should reach 45 per cent.—and this, as before explained, greatly reduces all the annual capital charges.

There is great prejudice in this country against the use of overhead mains, but this is gradually being overcome, and already great advances are being made. In the original scheme, the whole of the Lancashire mains were intended to run underground; already it has been arranged that some 10 miles of route shall be overhead. By this means expensive insulation is saved, and also the excavation and reinstatement of the roads, greatly reducing the cost of the transmission system. Further reduction is obtained also, as often the cross-country overhead route is much shorter than if the roads had to be followed. The main routes are laid in duplicate, and are planned to go through the most likely districts for supply.

Arrangements are made with the various local authorities for the supply in their areas. In some cases the current is sold to the authorities and they distribute to the small consumers at low pressure, and in other cases the company act more or less as agents for them, and look after the distribution. In all cases large power users are served direct from the high-tension mains. In most cases the current used is three-phase, as this is most suitable for almost all purposes; the reduction apparatus in this case has no moving parts and requires no attendance, so that even in this extra stage to that needed by the ordinary supply concern no extra expense is incurred.

The following points show out the general scheme of the lay-outs of the power company, and show where the difference occurs between it and the ordinary town supply: (1) the power company chooses its site near the fuel and by the water; (2) the power company spreads out over a large area and caters for a large long-hour load, consequently it can start on large lines with large units of plant, the capital cost of plant per horse-power diminishing as the size increases; (3) the load factor of the power company should reach 45 per cent.; and (4) all the working expenses of the power company per unit are extremely small on account of the size and convenience of the units. On the other hand: (1) the town supply is located by the area of supply, and it seldom can be placed near water, and hardly ever near a coal pit; (2) the town supply has a constricted area and can only work in small units, and small units are more costly per horse-power than large ones; (3) a good mixed town supply can hardly ever have a better load factor than 18 per cent.; and (4) the wages bill of a town supply is generally a large factor of the total costs.

The preceding recited points show that power companies hope to be able to supply electricity far more cheaply than town undertakings, and the future will show whether their ideas are based on fact or fiction.

ELECTROLYSED SALT WATER FOR DISINFECTING PURPOSES.

Mr. W. F. Alexander, the medical officer of health for the metropolitan borough of Poplar, has presented a report to his committee upon the manufacture of electrolysed salt water for disinfecting purposes. He shows in his report that this disinfectant can be economically obtained, and that it would be quite as effective as the disinfectants now issued by his department. The following extracts from his report will revive interest in a process which was introduced into this country some 10 or 12 years ago for the treatment of sewage by means of electrolysed salt water. This was the Hermite process, the use of which has not been extended beyond the few places where it was first tried. It is quite likely, however, that as a disinfectant for private use or for flushing drains that the electrolysed salt water may be more economical than the disinfectants now used. The production of the same would provide a steady and valuable load for the local electric supply station, as the process could be carried out in such a way as not to clash with the lighting peak. This would enable a very cheap supply of electricity to be given. We omit a considerable portion of Mr. Alexander's report which deals with the chemistry of the process, as this will be well known to the majority of our readers. To put it briefly, the electricity passing through the salt water converts the magnesium and sodium chlorides into hypochlorites. We are more concerned with the figures of cost, and on this point a good deal of recent information is given. Mr. Alexander in his report states: "I have been in communication with a firm of electrical and mechanical engineers, Messrs. Geipel and Lange, of Vulcan Works, 72A, St. Thomas-street, S.E, the successors to Messrs. Paterson and Cooper, the firm which installed the plant (Hermite system) at Ipswich, Lytham, and the Victoria Hospital, Netley. These engineers, at my request, have been in communication with friends in Paris, and finally write me as follows: 'This is as small an apparatus as we could make, and is capable of producing 250 litres of disinfectant solution per hour, having a strength of 1 grm. of chlorine per litre. Such a solution is strong enough for deodorising sewage and other like purposes, but we are of opinion that for ordinary cases of domestic sanitation a solution of half this strength would be sufficient, so that it would be possible by watering down to obtain from this apparatus 500 litres of solution having a strength of ½ grm. of chlorine per litre. We believe that with this apparatus and with solution of this strength you could have excellent results. This electrolyser would require 30 amperes continuous current at a pressure of 110 volts, but, if more suitable to you, 20 amperes would be sufficient for longer periods, or, if necessary, 40 amperes could be put into the apparatus. It would be necessary to have a rheostat in the circuit to regulate the current; the only other apparatus would be a tank or reservoir placed at a higher level to the electrolyser containing the solution to be electrolysed, which reservoir should be connected to the electrolyser by a rubber pipe. Our price for this electrolyser complete, but without the tank above referred to, would be £95, carriage from Paris extra. The solution to be employed with this apparatus should be composed of water, 1,000 litres; ordinary salt, 40 kilos; chloride of magnesium, 10 kilos.'"

As regards the cost of electricity, Mr. Bowden, borough electrical engineer, has written to Mr. Alexander that "the pressure on the ordinary low-tension mains is 230 or 460 volts. To give you a special service at an E.M.F. of 110 volts would necessitate the installation of a motor-generator, or a large resistance which would be very wasteful, unless the machinery which you propose to drive would be in duplicate, when you could run two in series,

Digitized by Google

and thus overcome the loss in the conversion from 230 or 460 to 110 volts. With reference to the cost, the lowest price that I think we could at the minute quote you for this small amount would be a flat rate of 1½d. per unit, and taking your own figures—*viz*, 30 amperes at 230 volts—this would represent somewhere about five to six units per hour, equal to 9d. per hour."

The author has also been in communication with another firm for the supply of plant for making the electrolysed solution, and understands that both firms would be prepared to supply the necessary equipment on rental or royalty. He points out that it would be more economical to instal a motor-generator to reduce the voltage than to employ a rheostat, which would involve waste of practically half the energy used. As regards the cost of manufacturing, the report reads as follows: "Mr. Bowden quotes 9d. per hour for 30 amperes at 230 volts, and, therefore, for eight hours, an ordinary day's work, the cost for electricity would be 6s. This with a rheostat, but it would be cheaper with a motor-generator, as 110 volts for one apparatus is required, but without a rheostat or motor-generator two plants can be worked in series for this sum. With a pressure of 110 volts and 30 amperes continuous current, 250 litres can be made, or 440 pints or 55 gallons per hour, the cost of the electricity, even with the waste in the rheostat, should there be no motor-generator, being 9d. In a working day of eight hours, therefore, 2,000 litres can be made, or 3,520 pints or 440 gallons, at a cost of 6s. for electricity. Rock salt costs £2 per ton; chloride of magnesium £4. 10s. For every 55 gallons of fluid there would be required 22½lb. of salt and 5½lb. of chloride of magnesium, and at the price quoted above for 440 gallons of fluid the cost would be 3s. 3d. for salt and 1s. 10d. for chloride of magnesium, and with 6s. for electricity, the total cost of 440 gallons would be 11s. 1d., against £15 for a like amount of our present fluid."

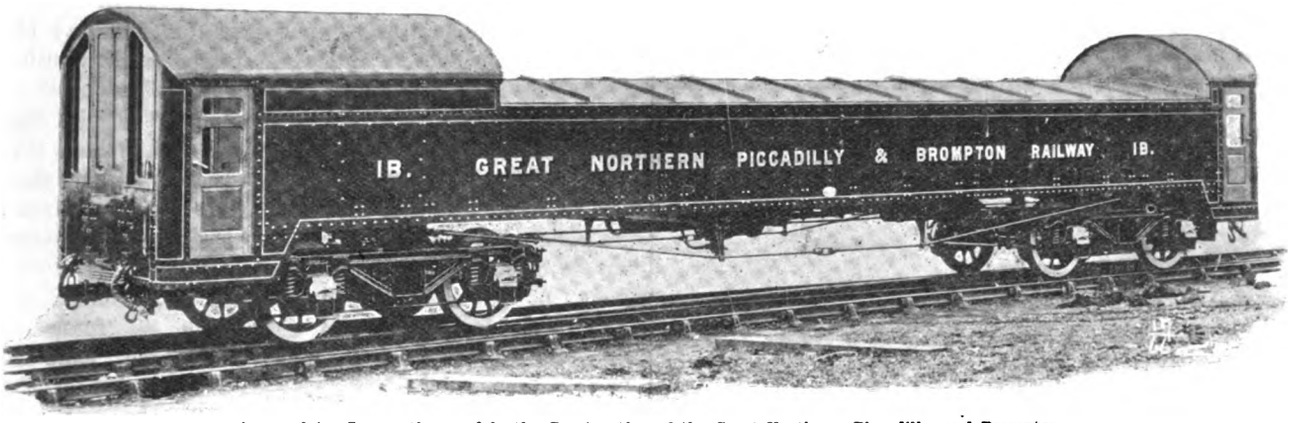
Our readers are hardly concerned with the details of the disinfectants actually issued last year by the Poplar health department, but the total cost of the same was practically £458, exclusive of labour, which cost £292 more. It will be seen, therefore, that on this expenditure there is room for considerable economies, and that it is worth while going to a reasonable capital expenditure.

In conclusion, the author states that in his opinion the health of the district must be materially enhanced by the use of electrolysed salt water as a disinfectant, and a great saving of money will be assured to the ratepayers.

We understand that if the proposal is adopted, the strength of the solution actually delivered to the public would be one containing 4 grm. of chlorine per litre. It is likely, also, that two electrolysers would be used in series, so as to avoid the first cost of the motor-generator or the energy which would be wasted in a rheostat. The first cost of the motor-generator in question would be £72, while the second electrolyser would only cost £95. It will be interesting to see the outcome of this report, and we trust that the proposed system will be given a good trial in Poplar. Success there should lead to its adoption elsewhere in the country.

ACCUMULATOR LOCOMOTIVES.

For the purpose of removing excavated material and taking in the iron tunnel segments, sleepers, rails, and other material required in the construction of the Great Northern, Piccadilly, and Brompton "Tube" Railway, there have recently been constructed by Messrs. Hurst, Nelson, and Co., Limited, of Motherwell, N.B., two electric locomotives to be worked by storage batteries, and also eight bogie wagons for use in conjunction with the electric locomotives. The locomotive bodies are 50ft. 6in. in length over buffers, and are constructed of steel, with a flooring of jarrah wood. The floor frames are of 9in. by 3½in. by ½in. channel steel, the side sills being of 8in. by 4in. by ½in. steel girders, intermediate sills of 7⅞in. by 3in. by ⅜in. channel steel, the whole trussed by two side truss rods placed under each side sill, and H steel girder needle beams carried across at each truss post. The side frames are of steel plate ¼in. thick riveted to the side sills at the bottom and to a steel angle and flat at the top, and, where the storage battery is located, are lined with jarrah wood. A view of one of the locomotives is given herewith. The batteries, which have been supplied by the Chloride Electrical Storage Company, consist of 80 Chloride cells, each containing 21 plates, and weighing in all about 36 tons. The normal discharge current is 179 amperes, whilst the maximum emergency load is 800 amperes. The batteries will be capable of storing sufficient energy to operate for a whole working day without recharging.



Accumulator Locomotive used in the Construction of the Great Northern, Piccadilly, and Brompton Tube Railway.

At each end of the locomotive there is a driver's cab fitted with a British Thomson-Houston master controller, whilst one cab (10ft. 10in. in length) is extended so as to accommodate the controlling apparatus, the air-compressor, and the air-receiver. The cabs are constructed entirely of steel, and are so arranged that they join the portion carrying the battery, the latter being on the jarrah wood floor in two divisions, separated by a lattice girder frame passing longitudinally down the car from cab to cab, and its top supporting a series of sloping doors which cover and protect the secondary batteries. The width of the locomotive is 8ft., whilst the height from rail level to top of cabs is 9ft. 6in, the distance from rail level to top of battery tank being 6ft. 8in.

The locomotives weigh 65 tons each, and their free running speed on the level, when hauling a load of about 60 tons, is from 7 to 10 miles per hour. They are each fitted with the automatic centre coupler buffers, and also with the Westinghouse air-brake.

APPOINTMENTS VACANT.

Junior Engineer, Erith Urban District Council electricity works. Applications by Sept. 18. See advertisement.

Engineering Instructor, the Technical Education Board of Wellington, New Zealand. Salary, £300 and £40 passage allowance. See advertisement.

Winders for direct-current and alternating-current work. Apply to Bruce Peebles and Co., East Pilton, Edinburgh. See advertisement.

RAILWAY AND TRAMWAY COMPETITION.

The chairmen of our large railway companies have of late years given many detailed statements as to the effect of tramways on the traffic returns of their systems. These statements are reflected in the report of the Board of Trade for 1904 as to the working of the whole of the railways within the United Kingdom. A few extracts from this report are given in this issue. The figures as to the total number of passengers carried for a series of years show that in the days of horse tramways the railways held the supremacy. In 1899 and 1900 there was little to choose between the total number using railways and tramways, but since then electric traction has put the tramways far ahead. In 1904 some seven hundred millions, or 65 per cent., more passengers used the tramways than the railways. The figures for the rate of increase on each system are even more striking, and indicate that the railway passenger traffic has nearly, if not quite, reached a maximum. With tramways, on the other hand, the yearly rate of increase is itself increasing. So far as mere numbers are concerned the result is bad for the railway companies, and it is obvious that the competition is by no means a fair one. They provide a service over lines laid on private rights-of-way secured at great cost, whereas the tramways use public streets without any further charge than is involved in the maintenance of a certain portion of the street surface. It is also the network of lines possible in public streets which gives the tramway the great advantage over its rival as a passenger distributing agent. This is shown by a comparison of the fares obtained from each passenger on the two systems. The third-class railway fares average 6·5d. per journey, which shows that the travellers on railways go for a considerable distance. The tramway fares, on the other hand, average between one penny and three halfpence, so that the rival systems may be compared to the feeders and distributors respectively of an electric power station. Considered on these lines, it would seem as though the future of our railways will be confined more and more to long-distance travel, and that the distribution of the population through industrial areas will be taken up entirely by tramways. With electrified railways vast improvements could be made on these lines in the intercommunication between adjacent towns, and between towns and definite tramway centres in the country. Another feature in the report which electrical engineers will do well to study is the respective gross income of the railways from passenger and goods traffic. These figures for 1904 show that some forty-eight million pounds were received from passengers, as against fifty-five million pounds from goods traffic. The earning power of trains used for the two services is also given as 48·09d. per train mile from passengers and 85·42d. per train mile from goods. Thus as a nation we spend about 15 per cent. more per annum for the transport of our raw materials, manufactured goods, and food than we do in travelling for business or pleasure. A large portion of this goods traffic must always be conducted on the railways, but here, too, there is a great opening for a cheaper distributing agent. Several of our larger tramway undertakings have instituted goods services, but the work done is infinitely small compared with what is possible in this direction. Electric traction will quicken the goods service and render it economical to increase the frequency of dispatch, which will attract business which the present railway facilities cannot meet. This is especially the case in industrial districts, where a goods service on electrified light railways or tramways will render the factories in outlying districts most valuable aid. The improvement

Digitized by Google

in the load factor on the lines from the diversity of load so obtained will render remunerative many lines which cannot be financially successful if run for passengers only. The above report indicates clearly the influence of electricity on the transport facilities of the country, and that by improved methods a greater traffic is dealt with than was possible some years ago. Co-operation between the present rivals, rather than competition, is to be desired for the public good.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

COST OF POWER PLANT.

SIR,—I note in a report which you give of the discussion of Mr. Snell's paper that you have reversed the figures of the cost of the installation of generating plant in private power stations. Mr. Snell stated that a private installation could not be erected under a cost of £45 per kilowatt, and as I considered that his estimate was altogether too high, I gave him certain figures, which are actual costs of installations which my firm have in hand at the present time, and these are as per copy attached, marked No. 1 Mr. Snell objected to my figures both as regards cost of plant and the cost of production, and unfortunately I was not present at the discussion, but I sent a communication to the North-East Coast Institution, of which the attached, marked No. 2, is a copy.

In conclusion, I can only state that the figures which I give are not imaginary figures, but are costs well on the high side of actual work in hand. There is no doubt that power stations have an immense future before them when they can supply current at prices within measurable distance of what it can be produced in private stations, but it is only right that consumers should know what the cost of a private installation should be if they had to consider the merits of either producing themselves or purchasing from the supply company.—Yours, etc., W. C. MOUNTAIN.

[This matter is referred to again in our front notes.—ED., *E. E.*]

HOTEL WIRING.

SIR,—I have just read your article on hotel wiring on p. 229 of your issue of the 18th ult., and trust a little criticism and additional information will not be out of place. I quite agree that on the Continent the various convenient adaptations at the disposal of wiring contractors are better appreciated and oftener brought before the notice of hotel proprietors than they are at home, although such have a fair adoption here also.

Fig. 1 of your article is an old friend to wiring contractors at home, and large hotels here were so fitted as far back as 1891. Anything a visitor finds a convenience at an hotel would be a large factor in inducing him to come again and also recommend the hotel to his friends, as novel applications remain in mind and are the means of providing good advertisements for the proprietor. Your remarks *re* the ugly appearance of treble flexible on porcelain insulators would have little interest here, as such wiring is not very general, although no doubt in the near future it will be made good use of. Fig. 2, I fear, is of little use, and would be unpopular on account of the necessity of both switches having to be placed in their "off" positions before the lamp can be extinguished. Fig. 3 is an old friend up to a certain point—viz, a two-way and "off" position switch controlling either of two lights. The same objection as in Fig 2 also exists here—viz., that switch S must be in its "on" position before lamp L_2 can be lighted by the two-way and "off" position switch, U. Fig. 4 is the most convenient and economical adaptation, the two-way switch, U_2, being usually placed near the door, the lamp, L_2, controlled by it being placed over the dressing table; the three-way switch is placed near the bedside, and controls both, only one, however, being in use at a time. It will be obvious that this arrangement is a most economical one for hotel proprietors to adopt, as it prevents considerable waste of current by users.

This method of circuit wiring is at present being installed in the King's Sanatorium now building at Midhurst, Sussex. My diagram (*a*) herewith will show the connections a little clearer, two-way and three-way switches as used being of tumbler type.

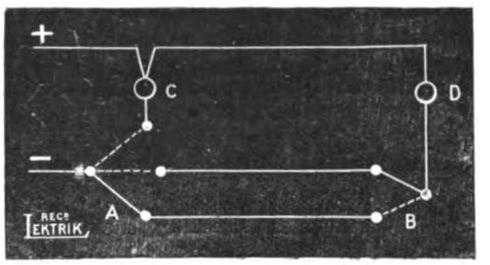

Diagram (*a*).

Fig. 5 is simply a three-way switch with "off" positions, controlling separate circuits.

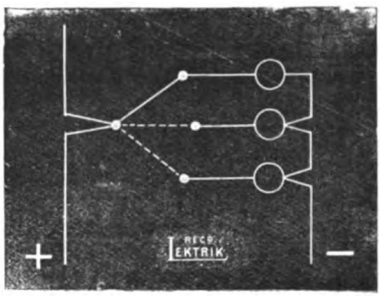

Diagram (*b*).

My diagram (*b*) will show a three-way tumbler switch controlling three separate lamps, a single-way switch being, of course, necessary to break the "common" wire. My diagram (*c*) shows the circuit connections employed for lighting or extinguishing *either* of two lights from two positions. Three three-way tumbler switches are used, two of them being coupled together, as is commonly done for double-pole switches.

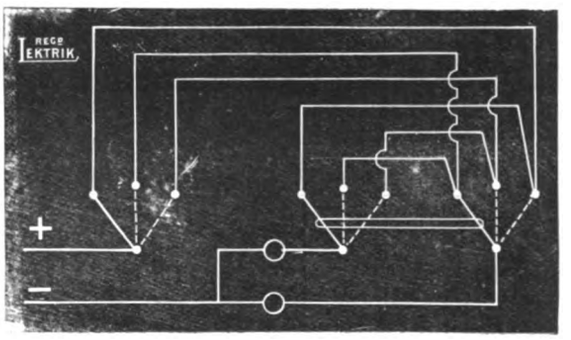

Diagram (*c*).

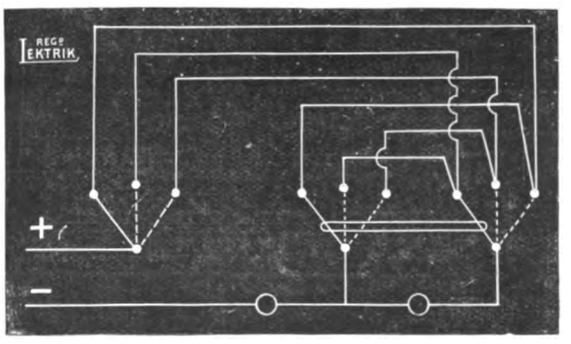

Diagram (*d*).

Diagram (*d*) shows a similar arrangement, giving (1) one lamp full, (2) two lamps series (dim light), (3) "off"

Digitized by Google

position, all from either position. Diagram (*e*) shows a similar adaptation using a double-filament lamp, the circuit

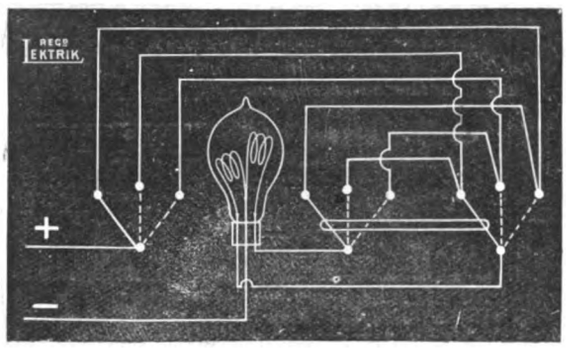

Diagram (*e*).

allowing *either* filament being lighted or both extinguished as desired, the small filament being conveniently used as a

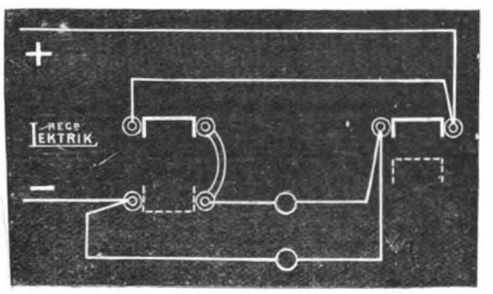

Diagram (*f*).

night-light. Diagram (*f*) shows how a single-way and a two-way switch may be connected to give the following results: (1) one lamp only, (2) two lamps parallel, (3) two lamps series, (4) "off" position. Diagram (*g*) shows how

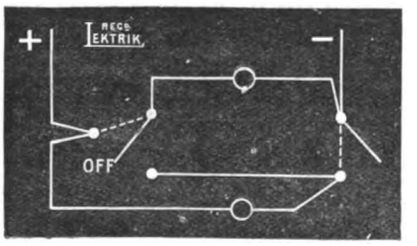

Diagram (*g*).

a single-way switch and a two-way switch with "off" position may be connected to give the following results: (1) one lamp, (2) another lamp, (3) both lamps in parallel, (4) both lamps in series, (5) "off" position. In the last two applications, if metal covers be used, it is advisable to have them lined with insulating material for the two-way and two-way and "off" switches used.

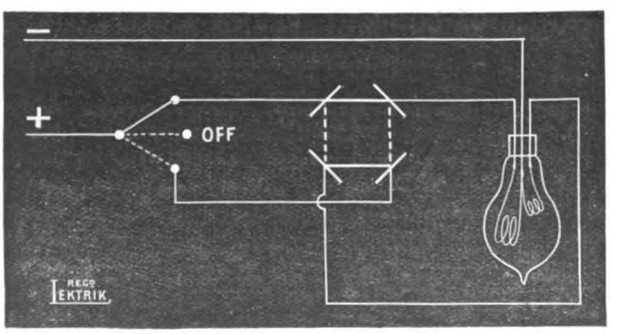

Diagram (*h*).

Diagram (*h*) shows another useful system for hotel bedroom wiring. A two-filament lamp is used (usually 16 c.p. and 1 c.p.). A "duplex" two-way and "off" tumbler switch is fixed near the door, and a "pivot intermediate" tumbler switch near the bedside. The latter switch allows either full light or a dim light for night-light use. The "duplex" switch at the door provides (1) full light, (2) dim light, (3) "off" position for use during daytime or if the room is required left in darkness. Trusting the foregoing will prove of interest to your readers—Yours, etc.,

GUS. C. LUNDBERG.

STATIC ELECTRICITY IN PAPER.

SIR,—I feel very grateful to "M. M." for his suggestions regarding above, but one device he refers to—that is, a series of metallic brushes and connected to earth—has been in operation here for some years, but without effect. He also suggests to reduce the friction on the paper, but the machine travels at a high speed—350ft. per minute—consequently the paper is very quickly dried. Might not a great deal of the electricity be generated by evaporation? I think neutralising it would be the only way out of the difficulty. How would it do to insulate the last roll on the machine, which is a copper one, from the frame, and make it part of an alternating-current lamp circuit? Would that neutralise it? If you can find space in your valuable paper, I shall be glad to hear more on the subject.—Yours, etc., JAMES WOOD.

6, Bank-street, Woodside, Aberdeen.

[N B—The last suggestion of our correspondent would not be serviceable, due to the insulating property of paper. Any useful means of removing the static charge caused by friction must operate on the surface of the paper on its way to the final roll. Perhaps Mr. Wood does not realise that the effect complained of is largely caused by the machines on which the paper is used.—ED., *E. E.*]

UNITS UNACCOUNTED FOR.

SIR,—I beg to call your attention to an inaccuracy which occurs in the Tonbridge electricity accounts in your issue for Sept. 8. You will observe that the total quantity o power generated is 156,582 units, and the total quantity accounted for is exactly the same. This is a state of affairs which is too happy to exist. The amount of power generally given under the "Not accounted for" heading includes all losses in transmission, leakages, etc. Probably the total quantity generated is given wrongly.—Yours, etc, E. P. H.

[We had seen the inaccuracy noticed by our correspondent in the accounts for the Tonbridge electricity supply undertaking. On looking through the same again, we find that the loss in mains (5,800 units) is included under the "Quantity used on works." This is a wide reading of the accepted term which, we think, is not justified. Also it is evident that leakage and discrepancies in meter readings must also come into this item, which should appear under "Quantity not accounted for."—ED. *E. E.*]

RAILWAY RETURNS.

The annual returns of the capital, traffic receipts, and working expenditure of the railway companies in the United Kingdom for 1904 have just been issued, together with a report on the same addressed to the Secretary of the Board of Trade. This report is a complete statement correcting the figures issued early in May last. As foreshadowed in the report for 1903, additional returns have been obtained from railway companies whose lines are worked wholly or in part by electricity, but the form in which these returns were collected being a tentative one, it is not proposed to publish the information thus acquired. It is hoped, however, that valuable returns relating to railways worked, or partially worked, by electric traction will be available for publication in the reports relating to future years. In this report there appear figures for those railways which are worked throughout by electricity, but the statistics refer to traffic only. The democratic tendency of the age is shown by a further falling off in first and second class passengers, which is more than counter-

Digitized by Google

balanced, as far as numbers, in the increase in the third-class. The average receipts per passenger are for first-class 23·6d., for second-class 11d, and for third-class 6·5d. These figures for the whole of the United Kingdom clearly show that the bulk of the railway passenger service is for short-distance travellers. The increase in the number of third-class passengers was rather greater in 1904 than in 1903, but it was still small as compared with the annual increases shown by the returns for years previous to 1902. That this falling off in the rate of increase is due, in a great measure, to the increasing competition of tramways, may be deduced from the following comparative statement:

Year.	Third class railway passengers (years ended Dec. 31).	Increase. Number.	Increase. %	Tramway passengers (years ended June 30).	Increase. Number.	Increase. %
1896	888,604 000	—	—	759 466,000	—	—
1897	935 160,000	46,556 000	5·2	788 570 000	29 104,000	3·8
1898	963 674 000	28 514,000	3 0	858 486 000	69,916,000	8 9
1899	1,003,996,000	40 322,000	4·2	924,820 000	66,334,000	7·7
1900	1,038,873,000	34,877,000	3·6	1,065 374,000	140,554,000	15 2
1901	1,068,919,000	30,046,000	2·9	1,198,227,000	132 853,000	12·5
1902	1 080 625,000	11,706,000	1·1	1,394 453,000	196,226,000	16·4
1903	1,086,205,000	5,580 000	0 5	1,681,949,000†	287,496,000	20·6
1904	1,092,649,000	6,344,000	0·6	1,799,343,000‡	—	—

It will be seen that the number of tramway passengers carried in 1900 was greater than the number of third-class railway passengers carried in that year, and that the increases in subsequent years have been proportionately much greater in the case of the tramway passengers than in the case of the railway passengers. The date to which the returns relating to tramways and light railways (street and road) were made up has recently been altered, as stated in the footnote appended, and consequently the increase in the number of passengers during the year ending June 30, 1904, cannot be ascertained. It must be borne in mind that the increase in tramway passengers in the year ending June 30, 1903, is somewhat abnormal, owing to the inclusion for the first time in the returns for that year of particulars relating to public road lines authorised under the Light Railways Act, 1896.

The following statement shows the average receipts per train mile, distinguishing goods and passenger trains, during each of the last six years:

Year.	Receipts per train mile. From passenger traffic. d.	From goods traffic. d.	From passenger and goods traffic. d.
1899	48·36	70·29	58 06
1900	49·08	71·06	59·01
1901	49·61	73·25	59·92
1902	49·50	77 03	61·27
1903	49·21	82·55	62 79
1904	48·09	85 42	62·74

The ratio of working expenses to gross receipts for the year stood at 62 per cent. as last year. The actual average expenditure per train mile for the two years was as shown in the table below:

Expenditure on account of—	Cost per train-mile. 1904. d.	1903. d.	Increase (+) or Decrease (−) in 1904. d.
Maintenance of way	6·40	6·41	(−) 0·01
Locomotive power	11·18	11·28	(−) 0·10
Rolling stock	3·41	3·41	—
Traffic expenses	12·37	12·40	(−) 0·03
General charges	1·59	1·58	(+) 0·01
Rates and taxes	2·86	2·73	(+) 0·13
Government duty*	0·22	0·23	(−) 0 01
Compensation to employés	0·10	0 09	(+) 0·01
Personal injuries to passengers	0·08	0·10	(−) 0·02
Damage to goods	0·24	0·27	(−) 0·03
Legal and parliamentary expenses	0·18	0·20	(−) 0·02
Miscellaneous	1·20	1·13	(+) 0·07
Total (exclusive of expenditure on steamboats, docks, harbours, and canals)	39·83	39·81	(+) 0·02

* For Great Britain only. The railway passenger duty is not charged in Ireland.

† Particulars relating to public road lines authorised under the Light Railways Act, 1896, included for the first time.

‡ These figures represent the number of passengers carried by street and road tramway and light railway companies during the year ending Dec. 31, 1903, and by street and road tramways and light railways owned by local authorities during the year ending March 31, 1904. The period to which the figures relate consequently overlaps to a considerable extent the one to which the 1903 figures relate.

The passenger receipts per mile of line averaged £4,586 for the year. This figure is not directly comparable with that we give in our electric tramway returns each week of receipts per mile of single track. About one half of the total mileage of railways, or 12,590 miles out of 22,654 miles, have two or more tracks. Still, if this is allowed for, it will be seen that the traffic returns per mile of tramway track is not very different in the average to that from railways. The rest of the above report will repay careful study by those interested in the electrification of railways.

THE EDDY-CURRENT BRAKE FOR TESTING MOTORS.*

BY D. K. MORRIS, PH D., AND G. A. LISTER, ASSOCIATE MEMBERS.

Introduction: Methods of Motor Testing in Use.

The testing of a motor for efficiency and suitable rating requires that the motor shall be subjected for short or long periods to a measured load of any desired amount. Steady maintenance and accurate measurement of the load are necessary, while the means of applying it should in no way affect the conditions under which the motor works. It is interesting to review the methods of motor testing which have been proposed, and generally to consider the possible methods of absorbing and measuring the energy of a motor.

Table I.—Methods of Motor Testing.

Nature of energy-absorbing apparatus.	(1) Energy utilised.	(2) Energy dissipated (absorption brakes).
Mechanical.	Lifting weights — *e.g.*, in determining combined efficiency of cranes or hauling gear.	(*a*) Block (Prony, etc.). (*b*) Rope. (*c*) Band (Soames, etc.).
Fluid.	Pumping — *e.g.*, in determining combined efficiency of motor pumps.	(*a*) Water (Froude). (*b*) Air friction.
Electric.	(*a*) Load taken up in separate generator of known efficiency. (*b*) "Hopkinson" methods as below.	(*a*) Eddy currents only. (1) Fixed field. (2) Revolving field. (*b*) Eddy currents and hysteresis. (1) Fixed field. (2) Revolving field.
	Losses supplied.	
	Mechanically. | Electrically.	
	By belt. By direct-coupled motor. | Parallel system. Series system.	

Table II.—Electric Testing Brakes.

—	Eddy currents only.	Eddy currents and hysteresis.
Fixed field	(*a*) Air-cooled (Pasqualini, 1892; Grau, 1900; Siemens and Halske) (*b*) Water-cooled	(*a*) Air-cooled (Rieter, 1897) (*b*) Water-cooled
Revolving field	(*a*) Air-cooled (*b*) Water-cooled	(*a*) Air-cooled (Rieter) (*b*) Water-cooled (Korting)

They group themselves naturally as in Table I., according to the nature of the device employed, whether mechanical, hydraulic, or electrical, and to the method of absorbing the energy, whether the latter is or may be utilised, or whether it is immediately dissipated. In Prof. Threlfall's calorimetric method the motor output is not measured directly, but is derived from the input by subtracting the measured losses. Transmission dynamometer methods are properly

* Paper read before the Birmingham Local Section of the Institution of Electrical Engineers.

Digitized by Google

applicable only to the testing of generators, while the "slowing-down" method of Dr. Sumpner, not being one in which the motor is continually loaded, is not classed in the table.

The electrical methods in which the energy is immediately dissipated may be classified as shown in Table II. In all the above eddy-current brakes the revolving portion only is carried by the motor spindle, the fixed portion being supported on either circular or knife-edge bearings.

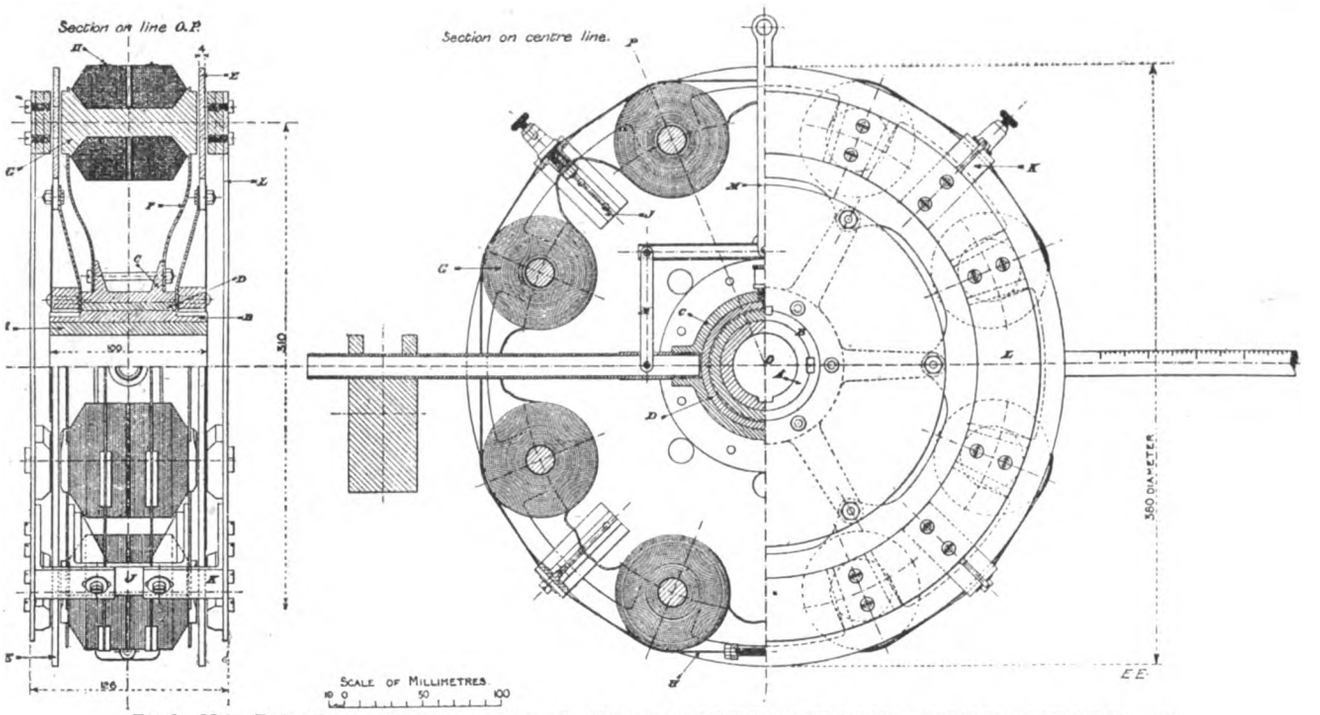

FIG. 1.—Motor-Testing Brake—Eddy Current Type. For Motors up to 5 B.H.P. at 1,000 R.P.M., or 7½ B.H.P. at 1,750 R.P.M., with overload capacity of 25 per cent. in each case.

The opportunities of applying methods in which the energy may be utilised are few. For, of these, mechanical and fluid methods are out of the question for general testing, and electrical methods necessitate the use of auxiliary machinery. Again, to test a motor by coupling it either directly or by belt to a generator of known efficiency is at the best but an indirect proceeding. Any variation of the conditions as regards speed, temperature, or state of bearings will alter the generator efficiency, and there is always a small, and usually unknown, loss in belt driving. The "Hopkinson" method in its various forms requires two exactly similar machines. Where these are available, this method has no rival, unless in the case of small machines, for which the parallel Hopkinson test may require abnormal conditions of running. Of the class in which the energy is dissipated, air friction brakes are cumbrous, while the water brake is expensive in construction and ill-suited for testing small motors, although excellent for large powers. Mechanical and eddy-current brakes are much superior for ordinary testing.

ADVANTAGES OF EDDY-CURRENT BRAKES.

The eddy-current brake has many advantages over the band or rope methods of motor testing. Among these are (*a*) sensitiveness combined with convenience of adjustment to exact balance; (*b*) uniformity of load and exact constancy after final temperature conditions have been reached; (*c*) heat produced in energy-absorbing element not conducted to bearing; (*d*) absence of wear; (*e*) retarding torque only occurs.

The first three arise from the nature of the friction employed, and from the simplicity and fineness of rheostatic control. The advantage referred to in (*c*) is one of great importance. The continual stream of air outwards past the copper disc carries away the heat in a remarkable manner, so that the copper disc may be very hot, indeed, for long periods, while the adjacent bearing remains quite cold. The nature of the stresses, too, permits of a relatively perfect thermal isolation of the disc as compared with a pulley rim. Methods based upon mechanical friction demand water cooling where *time* tests have to be made on motors above 1 h.p. or 2 h.p. With specially large pulleys this limit can, of course, be raised. No such limit exists with the eddy-current brake. With such apparatus, correctly designed, the absorption capacity appears to be determined only by the heating of the magnetising

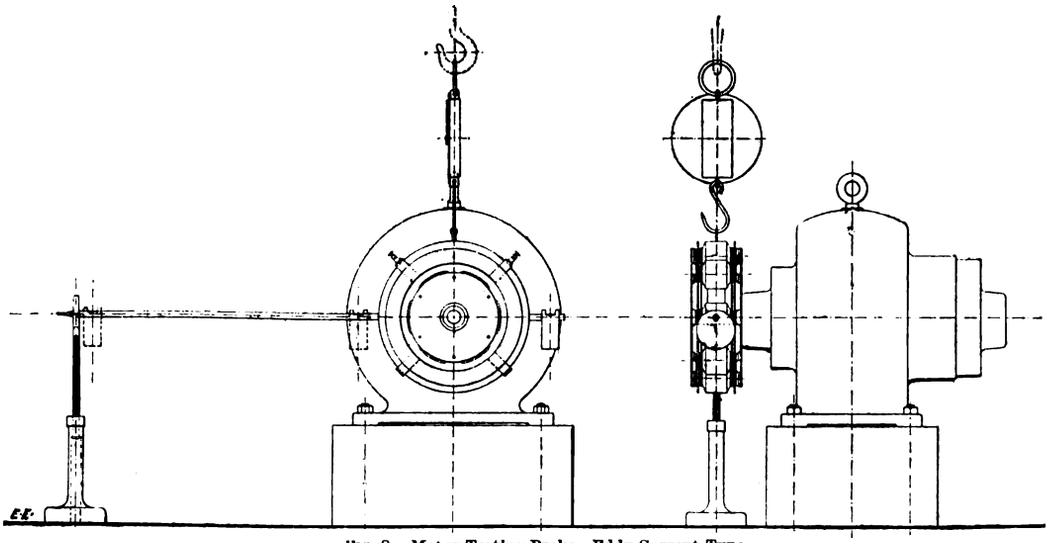

FIG. 2.—Motor-Testing Brake—Eddy Current Type.

Digitized by Google

coils. The mechanical forms of brake combine great simplicity with considerable sensitiveness, but the advantages enumerated above have sufficed to direct attention to the construction of the eddy-current brake, several patterns having been produced.

New Design of Eddy-Current Brake.

The types of eddy brake on the market, however, have not been very widely used, mainly on account of the high initial cost and the difficulty of applying them to various sizes and types of motors. They are constructed on one of the following principles: (1) The revolving element is secured to a spindle, one end of which is coupled to, or belt-driven from, the motor shaft. This brake spindle revolves in bearings carried by an independent frame, which also carries by means of ball-bearings the floating portion of the brake. (2) The revolving element is secured direct to the motor shaft, the fixed portion being provided with knife-edges, and mounted on a separate frame. In the former case a correction of an uncertain nature arises on account of the friction of the bearings, and probably on account of air friction, while in the latter either the brake or the motor has to be specially mounted, that the centres may be brought approximately into line. In such brakes, also, end play should be minimised.

may be tested with this brake with an accuracy not hitherto possible. In cases where lifting gear is not available the suspension and balance could be carried by a special frame provided with screw and hand-wheel. For ordinary testing the whole brake can very well be carried on the motor spindle without suspension.

The construction described has, therefore, the following additional advantages without in any way sacrificing those enumerated: (*f*) apparatus self-contained, no separate frame required—an advantage over all other practical types of brake; (*g*) brake is completely astatic; (*h*) air-friction error is practically eliminated; (*i*) pressure on motor bearing during test may be adjusted to any desired amount, independent of the load.

Detailed Description.

The revolving discs, E, are made of high-conductivity hard-rolled copper. They are supported by a thin steel plate and steel arms on the outer and inner sides respectively, each hub being keyed to the bush B. Between these discs is the casting, C, which is fitted with a gunmetal bush D bored to suit the bush B. Into this casting are screwed two tubes, the shorter carrying the counterpoise, and the longer constituting the lever arm. This arm is marked with a scale of feet divided into tenths and

Fig. 3A. Flux in yoke ring with a constant magnetization of 3,500 ampere-turns per coil.

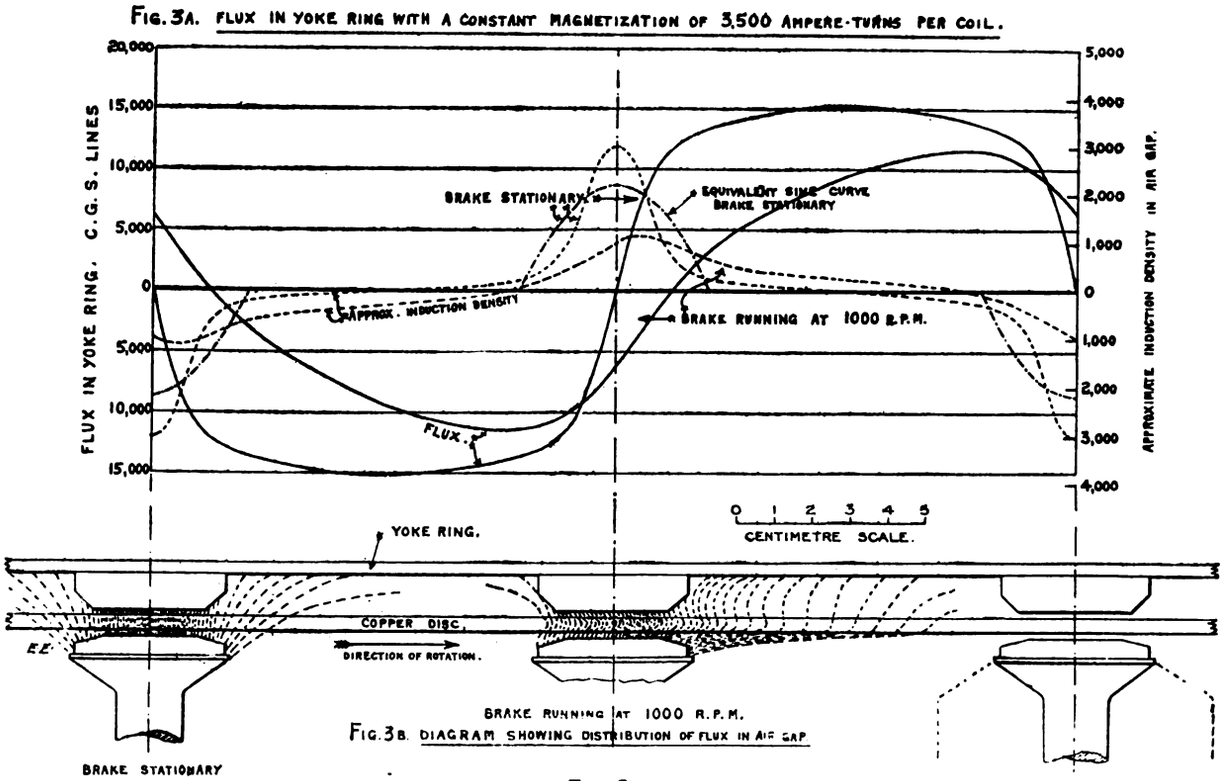

Fig. 3B. Diagram showing distribution of flux in air gap.

Fig. 3.

To surmount these difficulties, the authors, in designing a brake for the electrical laboratory of the University of Birmingham, decided to entirely dispense with separate bearings or frame. This brake is illustrated in Fig. 1. It is intended to be mounted on the motor shaft in place of the ordinary pulley. The fixed portion of the brake is carried by the revolving system, and though there is friction at the bushes, B and D, this small load is duly represented as torque on the brake lever. A similar argument applies to the air friction. Mechanical and electrical symmetry are insured by the use of two copper discs, one revolving on either side of the magnetising coils. This doubles the capacity of the brake for a given diameter, and incidentally renders it completely astatic. A multipolar design was employed, since in this case the weight is less than that for a two-polar design. Fig. 2 shows the brake mounted on the spindle of an electric motor, and indicates the manner in which the pressure on the motor bearing may be adjusted. The brake is provided with a link suspension, so that an upward pull gives rise to no twisting moment. This suspension is attached to a spring balance, which can conveniently be carried by the hook of the crane or blocks serving the testing bed. By means of the lifting gear the pressure on the bearing may be reduced to nothing, or it can be given any desired value. Bearing friction in motors

hundredths of a foot, the maximum leverage being 3ft. The brass plates, F, are bolted to the casting, C, and carry at their circumference the magnet coils, G. These coils, which are eight in number, are securely held in position by the steel wires, H. Each consists of a wrought-iron core wound with 1,400 turns of No. 20 S.C.C. copper wire. The resistance of each coil is 5·1 ohms when cold. There is a ventilating duct at the middle of the coil. The aluminium castings, J, act as distance pieces, the two upper ones being fitted with insulated terminals. Secured to these castings by set-pins are the aluminium castings, K, which carry the external yoke-rings, L. A slotted hole in the castings, K, allows the length of the external air-gap to be adjusted. The length of the internal air-gap is fixed, and in consequence of the rigidity and smooth running can be kept short. Steel bushes, A, are turned to suit the inside of bush B, into which they are keyed. They are bored out to various sizes to suit the spindles of the motors which have to be tested. The suspension links, M, are fitted to the graduated lever and to the counterpoise lever at equal distances from the centre. Accurately adjusted sliding weights of 2½lb., 5lb., 7½lb., and 10lb. are used. After completion the brake was supported on a central knife-edge, and the counterpoise lever loaded until an accurate balance was obtained.

EXPERIMENTAL RESULTS OBTAINED.

1. A test to determine the result of reducing the number of magnets showed that the braking effect is practically proportional to the number of coils excited. The slight reduction observed was probably due to the increased length of the iron portion of the magnetic circuit. In other words, the braking effect depends only on the total flux cutting the copper, and is independent of the number of points at which it may be applied.

2 The removal of the external yoke-rings resulted in a reduction of the absorption capacity to about 50 per cent. of the normal for a given number of ampere-turns per coil.

3. The torque produced by bearing and air friction alone (the magnets being unexcited) was found to be about 0·3 foot-pounds at 500 r.p.m. This increased to 0·365 foot-pounds at 1,250 r.p.m.

4. At moderate excitations, such as 4,000 ampere turns per coil, the horse-power absorbed increases, except at first, nearly with the speed up to 1,000 r.p.m. Above this speed, however, there is a noticeable falling off. At low excitations, such as 1,500 ampere-turns per coil, the falling off occurs at about 600 r.p.m. This failure to reach proportionality is due to increased distortion of field at high speeds, and consequent reduction of resultant flux. Fig. 3A represents the flux (obtained ballistically) in one of the yoke-rings with the brake stationary, and also when running at 1,000 r.p.m., the excitation being constant at 3,500 ampere-turns per pole. The flux which usefully cuts the copper may be taken as that which actually arrives at the yoke-ring. The dotted curves, which are determined from the flux curves, represent the approximate induction density in the air-gap in each case. It will be seen that, on the average, the flux is shifted forward in the direction of rotation. This is represented in Fig 3B.

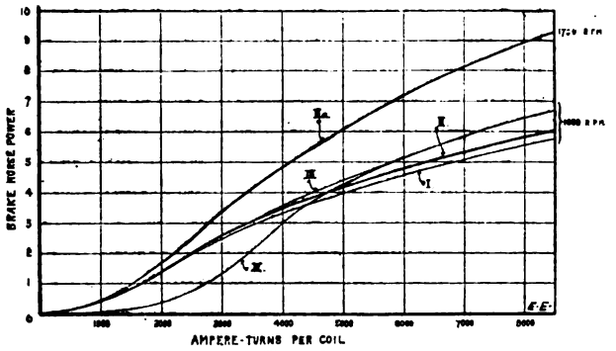

FIG. 4.

5. The brake was originally made with a plain yoke-ring without pole-pieces. Its performance under these conditions is shown in Fig. 4, Curve I, abscissæ representing ampere-turns per pole, and ordinates the horse-power absorbed. The addition of pole-pieces 1cm. deep, and having a radial length slightly less than the diameter of magnet core, somewhat increased the efficiency of the brake, as indicated by Curve II. The best position for the pole-piece was found to be 5mm. forward of the magnet coil, but the effect was not sufficient to warrant their being permanently placed in this position.

6. An attempt to prevent the flux from being dragged off the pole-pieces, and so prevent excessive lengthening of lines, and consequent reduction of field strength, was made by winding the yoke-rings with additional magnetising coils situated between the pole-pieces. There were 16 coils of two coils per magnet, each consisting of 25 turns of No. 18 D.C.C. copper wire. The effect was very noticeable, as will be seen on reference to Fig. 4, Curve III., which shows the effect of a constant current in the main coils giving 3,500 ampere-turns combined with increased excitation applied by means of these supplementary coils, up to a total of 6,000 ampere-turns. Curve IV. shows the result of a constant excitation of 2,000 ampere-turns maintained by the yoke-ring coils, supplemented by currents in the main coils. The result of these two curves is to show that up to an excitation of, say, 5,000 ampere-turns, the maximum effect will be obtained by using the main coils only. Above this figure, however, the strength of the eddy currents in the discs tends to cause excessive distortion of the field, and a great advantage will result by transferring a large portion of the energy supplied to the brake to the yoke-ring coils. The advantage, however, probably does not warrant the extra complication.

7. It was found that the braking effect for a given excitation is not perceptibly dependent upon the temperature of the copper discs. This shows that any decrease in the eddy currents due to increased resistance of path is counteracted by the consequently reduced distortion.

8. Experiments carried out with different lengths of air-gap emphasised the necessity of keeping this as small as possible. When absorbing 5 h.p. at 1,000 r.p.m., a reduction in the air-gap from 10mm. to 8mm. reduced the current required by 15 per cent., thus resulting in a saving of power of rather more than 30 per cent.

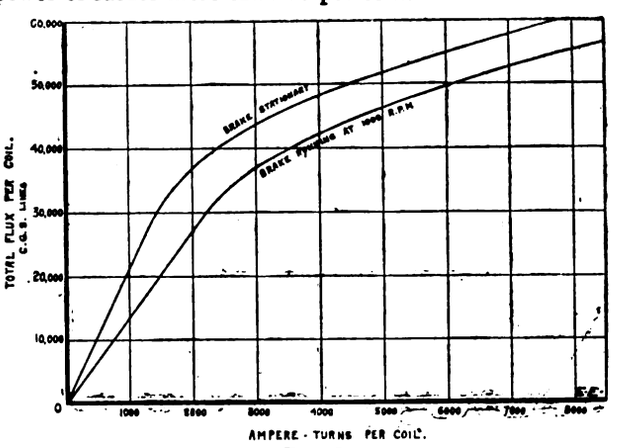

FIG. 5.

9. Fig. 5 shows the variation of flux with excitation both with brake stationary, and when running at 1,000 r.p.m. The thickness of the copper disc is 4mm., and the length of air-gap between pole-tips approximately 9mm. In each case the flux was measured at the centre of the magnetising coil.

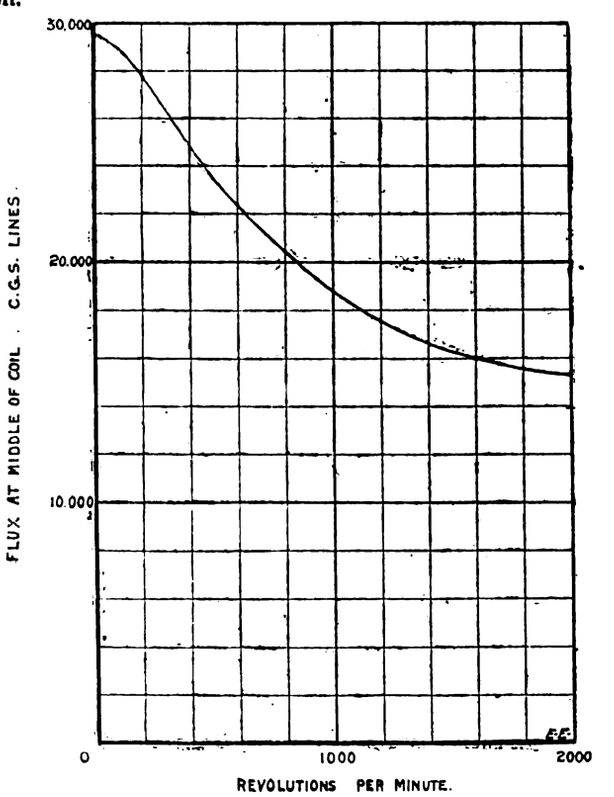

FIG. 6.

10. Fig. 6 shows the variation of flux with speed, the excitation being constant at 1,400 ampere-turns per coil. The measurements were taken at the centre of the coil.

11. As a result of theoretical considerations, the brake was tried with copper discs of section shown in Fig. 7. This section enables the length of the air-gap to be considerably reduced, while at the same time affording a high-conductivity path for the eddy currents in a circumferential direction. The results obtained are given in Curve V. (Fig. 4). *(To be continued.)*

ELECTRIC TRAMWAY v. MOTOR OMNIBUS

Oxford Reports

In our last issue we published reports by Mr. Stephen Sellon and Mr. W. Worby Beaumont respectively as to the best system of replacing the existing horse tramways in Oxford. The town clerk sent to each expert a copy of the other expert's report, with a request for further details. These supplementary reports are remarkable for their conciseness, and also for humour. Mr. Stephen Sellon's further report to the town clerk is dated Aug. 17, and reads:

Dear Sir,—I have to acknowledge your letter of the 14th inst., with the enclosures mentioned. The tramway company's figures now sent might have enabled me to make a more detailed division of the probable future traffic between the various routes, but their consideration does not affect my general conclusions. Replying to your questions on my own report, I may say that I do not recommend a composite system of tramways and motor omnibuses In my view all the extensions mentioned will support a service of not less frequency than 15 minutes, and in such cases the tramway capital expenditure is justified. A broken service involving changing from one vehicle into another always involves the loss of a large amount of traffic, varying, in my experience, from 30 to 60 per cent., whether by transfer from tramway car to tramway car or from motor 'bus to tramway car. My figures for working cost provide fully all current repairs, and also for such renewals as will accrue during the period of repayment of the loan. They do not cover such an amount as will provide a new tramway and equipment at the end of the loan term It will be apparent that when an undertaking is charged with the repayment of loan capital during a fixed period that to charge it also with an annuity for the purpose of providing another equal, or nearly equal, amount, under the name of depreciation, is virtually charging the first generation of users with twice their share of the capital expended on the undertaking—a course neither equitable nor necessary. Any provision of the kind that may be prudent should properly be made out of the profits of the undertaking. For financial reasons I should recommend any municipality to devote a large proportion of the profits realised to making such provision—but I cannot class such payments with working expenses. I have come to the conclusion that the necessary capital expenditure to construct a tramway along Woodstock-road would not at present be justified.

I have carefully read and considered Mr. Worby Beaumont's report. A controversial criticism thereof is not in my intention, but the first point which strikes me as significant is the complete silence on the all-important point of working expenditure. I think I may usefully suggest certain considerations to the committee which seem to have been but slightly touched on therein. The cost of working the service and its financial results seems to me a matter on which the Council needs some guidance. It may be that there is no desire to make large profits, but I presume that neither is it desired that the undertaking should be a charge upon the rates. So far as present information goes, the cost of running a motor omnibus will be more than the probable earning capacity of the vehicle, certainly more than I have assumed that the tramcar will earn in such a town as Oxford. What motor omnibuses will really cost to maintain is not yet known, and will not be for two or three years to come, but it is certainly true that in some cases their use is being discontinued on account of the cost and the time out of service involved in repairs. The working costs put forward are not the whole of the cost. The capital expenditure in providing a suitable road surface and the cost of maintaining it in good condition should properly be charged in due proportion against the omnibus service as I have charged the capital and maintenance of the track to the tramway undertaking. It appears to me that the combination of motor omnibuses and macadamised roads in the city of Oxford would create an intolerable dust nuisance, and that some form of wood, asphalt, or stone pavement would be imperative. I need hardly point out that either of these will cost more than a tramway track along the same mileage of route. In fact, the paving of a tramway track is the most expensive item in its construction. The remarkable wear of all road surfaces by rubber-tyred motor vehicles is well attested.

I advise the Council that in considering Mr. Worby Beaumont's suggestions the additional capital and maintenance expenditure on their roads must be taken into account as a most important item. As regards the question of amenities. Exactly which of the world-famous charms of Oxford, which of its rich and varied historical associations, would be injured by a tramway car, but remain undamaged by a motor omnibus, I find it very hard to imagine. It will be well known to the Council that the electric tramway has not been thought incongruous with the conditions of many of the most ancient and picturesque seats of learning on the Continent, that cities like Rome, Milan, Dresden, and Munich, to mention the first that come to mind, have found such modern conveniences consistent with the maintenance of ancient traditions and modern charm. Such experiences suggest that the distinctive charms of Oxford will suffer no loss. On the ground of general comfort and convenience, I am quite clear that in any comparison the tramcar will take the first place if either the passengers or the residents on the route are considered. I have before me copies of memorials and letters from ratepayers addressed to the Town Council of Eastbourne, protesting against motor omnibuses being run on certain proposed routes, asking for a reduction in the number run on actual routes. The reason adduced being noise, offensive smell, and the insufferable nuisance of clouds of dust, troubles from which the electric tramcar is free, and which the Council will perhaps consider to be as destructive of the amenities and comforts of life in the city; and I suggest that an inquiry on this point might well be addressed to the Corporation of Hythe. After full consideration, therefore, of Mr. Worby Beaumont's report, I adhere to my own recommendation of the adoption of electric tramways. If Mr. Beaumont is correct, and that the population will be carried by a proper system of communication 100 times over in the course of the year, then the profits will be greater than I have estimated.—Yours faithfully, (Signed) STEPHEN SELLON.

In reply to a letter from the town clerk, Mr. Beaumont sent the following, dated Aug. 16:

I send herewith a supplement to my report on the above. I received the copy of my report and of Mr. Sellon's In the accompanying supplementary report I have not and need not refer to Mr. Sellon's report, but I notice that his estimated expenditure is £130,000, and net balance of receipts and expenses on this is estimated at only £3,229. If to the estimated cost is added the cost of acquisition of the existing tramways, and if some value be placed on the business and time losses resulting from breaking up eight miles of streets and roads, and, further, if the probable considerable cost of interference with pipes, etc, where conduit or surface-contact systems are used, be taken into account, there would seem to be grave reasons for thinking the tramway project an expensive one.

The supplementary report is as under:

Dear Sir,—I duly received your letter of the 14th inst., and in that which follows I now send replies to the questions raised by the Tramways Committee—namely, (*a*) cost of working and maintenance of motor omnibuses; (*b*) how soon they would need replacement; (*c*) how much they would earn at suggested fares. I base my estimates on the returns sent me from the City of Oxford and District Tramways Company, the following results from an examination of these returns and from the directors' report and accounts to Dec. 31, 1904. The time allowed for the double journey by the tramcars on the several routes varies from 30 to 48 minutes. The time allowed for the 'bus double journeys is 60 minutes. These respectively give about 36 and 24 single journeys per day for a 12 hours' day. Taking only 12 hours per day, and 365 days per year, this gives the following as the passenger-carrying results of the service hitherto in use.

Digitized by Google

	Per day.	Per single journey.
Passengers carried in 1905 by tramcars	600	16·45
Passengers carried in 1905 by omnibuses	394	16·40
Passengers carried by Iffley-road 'buses	450	19·00

From this it will be seen that the average patronage of the 'buses per single journey is as great as that of the tramcars, although the number carried per car mile, as hereafter appears, is greater than that per 'bus mile. The returns show that the passengers carried by the 'buses on the Broad-street and Iffley-road route per journey exceed the average number carried per single journey by the tramcars, although the average number carried by the Cowley cars per journey is greater. It is thus shown by actual experience in Oxford that, large as is the traffic considering the service, the omnibus has proved itself capable of carrying more passengers per seat provided, or to have a larger percentage of paying load, than the tramcars. With the present service the average receipts per passenger have been apparently—by tramcar 1·16d. per passenger, by 'bus 1·26d. per passenger. From the returns of the tramway company it appears that the passenger receipts per journey have been: receipts per journey per car, 19d.; receipts per journey per 'bus, 20·6d. Apparently the receipts and expenses per mile run have been:

Receipts per car mile	13 2d. per mile.
Receipts per 'bus mile	9 6d. ,,
Receipts, average car and 'bus	12·7d. ,,
Expenses, average of cars and 'buses	10·5d. ,,
Profit per mile by cars and 'buses	2·2d. ,,

On these receipts and expenses and on this profit per car and 'bus mile the tramway company have apparently (with their very light cars, light on the permanent way) been paying about 5 per cent. per annum. A similar number (16) but of faster and more commodious motor omnibuses, which would not lose their time by waits at turnouts, would, I believe, meet the requirements for greater accommodation up to about 30 per cent. increase, when greater requirements would be met by simply adding to the number of 'buses. Based upon the experience now available, the average cost of running motor omnibuses would be:

Running Expenses—90 miles per day (per 'bus mile).	
Petrol (6⅝ miles run per gallon at 6d.)	0 90d.
Oil and grease	0·28d.
Tyres	2·06d.
Driver and conductor	1 75d.
Repairs and renewals	0 55d.
Depreciation at 20 per cent. charged to 300 days	1·35d.
Washing, stabling, gas, water, sundries	0·50d.
Total running expenses	7·33d.
Traffic Expenses.	
Licenses, ticket services, superintendence, compensation, lighting, and sundries	0·45d.
General Administration.	
Law, rates, taxes, office and building insurances, printing, manager, engineer, etc.	0·35d.
Insurance of 'buses against fire, accident, and third-party risks at £70 per year each	0·56d.
Total working expenses	8·69d.

Taking, then, 8·69d., or even 9d., per motor-'bus mile as the total working expenses of motor omnibuses, there should be a profit per 'bus mile of 3·7d., even on the receipts of the present company and its very slow service and old stock. With, say, 50 single journeys per day of the mean length of 1·78 miles, instead of the present average of 30 single journeys (about) of car and 'bus, and with, say, 16 omnibuses running, the profits per day would reach at least £20 per day, assuming that the travelling public in Oxford require so much travelling facility, and it will, no doubt, fully support at least 30 per cent. more than is at present provided. This is £140 per week, or £7,300 per year, after charging every cost to revenue, including a depreciation rate which provides for the entire renewal of the 'buses every five years, and thus leaves a profit of about 35 per cent. on the capital outlay of, say, £20,000. To this expenditure, however, has to be added the cost of acquisition of the existing tramways and some expenditure in a few places in improving the road and street surface where not good and where too much arched or hog-backed. This work, however, is equally desirable for every other kind of traffic. With regard to the fares to be charged, I am of opinion that these should be the same as those now charged, the passengers getting all the advantages of better service and more comfortable vehicles without extra charge for the same distances. The service from Carfax to the station should be extended about half a mile, and the fare remain the same as now. On such extensions and new lines of service as may be found desirable by experiment, the fares should, I think, remain at 1d. per mile or thereabouts more or less as at present.

(Signed) W. Worby Beaumont.

On Aug. 25 Mr. Beaumont wrote to the town clerk as under:

Dear Sir,—I send herewith the statement *re* estimates of motor-omnibus service and the results of examination of the returns of the tramway company for 1904. With regard to the amount deducted for interest and sinking fund, please note that this at 6 per cent. is with reference to the motor omnibuses an improper charge, and should be very much less than 6 per cent., because the costs of working of the motor omnibuses, as given in my estimate, include a depreciation already of 20 per cent. charged against revenue, in addition to maintenance charges. A large part of the £1,200 deducted from this is therefore irrelevant. Will you please say that the number of miles run by the existing system was, as pointed out by Dr. Cannan, much larger than I had estimated, and this very largely reduces the receipts per car mile as compared with the receipts I had assumed. This, of course, materially alters the difference between receipts and costs, as will be seen in the statement sent you.—I am, faithfully yours,

W. Worby Beaumont.

STIRLING ELECTRICITY ACCOUNTS.

The accounts of the Stirling electricity department for the year ended May 15, 1905, show a total expenditure on capital account to that date of £39,050. Abstracts of the revenue account, balance-sheet, etc., are appended.

Revenue Account.

Dr. Expenditure.	£	s.	d.
To generation of electricity	1,422	4	10
Distribution of electricity	79	5	11
Attending and repairs to public lamps	239	1	4
Rents, rates, and taxes	69	0	10
Management expenses, salaries, etc.	379	6	0
Special charges, insurance, etc.	53	2	6
	2,242	1	5
Amount carried to net revenue account	1,904	19	2
	£4,147	0	7

Cr. Income.	£	s.	d.
By sale of current to private consumers by meter	2,634	3	0
Ditto for public lighting	1,372	5	0
Rental of meters and other apparatus	46	12	5
Rental of motor apparatus	64	0	2
Rents received	30	0	0
	£4,147	0	7

General Balance-Sheet.

Dr. Liabilities.	£	s.	d.
Capital account—amount received	39,000	0	0
	£39,000	0	0

Cr. Assets.	£	s.	d.
Capital account—amount expended for works	38,518	8	0

TRADE NOTICES AND NOVELTIES.

Motor-Driven Air-Compressors.

We illustrate herewith some of the latest designs of air-compressors introduced by Messrs. Reavell and Co., Limited, Ranelagh Works, Ipswich. The special feature in these machines is that they are arranged for direct coupling to electric motors without the intervention of any gears and with only two bearings in the compressor and motor complete. In

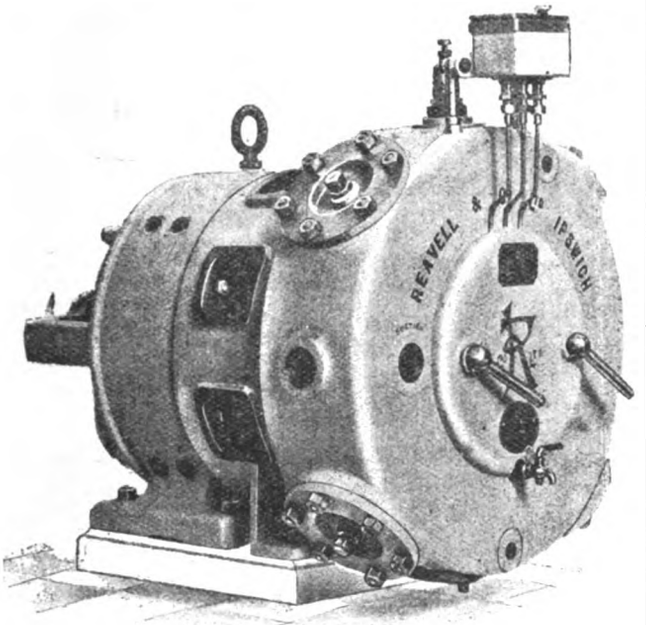

FIG. 1. Single-Ended Direct-Coupled Motor-Driven Compressor.

the machine shown in Fig. 1 the compressor shaft is passed directly through the armature of the motor into the motor outer bearing. A standard motor of the slow-speed type can therefore be used by omitting one end cover with its bearing and employing the studs for securing the bearing to attach the compressor to the motor. The compressor facing is spigoted so as to fit perfectly centrally in the field-magnet casting of the motor. The same construction is shown in section for double-ended machines (Fig. 2), which illustrates a polyphase motor-compressor combination similar to one of 80 h.p. included in Messrs. Reavell's exhibit at Liége. Referring to the illustration, it will be seen that this construction provides for the two compressor shafts being fixed directly into the spider of the rotor, while the through bolt, which is shown, enables the halves of the compressor shafts to be pulled up directly against the faces on the rotor. This illustration also shows how the compressor is directly bolted to the faces of the stator of the motor. An ordinary slow-speed motor of the alternating or direct current type can by this arrangement be directly coupled to the compressor. Another point of interest is that there is no need to provide a flywheel with this type of

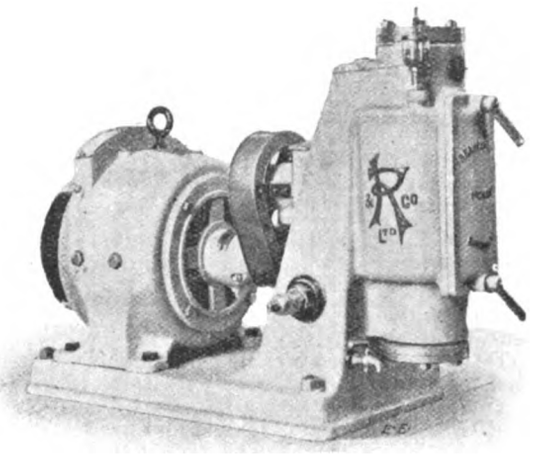

FIG. 3.—Motor-Driven Duplex Air-Compressor.

compressor, because the torque is almost perfectly regular. Fig. 3 illustrates the smaller duplex compressors which the makers have supplied in such large numbers to central stations

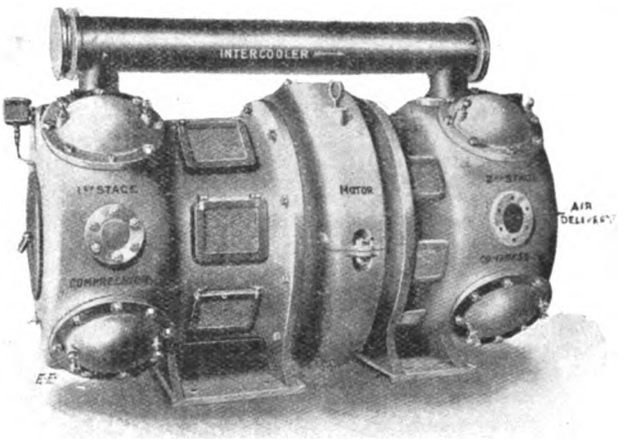

FIG. 4.—Two-Stage Motor-Driven Air-Compressor with Inter-Cooler.

and sub-stations for cleaning purposes. A portable type is also made. The latest design of the firm's two-stage compressor is illustrated in Fig. 4. Similar machines are in use in central stations in London and elsewhere, we understand, for supplying compressed air at high pressure for air-lift purposes. The design is of great interest to electrical firms who are interested

Section through Cylinders 45° to vertical.

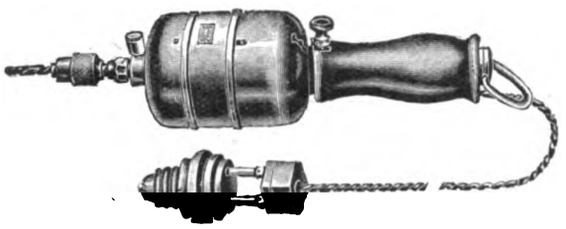
FIG. 2.—Section of Direct-Coupled Air-Compressor with Polyphase Motor.

Digitized by Google

in the introduction of electricity into collieries, as it provides a means of supplying the pneumatic coal-cutting tools at the face with compressed air and at the same time to take advantage of the saving to be effected by using electrical energy for driving the compressors, the latter being placed "in bye." This arrangement, by virtue of the high economy of the turbo-generators or steam dynamos which are used for the production of the electrical energy on bank, and also on account of the high efficiency of electrical transmission, naturally enables the energy to be delivered to the motor on the compressor at a low price and avoids the losses due to leakage and pipe friction which are observed in older systems where the compressed air is all obtained from large compressors installed on bank.

W.B. Novelties.

The 1905 novelty list issued by Messrs. Wallach Bros., 57, Gracechurch-street, E.C., includes some electric drilling machines of exceedingly handy patterns. Type L can be supplied with or without wheel gearing, as illustrated herewith. This type is especially suitable for bicycle dealers and repairers, engineers' and mechanical workshops. It is supplied for different rates of speed according to the diameter of hole to be drilled. Minimum weight is obtained by casing the motor with aluminium alloy. This casing, being fastened with bayonet locks, is readily removable, and so permits easy access to the brushes, lubricators, and bearings. Several other useful types



W.B. Type L. Electric Drill without Wheel Gearing.

W.B. Type L. Electric Drill with Wheel Gearing.

are dealt with, also a variety of apparatus, such as machinists' vices, central gear grinders, hot blast melting furnaces, combination brazers and forges, illuminators, portable heaters, etc.

A New Fitting Connector.

The weak point of many electric lighting installations is the connection between the wiring and the fittings. Unfortunately, also, this fact is aggravated by the construction of some of the higher classes of fittings, and by the conditions laid down by the best decorators and architects. For instance, in a room where the artistic decorations are such that no wood blocks can be used on the walls, the fittings have to be supported directly against the draping material used to cover the walls. In such cases a joint has to be made in a very confined space and afterwards covered by the metal base of the fitting. In consequence the joint is made under most difficult conditions, and in a position where it is likely to meet with the maximum ill-treatment and to do a considerable amount of damage in the event of a short-circuit. Messrs. J. J. Smith and Co. have just put upon the market the new connector which we illustrate herewith, which

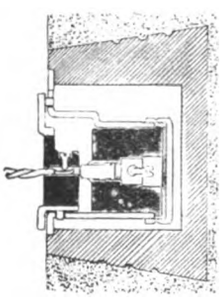


Fig. 1.

will not only render all joints behind the fitting unnecessary, but will also enable fittings to be easily removed for cleaning, or to be replaced by others. With this connector the mechanical support is obtained at the same time as the two electrical connections. As will be seen from Fig. 1, the wiring is led directly into the socket of the connector, which is sunk into a wood block, which in turn is cemented into the wall. The terminals (Fig. 2) for these wires are of ample size so that the looping-in system can be used, which avoids the necessity for any joints in the wires. The other part of the connector, which is attached to the fitting itself, has a projection which engages in the socket, and thus ensures that it can only be introduced in one position. Besides this guiding projection, which goes into the slot on the upper part of the connector face, there are two side pins which engage in the bayonet slots seen in the illustration. These form the mechanical lock as the pins slide down, the bayonet slots holding the fitting firmly against the connector, while the weight of the fitting is taken by the bottom surface of the projection. In its lowest position there is also a small screw, which can be seen on the left-hand side of Fig. 1, which engages in a hole in the socket and forms a further mechanical lock. The electrical connections are made between flexible contacts in exactly the same way as the connections in any lampholder.

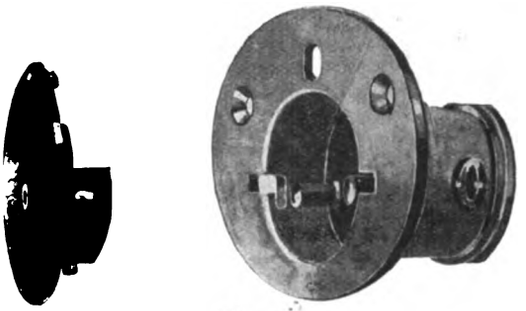

Fig. 2.

The wiring from the fitting terminates in substantial terminals, which are amply insulated. The whole device gives an excellent mechanical support, a good electrical connection, and its convenience will be as much appreciated by a householder as by electrical engineers of all classes. It reduces the fire risk from joints which can hardly be effectively protected, and at the same time renders the wiring of the building more complete. This connector can be seen at the showrooms of Messrs. J. J. Smith and Co., at 46A, Holborn Viaduct, which are well worth a visit by anyone needing high-class fittings.

Catalogues, etc., Received.

Cable Grip.—Messrs. Siemens Bros. and Co., Limited, have sent us a postcard illustrating their cable grip. This grip is fitted with a swivel and patent detachable link, and should be found of great use in drawing cables through pipes or conduits. The stock size is suitable for cables up to 2½in. diameter, but larger sizes can be supplied, we understand, at short notice.

Regulating Resistances.—The latest sheet from Messrs. Ernest F. Moy, Limited, deals with their shunt-regulating resistances type No. 92. The resistance frame is fitted with a nine-point switch connected to eight of the firm's standard resistance units mounted in a cast-iron frame, which is fitted with a perforated steel front and left open at the back for ventilation. The regulating switch is mounted on enamelled slate and fitted with a polished fibre knob.

PERSONAL.

The Colchester Town Council have granted £300 to the borough engineer, Mr. H. Goodyear; £150 to the electrical engineer, Mr. A. R. Siller; and £50 to the town clerk, Mr. H. C. Wanklyn, for their extra and special services in connection with the provisional orders authorising the tramways and intended extensions, the preparation of schemes, and the carrying out of the works of construction.

Mr. Ernest S. Colley has been appointed shift engineer to the Battersea Borough Council's electricity works at a salary of £104 per annum.

The Electricity Committee of the Southport Town Council recommend that the salary of Mr. A. S. Black, the assistant electrical engineer, be advanced from £200 to £225, rising next year to a maximum of £250, on condition that he gives an undertaking to remain with the Corporation for a period of three years.

The Electric Light Committee of the Coventry City Council decided on Monday to recommend the Council to increase the salary of Mr. J. A. Jeckell, manager of the electricity department, from £400 to £450 per annum. Some time ago it was proposed to raise Mr. Jeckell's salary, but at that time it met with a certain amount of opposition, the contention being that it would be better to wait until the results of the year's trading were known. It was, however, generally felt that Mr. Jeckell was entitled to some advance in view of what he had accomplished in converting a losing concern into a profitable one.

Prior to taking up his new duties as chief engineer at West Bromwich, Mr. W. A. Jackson, installation inspector of the Manchester Corporation electricity department, has been the recipient of a silver tea service, Mr. S. L. Pearce, chief engineer, making the presentation. Mr. L. H. Marlor, formerly assistant inspector, has been appointed Mr. Jackson's successor, with Mr. W. West as assistant.

LEGAL INTELLIGENCE.

ELECTRICAL CARS AND ACCUMULATORS.

Under a compulsory winding-up order made against the Garcin-Renault Electric Cars and Accumulators, Limited, accounts have been filed showing liabilities £4,777 against assets £265, and a deficiency to the shareholders of £4,575.

THEFT FROM TELEPHONE BOX.

At Stratford Police Court on Tuesday, Frederick Johns was charged with breaking an automatic telephone box and stealing 9s. 1d., the property of the National Telephone Company. On Monday afternoon Detectives Matthew and Clifton were looking out of the window in the police office at the Royal Albert Docks, when they saw the prisoner in a railway truck close by. They went to him and found that he had a telephone cash box in his hand. It was afterwards found that the public telephone, which is situated but five yards from the police office, had been greatly damaged and the cash box stolen from it. The prisoner now pleaded "Guilty" to the charge, and it was stated by Mr. F. F. Macnaghten, who prosecuted, that during the past few weeks no fewer than 70 public telephones had been damaged in this way. The prisoner was sent to gaol for two months.

COMPANIES' MEETINGS AND REPORTS

KALGOORLIE ELECTRIC TRAMWAYS.

A joint meeting of the holders of the A and B debenture stock was held on Tuesday to consider a resolution to authorise the directors to enter into a supplemental trust deed with the Consolidated Trust, the trustees for the debenture stockholders, consequent on this Company having made an agreement for the working of their tramways with the Kalgoorlie Electric Power and Lighting Corporation.

Mr. ALLEN H. P. STONEHAM, who presided, stated that the agreement was the outcome of very protracted negotiations between the two companies, and the Board believed that the result of it would be of great benefit to both concerns. At the time of their last annual meeting they had determined, owing to their negotiations with the Power Corporation having fallen through, to put up their own power-house, but he was happy to say that shortly after that meeting the negotiations were resumed, and the present working arrangement was made. Things moved very quickly in Kalgoorlie, and a price which was a fair one three years ago had proved to be exorbitant to-day. The old contract had, therefore, been terminated, and the new arrangement was based on this Company being supplied with power at cost, the Power Corporation to have a percentage of the net profits earned by the tramways over £20,000 per annum. The tramways were doing so well that he had every expectation that there would be a considerable profit for the Power Corporation at the close of the present financial year.

The resolution having been unanimously adopted by the holders of the A debenture stock, it was then submitted to the B debenture holders, when a shareholder inquired in what way the new deed would affect the position of the debenture stockholders. The Chairman replied that the agreement would result in larger profits for the Company, and so the margin, after providing for the debenture interest and the sinking fund, would be greater. The shareholder stated that what he particularly wanted to know was if the Power Corporation were to be given any prior charge over the debenture stockholders. The Chairman said they were not.

The resolution was then unanimously carried.

LIENS REGISTERED.

N.S. Electric Storage Co., Limited (London). — Issue on Aug. 10 of £1,800 debentures, part of a series created same date to secure £20,000. Charged on the company's undertaking and property, present and future. No trustees. No previous issue of same series.

Bolckow, Vaughan, and Co., Limited.—Issue on Aug. 30 of £26,700 debentures, part of a series created by resolutions of Feb. 23 and March 20, 1905, to secure £1,000,000. Property charged: the company's undertaking and real and personal property, present and future. No trustees. Total amount previously issued of same series, £180,700.

Newcastle and District Electric Lighting Co., Limited. — A trust deed, dated Aug 8, 1905 to secure £150,000 debenture stock, created by resolution of June 2, 1905, has been registered. Property charged: freehold land and generating stations at the Close, Newcastle-on-Tyne, and at Lemington; leasehold land and generating station at Forth Banks, Newcastle-on-Tyne, any money resulting from compulsory sale under any contract prior to date of trust deed or under any provisional order or Act of Parliament, and the company's general assets, present and future, excluding uncalled capital. Trustees: W. Milburn, 130, Fenchurch-street, E.C.; E Waterhouse, 3, Frederick's-place, Old Jewry, E.C.; and W. Greenwell, 2, Finch-lane, E C.

Paris.—The Waterworks Department of the Municipality require tenders for supply and erection of motors, pumps, and generators for the proposed waterworks at Chantilly. For particulars apply to above authority. Tenders by Oct. 12.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Florianopolis (Brazil).—The Municipality require tenders for the lighting of the town by Oct. 2.

Plasencia (Spain).—The municipal authorities require tenders for an electric lighting installation. Tenders by Sept. 15.

Olympia 1905 Exhibition.—The Executive Committee invite tenders for the loan or hire of 300-kw. direct coupled steam set.

Pontypridd.—The Urban District Council invite tenders for (Section B) overhead equipment for tramways; (C) cables for tramways. Tenders by noon on Sept. 30. See advertisement in last issue.

Bishop's Stortford.—The Urban District Council invite tenders for lighting such of the public streets as are at present lighted, for two or three years from Sept. 30. Tenders by 4 p.m. on Sept. 25.

Burton-upon-Trent.—The Corporation invite tenders for the supply and laying of feeder cables, conduits, and other works in connection therewith. Tenders by noon on Sept. 25. See advertisement in last issue.

Alicante (Spain).—The Harbour Board (Junta des Obras del Puerto) require tenders for two electric cranes, capable of lifting 10 000 ko. and 1,500 ko. respectively. Tenders by Sept. 15. Estimate, 107,010·10 pesetas.

Pembroke (Ireland).—The U.D.C. invite tenders for electricity supply mains, arc lamps and pillars, house meters, and switchboard panels. Tenders to Mr. J. C. Manly, Town Hall, Ball's Bridge, Co. Dublin, by 10.30 a.m. on Sept. 22.

Stalybridge.—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery, and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

Dublin.—The Lighting Committee invite tenders for the supply of (*a*) sub station switchboards, transformers, etc.; (*b*) extra high-tension and low-tension mains. Tenders to Chairman of the Lighting Committee, 3, Cork-hill, Dublin, by Sept. 18. See advertisement in last issue.

Langho (near Blackburn).—The Chorlton and Manchester Joint Asylum Committee invite tenders for the supply and fixing of the necessary telephones and electric bells at the new colony for epileptics at Langho, near Blackburn. Tenders to the Clerk, Chorlton Union Offices, All Saints', Manchester, by Oct. 3.

London County Council.—The London County Council invites tenders for the manufacture and laying of (*a*) 56 miles low-tension lead-covered, paper-insulated cables 20 miles dry-core telephone cables, cast-iron feeder pillars, etc.; (*b*) 24 miles extra high-tension three-core, lead-covered, paper-insulated cables, etc. Tenders to Mr. G. L. Gomme clerk, by 10 a.m. on Oct. 3. See advertisement.

Linlithgow (Scotland).—The Uphall and Broxburn District Lighting Committee invite tenders for the supply and erection of one suction gas-producer plant of 80 b.h.p. capacity; one 80-b.h.p. gas-engine; one 52-kw. dynamo; one automatically-reversing motor booster, two 280-ampere-hour storage batteries, switchboard, cables, meters, etc. Tenders to Mr. J. G. B. Henderson, county clerk, Linlithgow, by 12 noon on 18th inst.

London, S.W.—The London County Council invite tenders for the manufacture, supply, and delivery of 34 steel single-deck tramcar bodies; maximum traction swing bolster trucks for 34 electric cars; complete electrical equipments for 34 cars; or, alternatively, 34 steel single-deck cars, with trucks and equipments complete. Tenders by 10 a.m. on 29th inst.

Erdington.—Tenders are required for the construction of Section No. 1 of the Erdington tramways, comprising the laying of the permanent way, including copper bonding, wood block paving, and other works incidental to the laying of about 2½ miles of double-track tramway, for the Tramway Committee. Tenders to the joint engineers, Mr. Robert Green (of Messrs. Pritchard, Green, and Co.), of 37, Waterloo-street, Birmingham, and Mr. Herbert H. Humphries, engineer to the Council, Public Hall, Erdington.

Municipal Board of Mussoorie (India).—The Municipal Board invite tenders for the supply, delivery, and erection at sites, in complete working order, of the following plant: (*a*) steel power pipes; (*b*) water-motors; (*c*) alternators with exciters; (*d*) switchboards with instruments and apparatus; (*e*) transformers; (*f*) induction motors; (*g*) pumps; (*h*) workshop machines. Also for the supply and delivery of the following: (*a*) bare copper wire for overhead mains; (*b*) insulators and lightning arresters; (*c*) arc and incandescent lamps; (*d*) telephone equipment; (*e*) workshop tools; (*f*) general stores. Specifications, form of tender, and general conditions can be obtained on application to Mr. C. H. Shanan, municipal electrical engineer, Municipal Office, Mussoorie, India (telegraphic address, Shanan, Mussoorie), on payment of a deposit of Rs.75 (£5), which amount will be returned on receipt of a bona fide tender. Tenders by Oct. 23.

RESULTS OF TENDERS.

Brighton.—The Town Council have decided to purchase a coal-handling equipment for the Southwick power station from the Transporter Co., 7, Great Winchester street, E.C., at a cost of £2 321.

Warrington.—The Town Council have accepted the tender of Johnson and Phillips, at £564, for the supply of cables; and that of Hadfield's Limited, of Sheffield, at £614. 9s., for the supply of junction and curves for Rylands-street

N.E.R. Stoker.—Messrs. Meldrum Bros., of Timperley, have received an order from Babcock and Wilcox for one of their mechanical stokers to consume a mixture of slack and locomotive smoke-box refuse under a large Babcock boiler to be installed at Gateshead-on-Tyne for the North-Eastern Railway Co.

Digitized by Google

BUSINESS NOTES.

TRACTION.

Bournemouth.—A large public meeting last week pronounced in favour of Sunday trams.

Erith.—The Council having received several applications for season tickets, the matter is receiving the attention of the Tramways Committee.

Nottingham.—The Corporation have decided to extend the tramways so as to provide for the eastern district, the cost being estimated at £57,000.

Perth.—The municipal accounts for the year ended May 15 show that the revenue from the tramways amounted to £4,422, there being a deficit of £1,319.

Heywood.—The agreement arrived at between sub-committees of Heywood and Rochdale for the working of the trams has been approved by the latter Corporation.

Penmaenmawr.—The Urban District Council have decided to consider a scheme for an electric tramway up the Penmaenmawr Mountain at an approximate cost of £10,000.

Belfast.—It is probable that a compromise will be arrived at between the Corporation and the National Telephone Co. regarding overhead wires, to which we have referred in previous issues.

Leith.—At a meeting of the Town Council a proposal that the scheme of fares be remitted to committee for further consideration was rejected, and the action of the committee in conferring ½d. fares to Leith-walk was confirmed.

Woolton.—The Tramways Committee of the Liverpool Corporation have decided that they cannot recommend that the travelling facilities to Woolton should be increased by a motor 'bus service, as requested by the Rural District Council.

Bradford.—Application is to be made to the Board of Trade for sanction to borrow £30,079 for the construction of tramways at **Wyke.** After some discussion it was decided to refer the employés' application for an annual holiday to committee.

Weston, Cleveland, and Portishead Light Railway.—Mr. Justice Lawrence granted the company, on the 6th inst., a continuance for a week of the interim injunction restraining the Urban District Council from pulling up the rails connected with the plaintiff's line.

Darlington.—The receipts from the trams for the month of July as compared with last year showed that, although 51,019 more passengers had been carried, the receipts were £30. 2s. 11d. less, that 192·4 less miles had been run by the cars, and that the revenue per car mile was 1·6d. less.

North Staffordshire Light Railway.—The Light Railway Commissioners have submitted to the Board of Trade for confirmation under the Light Railways Act, 1896, an order made by them authorising the working of certain branch lines of the North Staffordshire Railway as light railways.

London United Tramways Co.—The work of erecting the trolley poles in Kingston has been proceeded with very rapidly during the last few days. Plans for the sub-station are before the Corporation. A number of residents in the neighbourhood of Richmond are petitioning for a line to Ham.

Halifax.—At last week's meeting of the Town Council a proposition was submitted for the doubling of the tramlines from Hall End to Bedford-street at an estimated cost of £1 425. This was agreed to, as also was a proposal that a double line of tramway be laid from Gibbet-street along Thrum Hall-lane, at an estimated cost of £1,250.

Bolton.—The accounts for the year ended March 31 show that the income from the Corporation cars amounted to £95 766, and the working expenses to £55,202, leaving a balance of £40 564. Interest and sinking fund charges absorb £13 014 and £12,278 respectively, £11,599 is carried to reserve, and £3,941 is contributed to the relief of rates.

Caversham.—At the meeting of the Urban District Council the clerk reported that he had received a letter from the town clerk of Reading stating that the Tramways Committee of the Reading Town Council would be prepared to confer with representatives from the Caversham Council as to the proposal for the extension of the tramway into Caversham.

Wellington (N.Z.).—The returns of the electric tramways during the year ended March 31, 1905 show that the receipts from passenger fares were £36,534, from mails £163, and from repayments £8, making a total of £36,705. The working expenses were £27,643, and the interest paid on loans £9 625, giving a total of £37,268. The Municipal Council has, therefore, to face a small deficiency of £563.

Yardley.—At the meeting of the Urban District Council the following proposition was rejected by 10 votes to 2, as implying a reflection upon the Tramways Committee: "That an official letter be sent on behalf of the Council to the company, asking them definitely whether they intend to lay down the tramway to Shirley, and, further, when they intend to commence laying down the tramway to Acock's Green and Olton."

Burnley.—Considerable discussion ensued at the meeting of the Town Council in regard to the allocation of duties. It was proposed to give their new electrical engineer the control of the tramway repair shops in addition to the overhead equipment, but finally it was decided to adhere to the old arrangement. An excellent suggestion that the electrical engineer should have charge of the electric equipment of the cars received little support.

Longton.—At the meeting of the Town Council the plan of the proposed light railway in Anchor-road to Sandford Hill, as submitted by the Potteries Electric Traction Co., was approved, and the company were recommended to construct a long loop in Anchor-road, near to Market-street, which might be utilised for special cars running on Saturdays during the football season, in order to avoid the overcrowding of the Market-place.

Rating of Trams.—At the meeting of the General Purposes Committee, Gillingham (Kent) Town Council a letter from the town clerk of Wakefield was read with respect to the rating of light railways and tramways, giving a list of those corporations and urban district councils which had agreed to contribute towards the cost of the special case to be submitted to the High Court. It was recommended that the Council contribute a sum not exceeding £10 towards the cost.

Bradford-Dewsbury.—A proposal has been made to the Bradford Corporation by the company operating the Dewsbury tramways that a through tramway fare should be agreed upon for the journey by tramway between Dewsbury and Bradford. The matter has been brought before the Bradford Tramways Committee, who have given authority for negotiations with the company, on the basis of the fares received being divided in proportion to the respective route lengths of the two lines.

Birkenhead.—At the meeting of the Town Council a question was asked respecting the issue of the through tram and ferry tickets on the Higher Tranmere route. In reply, it was stated that the number of tickets issued during August was 5,723, which represented a percentage of 9 28, as compared with 4·43 in July. The chairman of the Tramways Committee added that the traffic was improving steadily, and he thought the figures rather pointed to the necessity of trying the same experiment on the other tracks.

London County Council.—In connection with the reconstruction of the existing tramways along the Theobald's-road for electrical traction, the Works and General Purposes Committee of the Holborn Borough Council recommend that the County Council be asked to meet the wishes of the Benchers of Gray's Inn—viz., that silent road paving be laid down outside the Benchers' offices—seeing that that body made a handsome concession to the public by the improvement of that thoroughfare in the neighbourhood of their garden.

Sydney.—An experiment is to be made on the city cars with the Raworth system of regenerative control. So prevalent has become the practice of standing up in the cars that the following regulation has been adopted: "No person, other than an employé of the Commissioners, shall stand on any platform or other part of a carriage when a seat is available, and any such person who continues to so stand after being requested by the conductor or other authorised officer to be seated shall be liable to a penalty not exceeding £2."

Macclesfield.—At the meeting of the Electricity Committee a letter was read from Messrs. Newton, Son, and Bayley, engineers, as to the Cheshire tramway scheme. The letter asked for the support of the Council for an extension from Hazel Grove to Macclesfield, with a branch line connecting Handforth and Wilmslow. Some members of the committee considered that a more desirable scheme would be a light railway connecting Macclesfield with Knutsford, but it was decided to give the promoters an opportunity of appearing in person before the committee at its next meeting, and of explaining in detail their proposal.

Spen Valley.—At the meeting of the Cleckheaton Urban District Council on Tuesday a letter was read from the town clerk of Bradford stating that the Tramways Committee of his Corporation had had under discussion a proposal that a tramway should be laid from the top of Odsal to the city boundary at Oakenshaw. The Corporation was desirous of learning what the Cleckheaton Council would be prepared to do as regarded the construction of an extension line in their district, so as to afford through facilities between Bradford and the Spen Valley. The letter was referred to the General Purposes Committee.

Metropolitan Railway.—One of the new electric trains on the Metropolitan Railway met with an accident at Moorgate-street Station on Wednesday. It was completing its journey from the west, and was leaving the Circle line in order to run into an outer siding, when it missed the points and struck on the end of the intervening platform. Fortunately it was running slowly, but the force of the impact was sufficient to smash the compartment in which the driver stands, and he was seriously injured about the head and neck by broken glass. Two of the passengers in the train were taken to the hospital suffering from bruises and shock. The accident caused considerable delay to traffic.

Dover.—The profit made by the trams during the year ending March 31, 1905, amounts to £231. 10s. 8d., which is a great falling off compared with other years. In 1901, when the number of passengers carried was 2 710 420, the net profit amounted to £1,067. 14s. 6d.; in 1902, 2,905,823 passengers, profit £991. 12s. 6d.; 1903, 2 862,590 passengers, profit £1,025. 14s. 9d.; 1904, 2,871,332 passengers, profit £920 9s. 9d. The apparent drop in the profit this year, however, is to some extent explained by the fact that in addition to the ordinary repairs and renewals of equipment, several items of exceptional expenditure, amounting to £821. 17s. 4d., have been met out of the revenue of the year.

Worcester.—At the meeting of the Corporation the Streets Committee recommended the acceptance of the offer of the tramways company to extend their tramways along the Malvern road as far as the Brunswick Arms on terms set out by them in a letter of March 14. The terms were: to construct the line to the Brunswick Arms with rails laid on concrete, and a single line of setts placed lengthwise along each side of the rail, the remainder of the paving to be of macadam; the Council undertaking to maintain the track, leaving the company

Digitized by Google

responsible for the rails, etc., and offering to maintain the paving of the track for £20 per annum. After some discussion the matter was referred back. The Worcester Tramways Co. intend to apply to the Board of Trade for sanction to the transfer of the undertaking to the Worcester Electrical Traction Co. at the price of £6 500.

Sheffield-Rotherham.—A delay of 40 minutes' duration occurred on Tuesday to the through tramway traffic between Sheffield and Rotherham, owing to the breakage of an overhead wire. The service continues to be well patronised, the improved communication proving a distinct convenience. Later in the day Major Pringle, representing the Board of Trade, inspected the short length of newly-laid track necessary to connect the Rotherham and Sheffield systems. He journeyed from Rotherham by special car, being accompanied by Mr. Cross (electrical engineer and tramways manager), Mr. Jennings (borough surveyor), Mr. F. Renwick (assistant town clerk), and other officials. At Tinsley he was met by the Sheffield representatives, including Mr. Fearnley (tramways manager), Mr. Yerbury (electrical engineer), and Mr. Lancashire (deputy city surveyor).

Swansea.—At last week's meeting of the Tramways and Electric Lighting Committee, Mr. Sinclair presiding, a sub-committee was appointed to report upon matters relating to the working of the tramways—the allocation of the rentals to the tramways and the light railways, etc. A councillor raised the question of the fixed terms by which the Corporation were to get an extra 1 per cent. beyond the rentals. He inquired whether it was to come after payment of 6 per cent. dividend on the actual value of the company property, which he valued at £110,000, or upon the share capital of the company, estimated at £245,000? The latter would come to about £14,700 a year before the Corporation would be entitled to 1 per cent., whilst the latter would only mean £6 390. The chairman read the clause in the agreement, which was "upon the actual expenditure for the time being," and it was decided to include the point as one of the matters to be discussed by the sub-committee. The engineer is to report upon a proposal for a line to Foxhole and Pentreehwyth.

Colchester.—At the meeting of the Town Council it was reported that the Bill confirming the provisional order for the Military-road extension received the Royal assent, and it was decided that application be made to the Board of Trade for sanction to the borrowing of £7 334, the total estimated capital expenditure for carrying out the extension. It was resolved that school children be allowed to travel on the cars at half fares on Saturdays between 8 and 9.30 a.m. Mr. R. C. Bullough, the general manager and engineer, in his first annual report, gives some information supplementary to that contained in our last week's issue. The number of passengers was 2,801,085, being 70·02 times the population. Mr. Bullough estimates that during the months of August, September, and October last year at least 25 per cent. of the traffic was "novelty traffic," the loss of which will be felt in the ensuing year. To compensate in a measure for this loss, it will be necessary to curtail the number of early morning and up to noon cars during the coming winter. The working expenses per car mile show an economy as compared with several towns of a similar size.

Rhondda.—The contents of the report of the Board of Trade Commissioner with regard to the terms and provisions of the proposed agreement for the construction and working of the Rhondda tramways were made public at last Friday's meeting of the Urban District Council. The report was to the effect that the commissioner advised the Board to give its approval to the Council's scheme, subject to certain modifications and amendments, which the Council accepted. The commissioner accepted Sir Douglas Fox's figures as to the cost, which that gentleman estimated to amount to £258 000, which, after the deduction of a percentage in respect of depreciation, would mean a net amount of £193,875 at the end of 42 years, while the proposed rental of £2,250 per annum would amount to £196,035 in the period indicated. The commissioner, therefore, was of opinion that the Council's scheme was financially sound, subject to the insertion of a restrictive clause providing for increased rent in the event of expenditure on works of extension other than those contemplated by the present scheme being carried out. The commissioner also added that he had inspected the proposed route, and he was able to assure himself of the success of the scheme. Satisfaction having been expressed by members with the tenor of the report, the letter was then referred to the Legal and Parliamentary Committee to deal with.

Kirkcaldy.—Since the alteration of the tramway fares, about two months ago, when the halfpenny stages were very much shortened, there has been much dissatisfaction, and the receipts have considerably fallen. A meeting of the Tramway Committee of the Town Council was held last Friday night to review the situation. Mr. Francis, the burgh electrical engineer, submitted a report, which showed that the receipts for the past two months indicated a reduction at the rate of £1,800 per year, as compared with the same period of last year. On the other hand, they had been saving about £800 on working expenses, showing a net average loss at the rate of £1,000 a year as compared with last year. Mr. Francis suggested that instead of the present eight halfpenny stage scheme they should introduce a four halfpenny stage scheme. The only objection to a trial of this scheme was that in the event of it proving unsuccessful the fares would have to be raised, with possibly the same disastrous results as at present. The scheme, which he submitted, was on the principle of four halfpenny stages on the lower route and two halfpenny stages on the upper route, and that no reduction should be given to workmen. The committee approved of the scheme, but agreed that the workmen's fares should be continued, giving two halfpenny stages for a halfpenny. The matter will come up for decision at the meeting of the Council.

Dudley.—It is reported that at Tuesday's meeting of the Town Council it was decided, after considerable discussion, to refer the matters in dispute between the Corporation and the tramways company to arbitration. A letter was read from Mr. Garcke stating that the company had made every effort during the past few years to agree upon reasonable terms of settlement so as to avoid the unpleasantness, great expense, and other serious consequences to both sides of an arbitration, and it was with the greatest reluctance that they had decided that they were unable to accept the agreement as drafted on behalf of the Dudley Corporation. Ever since the tramways and light railways in the Dudley district had been under the control of the companies every effort had been made to carry on the business with a view to meeting the requirements of the public and the Dudley Corporation; and the town of Dudley had derived vast benefits during the past few years from the development of electric traction, while the average return on the capital invested had been only 4½ per cent. per annum. They thought, under these circumstances, it was a very great hardship on the companies that the Dudley Corporation should seek to impose upon them such terms as would effectually prevent the directors from carrying on the business with satisfaction to the public and the shareholders, and if the Corporation was determined to exact the proposed onerous and impossible terms from the companies to the full extent provided by the draft agreement, they had no alternative but to leave them the responsibility of having the matter decided by arbitration.

Dundee.—In the course of the debate upon the report presented by the tramways manager regarding the unfavourable position of Dundee as compared with Glasgow and other towns in respect of the percentage of operating expenses to receipts, Councillor Stevenson contended that the report missed the point, inasmuch as it did not show how the cost in Dundee could be reduced to the same point as in Glasgow. It was not enough to tell them that if the figures applicable to Glasgow were made to include charges for interest and depreciation, they would be in the same position as Dundee. If they had run as cheaply as Aberdeen, they would have saved £3,200 in 1904. He moved that the matter be remitted back for further consideration, so that they might arrive at the cause of the discrepancy between Dundee and many other towns. Councillor Brownlee, in reply said that when they considered that Mr. Richardson, the engineer, had brought down the coal consumption to such an extent that the cost was 1·881. per unit, they would see they could not go very much further in that direction. He contended that Dundee could not be compared with Aberdeen and Glasgow. These cities had no gradients like the Constitution-road of 1 in 11 up which to propel cars of 13 tons weight, and no lines which rose practically from sea-level to over 300ft., as they had in Dundee. The matter was remitted to the committee. The recent *plébiscite* upon Sunday running reversed the position caused by the first poll, and the new service was instituted last Sunday, when there was a big rush for the trams. The tramwaymen's association sent in an application for payment on Sundays at the time-and-a-half rate. During the discussion on this point a councillor proposed time and a quarter as a compromise, but finally the Council remitted the matter to committee.

Liverpool.—The foundation stone for the Corporation's new tramway offices in Hatton-garden was laid on Tuesday. The site is in a central position for dealing with the work of the department, and the plans which have been prepared by Mr. T. Shelmerdine, the Corporation architect and surveyor, suggest that a very handsome and commodious building will, in the course of the next year, be seen in Hatton-garden. The expansion of the tramway business rendered new offices imperative. Previously to the ceremony Sir Charles Petrie, chairman of the Tramways Committee, entertained a large number of councillors, officials, and others to lunch, and took the opportunity of reviewing the great progress made by the Corporation trams. The inscription on the foundation stone, which is of Swedish marble, is as follows: "City of Liverpool Tramway Offices. The Right Hon. John Lea, Lord Mayor. This foundation stone was laid Sept. 12, 1905, by Alderman Sir Charles Petrie, J.P., chairman of the Tramways Committee. Alderman Fred Smith, J.P., deputy-chairman; Councillor E. Lewis Lloyd, chairman of the Traffic Committee; Thomas Shelmerdine, Corporation architect and surveyor; Chas. R. Bellamy, C.E., general manager of tramways." The Lord Mayor was the recipient of a special souvenir of the occasion, which took the form of an 18-carat gold medal set with a large diamond of the finest water. At the meeting of the Corporation Sir Charles Petrie, in reply to a question, stated that the Tramways Committee had not yet considered the question of laying a tramline in Bootle to the north docks, but he would have much pleasure in bringing it before the committee. As to Cabbage-hall, they had now parliamentary powers to construct a line there, but before that could be done the Health Committee would have to widen the road. He added, in reply to a further question, that the Bootle Corporation would not allow them to lay the line unless they gave an undertaking that they would not carry anything but passengers on that particular line. The Tramways Committee could not see their way to do that, because under the Act of Parliament they had now got they were fully entitled to carry anything they liked over their lines.

LIGHTING AND GENERAL.

Wellington (N.Z.).—A large grain mart is to be erected, which will be equipped with electric hoists.

Wireless Station.—Mr. Marconi has opened a new station for wireless telegraphy service on Sable Island.

Paignton.—Sanction has been refused to the Town Council's application for a loan for an electric lighting scheme.

Hastings.—An inquiry has been held into the application of the Town Council for sanction to borrow £2,000 for electric lighting.

The Channel Islands.—The postal telegraph authorities have issued a statement that communication with the Channel Islands is restored.

Auckland (N.Z.).—The City Council have engaged Mr. W. Goodman to prepare a report relative to a combined electric light and dust destructor scheme.

Digitized by Google

Aldershot.—The Local Government Board has held an inquiry into the application of the Urban District Council for sanction to a loan of £2,000 for electrical purposes.

Whitby.—The Council's engineer has been empowered to make the necessary arrangements for holding an electrical exhibition in the Temperance Hall to open on the 29th inst.

Harrington (Cumberland).—The Urban District Council have received an application from Messrs. J. Bain and Co. regarding an electric lighting installation at their premises.

Irvine.—After a considerable discussion upon a tender of £6 646 from a London firm for an electric lighting installation, the Town Council referred the whole matter to committee.

Dewsbury.—At the meeting of the Town Council it was reported that sanction had been obtained from the Local Government Board to the borrowing of £9 762 for electric lighting purposes.

Removal.—Messrs. Hughes and Lancaster notify that their offices will be removed to-morrow from 47, Victoria-street, S.W., to 16, Victoria street, where all communications should be addressed.

Rostrevor.—A public meeting is to be held at an early date, at the instance of the local authority, in order to ascertain the wish of the inhabitants regarding a company's offer to instal electric lighting.

Battersea.—The Borough Council have decided to support the Poplar Borough Council in urging the London County Council to reinsert in their next General Powers Bill the clauses relating to wiring rejected by the Lords.

Dividends.—The debenture stock transfer register of the South Metropolitan Electric Light and Power Co. will be closed from the 20th to the 31st inst. for the purpose of preparing the warrants for the interest payable on Oct. 1, 1905.

Wells.—At the monthly meeting of the Town Council a notification was received from the General Post Office that the scheme for the extension of the telephone system to Wells, Shepton Mallet, and Glastonbury had received the sanction of the authorities.

Filter Papers.—Messrs. A. Gallenkamp and Co., 19 21, Sun-street, Finsbury-square, E.C., have just issued a pamphlet containing particulars of the various filter papers in connection with which they have the sole agency for the United Kingdom and the Colonies.

Poplar.—At a recent meeting of the Borough Council the Electricity Committee reported that they had under consideration the advisability of taking steps to secure the establishment of a public authority empowered to supply electrical energy in bulk to authorised distributors.

Halesowen.—At the meeting of the Oradley Parish Council it was reported that the Empire Electric Co. had intimated their intention of applying for a provisional order for electric lighting but that no understanding had yet been arrived at between the company and the Rural District Council.

Newfoundland.—The new cable connecting the Commercial Cable Co.'s Transatlantic system with the island of Newfoundland has been completed by the cable ship "Mackay Bennett," and is now open for business. This cable will be worked in connection with the Newfoundland Government telegraphs.

Northampton Institute.—From the prospectus for the ensuing session we observe that the various technical classes, including electrical engineering, will commence on Sept. 25 for evening pupils, and on Oct. 2 for day pupils. Some particulars relative to the institute's courses will appear in our next issue.

Humber Pilotage Commissioners.—At the monthly meeting of the Commissioners the Finance Committee recommended that notice be given to the Corporation to terminate the contracts for the telephone installations, and that terms be obtained from the National Telephone Co. for reinstalling their system. The resolution was unanimously adopted.

St. Helens.—The electrical engineer, Mr. Hollingsworth, has reported to the Electricity Committee a gross profit for the year of £2,003. The income of the department was £19,211. 2s. 5d., and the expenditure £17,798 0s. 11d. Out of the balance £500 has been placed to the credit of the plant and machinery account, and £100 to the accident fund, leaving a net profit of £1,403. 1s. 6d.

Manchester.—At the meeting of the Electricity Committee the chief engineer, Mr. S. L. Pearce, presented a report of the recent additions to plant which have been made at the various stations and sub-stations. A sum of about £40,000 have been spent in making the equipment equal to the city's requirements. Of this amount quite £13,000 has gone in improving and extending the street mains.

Swansea.—At the meeting of the Telephones Committee the manager reported that there were 1,104 subscribers, 1,249 instruments and working lines, and 177 orders in hand. It was decided to apply to the Postmaster-General for "free intercommunication" with the National Telephone Co.'s system. The manager said that intercommunication would probably be established in about 10 weeks' time.

Maidenhead.—The report for August of the resident engineer, Mr. C. O. Milton, notes an improvement of 2 per cent. in the load factor as compared with last year. An extension main to Ellington-road has been connected up. Twenty-seven additional public lamps have been erected. Applications for lighting have been received from residents in Taplow to the extent of 106 lamps, and it has been decided to lay the necessary mains.

Brixham (Devon).—Electricity has scored here. The Urban District Council offered a subsidy of £500 per annum for street illumination, and Edmundson's Electricity Corporation tendered a combined arc and incandescent scheme yielding 10,825 c.p., or an all-incandescent scheme yielding 10,425 c.p., which was accepted, as against the local gas company's offer to instal a system of Kern and self-intensifying burners.

Alloa.—At the monthly meeting of the Town Council the provost reported that negotiations had been reopened with the British Electric Plant Co. and the Town Council, and the result of these negotiations had been that the parties had practically adjusted matters in such a way that the Town Council would, when arrangements were completed, be in a position to supply electric current consumers at an exceedingly moderate flat rate, something like 4 d. per unit.

Stock Exchange.—The committee has ordered the following securities to be quoted in the official list: Rosario Electric Co.'s 12,000 6 per cent. cumulative preference shares of £5 each, fully paid, Nos. 1 to 12,000, and 8,000 6 per cent. cumulative preference shares of £5 each, £4 paid, Nos. 12,001 to 20,000; Daimler Motor Co.'s (1904) 62,276 ordinary shares of £1 each fully paid, Nos. 1 to 62,276, and 64,200 6 per cent. cumulative preference shares of £1 each, 10s. paid, Nos. 1 to 64,200.

Crewe.—At the meeting of the Electricity Committee a letter was read from the Local Government Board requesting to be furnished with plans of the proposed works and detailed estimates showing how the amount of £2 100 (for which application had been made for sanction to borrow for the purposes of the electric light undertaking) was made up. The Electrical Engineer stated that he was supplying the information asked by the Local Government Board. It has been decided to erect a lamp in Collins-street.

Southwick-on-Wear.—At the monthly meeting of the Urban District Council a letter was read from the County of Durham Electrical Power Distribution Co., submitting, in accordance with the Council's request, terms for the lighting of the public streets in the district by electricity. The Council will give the matter their consideration. The Council granted their consent to the application of the County of Durham Electric Power Supply Co. to the Board of Trade for consent to the laying of overhead high-tension and distributing mains.

Lye and Wollescote.—At the monthly meeting of the Urban District Council a letter was received from the Midland Electric Corporation offering a reduction in their flat rate of from 4½d. per Board of Trade unit to 3½d. in the case of prompt payment, and stating that in order that consumers might receive the discounts it would be necessary for the Council to give an assurance that they would not insist upon the discounts specified in their agreement with the company. The Council agreed to waive their claim to the discounts mentioned for five years.

Wigan.—The Corporation have approved the following recommendation of the Streets Lighting Sub-Committee: "Street lighting in Pemberton—Moved by the chairman, seconded by Mr. W. Wilson, and resolved that in the opinion of this committee the cost of lighting the Pemberton part of the borough is much in excess of what it ought to be, and they recommend that the lighting should be converted from electricity to gas, and the change made by easy stages." The committee estimated that by substituting gas for electric light there would be at least £500 a year saved.

Brazilian Electricity Co.—The recent reports regarding the sale of certain electric undertakings in Brazil are now confirmed by the announcement that the principal assets of the Brazilian Electricity Co. of Berlin have been disposed of. These are the telephone installation at Rio de Janeiro and the Villa Isabel tramway in the same city, which have been taken over (according to the Berlin *Tageblatt*) by the Brazilian Securities Co. It is stated that the purchase price yields a considerable profit to the Berlin company as compared with the book value of the undertakings.—*Financial Times.*

Hamilton (N.B.).—Under the auspices of Edmundson's Electricity Corporation, the lessees under the Hamilton Town Council Order for the supply of electricity to the town, an electrical exhibition has been opened in the town hall. The object of the exhibition is to acquaint those interested in the subject as to the current taken from the mains and supplied from the company's electricity works. At the opening ceremony Bailie Meechan (convener of the Electrical Committee of the Town Council) presided. Mr. Wigham, chief engineer for Edmundson's Co., gave an interesting address descriptive of the various exhibits in the hall.

Edinburgh.—The Parish Council have decided to appeal to the valuation court against the valuation of the Corporation electric light undertaking. Hitherto the system adopted by Mr. Hay, the burgh assessor, has been to assess on the average principle, taking account of buildings, plant, etc., but now he intends to assess on the profits principle, which this year would mean the difference between £6,000 and £12,000 in the rates. The Parish Council are to be represented in the court by counsel, and the Electric Lighting Committee have resolved to oppose to oppose the Council, and to employ counsel for that purpose.

Ayr.—At the meeting of the Town Council the report of Mr. R. Marshall, the electrical engineer, for the year to May 15 last was submitted. This showed that during the year about two miles of additional cable had been laid. The total number of consumers at the end of the year had been 885 as compared with 776 the previous year. The capital expenditure was £32 234 5s. 6d., an increase of £4 709. 5s. 5d. The total revenue had been £12 251. 2s. 4d., showing an increase of £393. 3s. 9d. on the previous year. The total working expenditure had been £6 447 17s. 10d., and the interest and sinking fund £4,910. 12s. 10d.—total, £11,358. 10s. 8d., thus leaving a net surplus of £892. 11s. 8d., as compared with a net surplus of £627. 15s. in the previous year. Dean of Guild Fraser moved that the charge to private consumers be reduced from 5d. to 4½d. Provost Allan moved as an amendment that the charge remain at 5d. The amendment was carried by nine votes to seven.

Digitized by Google

Pontardawe.—At last week's meeting of the Rural District Council a letter was received from the Brynamman and District Electric Lighting Supply Co., offering to light Brynamman, Gwaunceagurwen, and Cwmgorse, and the clerk was instructed to write and ask for terms per lamp. Councillor James wanted to know why terms were asked for from a private company when the Council had an electric lighting scheme for the whole of Swansea valley? Dr. Jones and Mr. Francis pointed out that the figures supplied would be very useful for the Council to compare with. The report of the electrical engineer on the Council lighting scheme is to be considered at the next meeting.

Faversham.—At last week's meeting the Town Council had before them the Electric Supply Sub-Committee's estimate of their expenditure for the next half-year. This showed a total of £1,095 for the six months, and credits amounting to £555, leaving £540 to be met from the district rate. It appeared that at the meeting of the sub-committee the deputy-mayor gave notice that at the next meeting he would propose that the gas-intensifying gas lamp be fixed, with a view, if the results were satisfactory, of substituting them for the electric arc lamps. Another member gave notice to bring forward the question of substituting some other description of electric lamp for the arc lamps.

Telegraph Facilities.—At the Liége conference of the Association of British Chambers of Commerce the following resolution was adopted: "That this association is of opinion that a continuous day and night and Sunday service, both for receipt and delivery of telegrams, should be established in all towns with over 50,000 inhabitants where such a service does not at present exist, and that the executive be desired to take what action they consider needful to bring about this improvement." Discussing telegraphic facilities and the opposition from many chambers of commerce to work on Sunday, the delegates declared that work on six days was enough, but they did not object to telegrams on Sunday in case of life or death.

London Gazette.—The partnership between George Septimus Hooker and Percy Stephen Harris, carrying on business as electrical and mechanical engineers at Paragon Works, Retreat-place, Hackney, London, has been dissolved by mutual consent. The first meeting in the estate of William Jefferson, electrical engineer, 3, Grainger-street, Darlington, will be held at the official receiver's offices, 8, Albert-road, Middlesbrough, on Sept. 22 at 12 30 p.m. Ernest Bowman Rawlinson, Halifax Commercial Bank-chambers, Bradford, has been appointed trustee in the estate of Albert John Harris, electrical engineer, Borough Mills, Bower-street, Bradford. David Sibbald, 23, St. James's-street, Derby, has been released from trusteeship in the estate of Benjamin George Hodges, electrical engineer, 21, St Luke-street, Derby.

Gomersal.—At a previous meeting of the Urban District Council Mr. Woodhouse, of Leeds, engineer to the Electrical Distribution of Yorkshire, had stated his company were desirous of obtaining a provisional electric lighting order for Gomersal and other districts, and requested the consent of the Council. At that time the matter was referred to the General Purposes Committee. A further communication stated that the company would be prepared to supply power for private lighting at 4d. per unit, and that they would give a guarantee to the Council that the charge for street-lighting should not exceed 2d. per unit. It was decided that before taking any action the Council should ask to be furnished with a plan showing which streets the cable was intended to go through, and any other necessary information.

Warrington.—At the monthly meeting of the Town Council the following letter, sanctioning a loan of £4,000 for electric lighting purposes, was read from the Local Government Board: "As regards the loan of £1,000, I am to state that, having regard to the time which has elapsed since the land was acquired, the Board have fixed a period of 53 years for the repayment of this loan in place of the usual period of 60 years. I am at the same time to state that if the Town Council intend to apply to the Board for sanction to any further loans to defray the cost of the acquisition of other portions of the land purchased from Fairclough, the application should be made at an early date, and should specify the purpose for which the land will be used. I am further to request that in any future case where it is proposed to acquire land by means of a loan, the Town Council will be careful to defer the completion of the purchase until the Board's sanction to the loan has been obtained."

Gas versus Electricity.—A conference of the Gas Managers' Institute of Wales and Monmouthshire was held at Cardiff last week. Mr. T. Canning, Newport, in his presidential address, said that, despite all opposition, their industry was more prosperous in this country than ever. While in 1882 there were only 500 gas undertakings in Great Britain, there were now 719 such undertakings, supplying 151,677,693 thousands of cubic feet to 4,351,125 consumers. The paid-up capital expended in these undertakings was £117,972,458. Their industry had undergone a transformation during the past 21 years. Costly improvements were introduced for cheapening the price of gas, and at the same time reducing consumption. The conflict with electricity was not over, but he had no fear of the issue if average energy was put forth by gas managers. Public lighting had more attention from electricians than private lighting, but electric lighting had failed to give satisfaction in the public streets.

Gillingham.—At the meeting of the Town Council it was reported that a memorial had been received from consumers in the borough asking the Council to reduce the price of electric light, and it was recommended that the Council reduce the price as follows: flat rate from 4½d. to 4¼d. per unit; maximum and minimum demand, from 7d. and 2d. to 7d. and 1¾d. per unit. It was also recommended that revised charges be made for street-lighting. The estimates for the half-year ending March 31, 1906, provide for a revenue of £6,706, and a net profit of £491 after allowing for capital charges. The engineer reported that the equivalent of 113 8-c.p. lamps had been connected to the mains since the last meeting, making a total of 45,496 8-c.p. lamps with 248 consumers connected; and that applications had been received for the equivalent of 394 8-c.p. lamps. The committee recommended that the four single-light standards in High-street, Old Brompton, be converted into three-light standards, and also that four single-light standards in Canterbury-street be converted into three-light standards. The recommendations of the committee were agreed to.

Dundee.—At the meeting of the Town Council a letter was submitted from Messrs. Gourlay Bros. and Co. with reference to the question of supplying energy for their shipyard. They stated that the committee recommended the Council to refuse to supply them with current at a penny rate, but would be willing to give them current on a sliding scale basis as drawn up by the electrical engineer. When this scale was designed it was never contemplated to apply it to such a large consumption of current as theirs would be, as was proved by the fact that the published scale only provided for a maximum demand of 50 kw., whereas they would need at least four times this for their shipyard only, and their intention was to introduce electricity also to their engine works as soon as they could make the necessary arrangements. As regarded the cost of laying the cable to their yard, they asked if it was not likely that it would very quickly tap other sources of supply. Mr. Charles Gourlay attended the meeting and made a statement supplementary to the letter. It was in March last that his firm decided to apply electricity to the driving of their shipyard machinery, and though they had not placed the contract for the generating power, they had selected their contractor. Mr. Richardson approached them with the view of getting them to take current from the Corporation, and as a result of a good deal of negotiation they were led to believe that the Corporation would favourably entertain the idea of giving the current at 1d. per unit. They had tried to reconcile themselves to a sliding scale, and, in case there should be any misunderstanding, he wished to state that they did not object altogether to a sliding scale basis. But they objected to a scale based on kilowatts. What they would agree to was a sliding scale on the amount of units used. He had in his possession telegrams from shipbuilders at other ports, and in no case was there a sliding scale, the charge varying from ¾d. to 1¼d. It was agreed to refer the question to committee, Messrs. Gourlay and Co. to give an idea of the quantity of energy they would take.

Dunfermline.—For some months correspondence relative to the electric lighting of Dunfermline has been proceeding between Provost Macbeth (on behalf of the Corporation) and Messrs. Bramwell and Harris, electrical engineers to the Fife Electric Power Co., whose generating station at Townhill was opened a week or two ago. The following are the heads of agreement proposed by the company: (1) The Fife Electric Power Co. to give a supply of electricity in bulk to the Corporation of Dunfermline at one point situated near the centre of the town. (2) The current to be transformed into continuous current by machinery supplied, maintained, and operated by and at the expense of the Fife Electric Power Co. The pressure of supply to be 460 volts, suitably arranged with the necessary balancers for use on a three-wire system at 230 volts each side. (3) The site and buildings for the necessary sub-station for containing the machinery before mentioned is to be provided by the Corporation, free of cost and free of rent to the company. (4) The price to be paid by the Corporation for the supply of current to be in accordance with the following scale for the first year during which a supply is taken, and to be ½d. less in each case on the same scale after the expiry of the first year—under 100,000 units per annum 1½d., 100,000 to 200,000 1¾d., 200,000 to 300,000 1¼d., 300,000 to 500,000 1⅛d., 500,000 to 750,000 1d., 750,000 to 1,000,000 ⅞d., 1,000,000 to 3,000,000 ¾d. (5) In the event of a coal strike occurring, or of any other unforeseen circumstances arising, which may make it impossible for the company to supply at the foregoing figures, these prices shall not be binding on the company, but such other prices as may be agreed between the parties, or, failing agreement, as may be determined by arbitration, shall be charged and paid instead thereof for such time as the increased cost of production shall exist. (6) This agreement to remain in force for five years, and to continue thereafter from year to year, subject to 12 months' notice being given by either party. Provost Macbeth replied to the effect that he did not think that the Corporation would be willing to enter into an agreement unless a clause were to be inserted to read that the Corporation as authorised distributors would supply all electricity in the burgh, the only exception being, say, the factories, where it would not be reasonable for them to expect to have a monopoly. As to the prices proposed under head 4, they, in his opinion, ought to be ½d. less, at least, from the commencement of the agreement. Clause 5 was an impossible clause. Messrs. Bramwell and Harris, in a subsequent communication, expressed their willingness to delete the words "or of any unforeseen circumstances arising," and to insert after the words "shall be charged and paid instead thereof" the words "not exceeding 2d. per unit." Alternatively, if the Council very much wished it, the engineers would be disposed to agree to the words "during the continuance of the strike," instead of "for such time as the increased cost of production shall exist." The whole matter will be discussed by the Town Council at an early date.

PROVISIONAL PATENTS, 1905.

SEPT. 4.

17814. **Improvements in apparatus for controlling or/and supplying current for power and light on consumers' premises during certain periods.** George Scobell Ellis and Alfred Mills Taylor, 12, Ashfield-road, King's Heath, Worcestershire.

17818. **Improvements in electric cable conduits.** William Higgins, 21, Villas-road, Plumstead, Woolwich.

Digitized by Google

17826. **Improvements in electric clock systems and the like.** Isaac Hardy Parsons and Alfred Ernest Joseph Ball, 40, St. Saviour's-road East, Leicester.

17835. **An improved form of electrical contact breaker.** Ernest Payne, 6, Cambridge-road, Hove, Brighton, Sussex.

17838. **An improved trolley head for electric tramways and railways.** Alfred Thorneycroft Eardley, Ericville, Woods Moor-lane, Stockport.

17842. **Improvements in and relating to wire-coating machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

17843. **Improvements in and relating to electric motors especially intended for hoisting and similar purposes, and in systems of control therefor.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

17873. **Improvements in signalling by electromagnetic waves.** Charles John Briggs, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

17878. **Improvements in insulators for current-carrying rails of electric traction systems.** Alfred Watkins, 322, High Holborn, London.

17881. **Improvements in electric securing devices for doors and the like.** Otto Roeseke, 6, Lord-street, Liverpool. (Complete specification.)

17888. **Improvements in combined electric switches and automatic circuit breakers.** John Henry Holmes, 47, Lincoln's-inn-fields, London.

SEPT. 5.

17896. **Improvements relating to electrical ignition systems for internal-combustion engines.** The Electric Ignition Company, Limited, and Frederick Harold Hall, 24, Temple-row, Birmingham.

17897. **An improved electrical generator system for use in connection with automobiles and the like.** The Electric Ignition Company, Limited, and Frederick Harold Hall, 24, Temple-row, Birmingham.

17955. **Improvements in electrical relays.** Carl Gustaf Roos and Charles Bernhard Roos, 55, Chancery-lane, London. (Complete specification.)

17956. **Improvements in or relating to direct-current electric motors.** William Phillips Thompson, 322, High Holborn, London. (Gustavus McAlpine, Mauritius.)

17957. **Improvements in step-by-step electric switches especially applicable as line selectors.** Isidore Bernard Birnbaum and Herbert George White, 322, High Holborn, London.

17974. **Improvements in joints for electric cables.** Siemens Bros. and Co., Limited, and Edwin Montague Allman Neale, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

SEPT. 6.

17990. **Railway automatic or electrical danger signal to be worked by a treadle or electric bar.** Joseph Isaiah James Lee, 12, Brent View-road, West Hendon, London.

17996. **A new or improved device for use in supporting electric cables, pipes, rods, or the like.** Frederick Mitchell and Francis Gunn, 3, Brown-street, Market-street, Manchester.

17997. **Improvements in or relating to electric insulators.** Thomas Cushing, care of Union of London and Smith's Bank, Croydon.

18006. **Improvements in and relating to electric fans and the like.** Reginald Page Wilson and Arthur Grotjan Marshall, 18, Southampton-buildings, Chancery-lane, London.

18013. **Improved means of rectifying alternating electric currents.** Frank Stewart Povah and Sydney George Livett, 9, Warwick-court, Gray's-inn, London. (Complete specification.)

18016. **Improvements in connectors for electric cables.** Ernest Charles Lea, 18, Fulham-place, Paddington, London.

18037. **Improvements in receivers for the wireless transmission of signals.** Valdemar Poulsen, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Sept. 17, 1904, being date of application in Denmark.) (Complete specification.)

18044. **Improvements relating to electric lamp holders** James Paterson, 18, Southampton-buildings, Chancery-lane, London.

18051. **Improvements in and connected with current takers or trolleys for overhead wires of electric railways and the like.** Otto Hoffmann, 6, Lord-street, Liverpool. (Date applied for under Patents Act, 1901, Sept. 9, 1904, being date of application in Germany.) (Complete specification.)

18053. **Improvements in brush-rocking gear for dynamos.** Henry Leitner and Richard Norman Lucas, 4, Stuart-street, Finsbury, London.

SEPT. 7.

13093A. **Improvements in or relating to electric drills.** Alfred Julius Boult, 111, Hatton-garden, London. (William Obed Duntley, United States.) (Date applied for under Rule 5 of the Patents Rules, 1905, June 24, 1905). (Complete specification.)

13093B. **Improvements in or relating to switches for electric drills.** Alfred Julius Boult, 111, Hatton-garden, London. (William Obed Duntley, United States). (Date applied for under Rule 5 of the Patents Rules, 1905, June 24, 1905) (Complete specification.)

18076. **Improvements in accident preventing or life-saving apparatus for electric tramcars and like vehicles.** Thomas Arthur Bennett, 3, Brown-street, Market-street, Manchester.

18089. **Installations of electrical clocks for public, domestic, and general use.** Edward Leslie Hunt, Queen's Hotel, Ballyconvarna, co. Clare, Ireland.

18102. **Improvements in transmitters for automatic telegraph systems and the like.** John Gell, 34, Castle-street, Liverpool. (Complete specification.)

18118. **Improvements in crossover points for the overhead electric conductors of trolley traction systems.** Arthur Henry Holmes and Henry Walter Holmes, 111, Hatton-garden, London.

18121. **An electric regulator for incubators and the like.** Alfred John Gaunt, 12, Baldwin-terrace, St. Peter-street, Islington, London.

18126. **Improvements in electric train control systems.** August Sundh, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

18144. **A thermo-electric generator.** Jules Lecoche, 42, Rue Sadi-Carnot, Armentières (Nord), France.

SEPT. 8.

18147. **Improvements in commutators for electric ignition of gases in internal-combustion engines.** George William Somerville and Oliver Hicks, 68, Owen-street, Accrington.

18148. **Improvement in self-propelled electrical motorcar or vehicle.** Louis Collender, Thornton House, Matlock.

18155 **Electromagnetic selective separator.** Selimo Romeo Bottone and Dirk Croese, 93, Manor-road, Wallington, Surrey.

18193. **Improvements in microphones or telephone transmitters.** Franz Treyer, 37, Essex-street, Strand, London. (Date applied for under Patents Act, 1901, Feb. 15, 1905, being date of application in Switzerland.) (Complete specification.)

18208. **Improved contrivance for truing the surfaces of commutators.** Edwin Barbridge Phillips and Thomas Cresswell Parkin, 22, Southampton-buildings, Chancery-lane, London.

18209. **Improvements in electric control systems and apparatus therefor.** Leonard Alexander Tirrill, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Sept. 8, 1904, being date of application in United States.) (Complete specification.)

SEPT. 9.

18264. **Improvements in gas or vapour electric lamps.** The firm W. C. Heraeus, 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Oct. 14, 1904, being date of application in Germany.) (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Sept. 28.

1904.

19326 **Electric hand switches for motor-cycles and other like purposes.** Janes.

19330. **Electrical systems of railway signalling.** British Thomson-Houston Company, Limited. (General Electric Company.)

20496. **Time-consuming mechanism for operating electric cut-outs and other devices.** Gardner.

20970. **Braking or stopping devices for electric motors.** Hultqvist.

21145. **Means for automatically compensating for changes in the voltage of electric circuits.** Leitner.

21211. **Method of regenerating negative accumulator plates of diminished capacity, or for avoiding the diminution in capacity of new plates.** Kieseritzky.

21903. **Electricity meters.** British Thomson-Houston Company, Limited, and Lloyd.

22157. **Dynamo-electric machines.** British Thomson-Houston Company, Limited. (General Electric Company.)

22246 **Distribution of electricity for electric traction.** Gibbs.

22818. **Systems of control for electrically-operated doors.** British Thomson-Houston Company, Limited. (General Electric Company.)

22819. **Alternating-current electric motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

22821. **Windings for alternating-current dynamo-electric machines.** British Thomson-Houston Company, Limited. (General Electric Company.)

23203. **Contacts for electric controllers, reversing switches, and the like.** British Thomson-Houston Company, Limited. (General Electric Company.)

23254. **Construction of trolley head for collecting electricity from electric trolley wires or the like.** Phillips.

23525. **Electrical radiators.** Dowsing.

23817. **Electric motor control systems.** British Thomson-Houston Company, Limited. (General Electric Company.)

NOTES.

Self-Contained Electrical Locomotive.—Mr. Hugh Reid, the managing director of the North British Locomotive Company, proposes to solve the problem of electrical locomotion by installing generating apparatus on the locomotive, so disposing of the difficulties of transmission and transformation. This is rather on the lines of Heilmann's experiment, except that Mr. Reid proposes to use a Parsons condensing turbine instead of a Willans high-speed engine. He proposes to employ an air-cooled condenser of novel design. Several locomotives on Heilmann's plan were used on the Western Railway of France without success.

Armstrong College.—The syllabus of Armstrong College (late Durham College of Science) exhibits the usual comprehensive courses in civil, mechanical, mining, naval, and electrical engineering. There is a three-year diploma course for electrical and other branches of engineering, and students are prepared for the degree of B.Sc. The laboratories are equipped with up-to-date apparatus on a large scale. Compound steam-engines are used to drive the dynamo which supplies current for lighting the college buildings. As is to be expected, the college has a strong marine and mining engineering side. The session commences on the 25th inst.

Institution of Engineers and Shipbuilders in Scotland.—The fifty-ninth session of this institution will be opened on the evening of Oct. 24 in the institution rooms, Bath-street, Glasgow, when the president, Mr. James Gilchrist, shipbuilder, will deliver an address, which will be followed by the reading of a paper on "The Determination of the Principal Dimensions of the Steam-Turbine, with special reference to Marine Work," by Mr. E. M. Speakman. On the evening of Nov. 10 there will be an exhibition of inventions and objects of interest appertaining to shipbuilding and engineering, which will be held within the St. Andrew's Hall, Charing Cross, Glasgow.

The Telephone Service.—It is understood that the Post Office and the National Telephone Company have entered into an arrangement for the mutual development of the two systems so as to prevent overlapping. For natural expansion certain areas have been allotted to each. A joint deputation of the Post Office and the company, including Mr. John Gavey, engineer-in-chief to the Post Office, and Mr. Gaine, the general manager of the company, is visiting the United States to study the system there, the American Government placing all facilities at their disposal. On returning the deputation will present a report to the Postmaster-General and the directors of the company, and if any improvements are considered desirable they will be introduced simultaneously on each system.

Municipal Telephones.—The Brighton Corporation recently applied to the Local Government Board for sanction to a loan of £11,617 in connection with their telephone undertaking. The Board have replied according the necessary permission in respect of £4,208 and £1,936 for expenditure already incurred, but in regard to the balance they inquire whether the Corporation have considered the question of entering into negotiations with the Postmaster-General with a view to the absorption of their undertaking. Accompanying the Board's reply is an extract from the parliamentary proceedings of the late session, in which Lord Stanley stated, in response to some remarks by Mr. John Burns, that he was quite ready to enter into negotiations with any of the telephone-owning municipalities. It will be remembered that Lord Stanley also implied in his later pronouncements that he now considered it a mistake to encourage municipal telephony. Having regard to the present position of matters in the telephone world, it will be of considerable interest to see what view the Brighton Corporation takes of the matter when it discusses it at an early date.

Large Static Transformers.—The Stanley Electric Company, U.S.A., have constructed for the Niagara Falls works of the Pittsburg Reduction Company a static transformer of record size. It is to be used for the manufacture of aluminium, for which electrical furnaces are employed, and in order to obtain high temperatures it is necessary to transform the current so that the amperage is exceedingly high and the voltage relatively low. The primary current has a frequency of 25 cycles at 2,200 volts. The secondary current is 80,000 amperes at 25 to 50 volts. The transformer occupies a floor space of 86½in. square. The height over all is 11ft. 6in., and the gross weight 50,000lb. The secondary winding consists of 12 coils of one turn each, arranged so that by means of heavy switches they can be connected all in parallel, the several combinations giving a secondary current of 80,000, 40,000, or 20,000 amperes, the voltage in each case varying in an inverse ratio to the current. The primary coils have a number of taps brought out at several points in the windings, which taps provide connection to a special oil-type regulator, enabling the secondary voltage to be varied in suitable steps from maximum to minimum. Although the transformer is rated at 2,000 kw., it can be run for long periods at 4,000 kw. without overheating.

Canadian Telephony.—We have received report No. 36 of the Select Committee appointed to enquire into the Canadian telephone system, which brings matters down to July 13. This report deals with the evidence given by Mr. A. L. Têtu and Mr. J. B. Ware, two experts from the United States, who have been associated with the independent telephony movement. The general effect of their testimony in regard to the competition between the Bell and the independent companies was that the apparatus installed by the latter was quite equal or superior to that of their rivals, and much cheaper. Mr. Têtu considered that Government ownership of the trunk lines would be premature, but he favoured legislative restrictions when granting franchises. Asked what he considered the best means of ensuring an ample and continuous long-distance service to Canadian independent telephone systems, the witness replied that the construction of independent long-distance lines should be encouraged, as in the United States. He stated that of late the Bell Company had made overtures to certain independent companies for inter-communication on trunk lines. Mr. Ware traced the history of the independent companies' growth, showing that they had often been successful in resisting the efforts of the Bell Company to oust them. He saw no reason why the operation of trunk lines by the Government should not be a success.

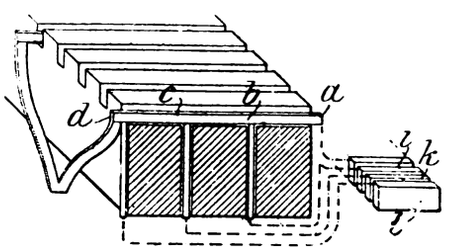
The Magnetic Survey of South Africa.—An account of their survey regarding the magnetic features of South Africa was presented to Section A of the British Association by Profs. Beattie and Morrison. The survey was started in the summer of 1897-1898. The observational work has been carried on since that time whenever opportunity offered; naturally it was greatly interfered with by the war. Soon after the declaration of peace the various South African Governments each contributed to a fund for paying the expenses of a field party for a year's continuous work. This party observed during the whole of 1903 and part of 1904. Financial assistance has also been received from the Government Grant Committee of the Royal Society. The necessary observations have been made at about 400 stations, distributed chiefly along the various

Digitized by Google

railways in Cape Colony, Rhodesia, the Transvaal, the Orange River Colony, and Natal, in the south of Cape Colony, the east of the Transvaal, the Basutoland border, and the north-west of Cape Colony. Observations have been repeated at 20 widely-separated stations for the purpose of determining the secular variations of the elements. The annual and the daily observations have been derived from the earlier work of Sabine in South Africa. It is hoped that the work of reduction will be sufficiently advanced by August to show isogonic and isoclinic maps of certain parts of South Africa.

Change of Pressure.—In our issue of July 28 we referred to the inquiry held on behalf of the Board of Trade into the proposed change of pressure in the municipal supply. It will be remembered that the Metropolitan Electric Supply Company had employed various pressures, while the Borough Council on taking over the undertaking desired to adopt a pressure of 240 volts. Certain consumers objected, contending that, in addition to the inconvenience and expense of the change, their insurance policies might be affected. The Board of Trade has decided to allow the change of pressure, subject to six conditions, the effect of which is that the undertakers shall pay the consumers an agreed amount for the alteration of apparatus, shall study the reasonable convenience of the consumers in effecting the alterations, and shall arrange matters with the insurance companies. It is also provided that the undertakers shall comply with the general terms imposed by the London County Council, who gave a conditional consent to the change. Any further differences between the parties shall be settled by an arbitrator to be appointed by the Board of Trade. The award impresses us as a very reasonable one, but, considering that the Borough Council were prepared in the first instance to do practically what is now directed, it is a little difficult to understand what need there was for an inquiry at all.

Reduction of Sparking.—A patent has been granted to Messrs. Siemens Bros. and Co. for a method of reducing the self-induction between adjacent commutator bars of a dynamo, thus reducing the sparking. Each turn upon the armature is tapped not only at the ends, shown in the



accompanying diagram (which we reproduce from the *Official Patents Journal*) as *a d*, but also at intermediate points, *b c*, by leads passing through the ventilating ducts or other passages in the armature core, and connected as shown to additional commutator bars, *i k*. This device may be serviceable in the case of large generating units driven at exceedingly high speeds, when the voltage per turn on the armature becomes high. The apparatus described practically divides the single turn into a number of sections, which are individually commutated. In this respect it is not unlike the method adopted in the large two-pole machines with which Messrs. Siemens Bros. held the market some years ago. In these machines parallel windings had to be adopted in order to give satisfactory commutation.

Northampton Institute.—The prospectus for the ensuing session shows that extensive preparations have again been made for providing instruction in electrical, mechanical, watchmaking, and horological engineering. The classes for the day courses commence on the 2nd prox., and for the evening courses on the 25th inst. The subjects are arranged in stages to suit all students from the tyro to the candidate for the B.Sc. degree of London University, for which there is a four-year day course and a five-year evening course. Instruction is provided for the various electrical examinations of the City and Guilds Institute, and the lectures are supplemented by work in the laboratories, which are admirably equipped. The advanced (C) section of the electrical engineering department should be of great value to those intending to enter the profession. The work is designed to bring the student into touch with the most recent developments in heavy electrical engineering. The complete course consists of lectures, design and laboratory work, and concurrent attendance at the corresponding mathematical classes is essential for all who have not previously studied the higher mathematics of electrical science. Experience has shown that the range of the subject renders it unwise to compress the work into a single session, and it has therefore been divided into sub-sections dealing with (1) the utilisation and (2) the design and manufacture of electrical machinery and apparatus. Altogether, the well-known Clerkenwell foundation bids fair to continue and increase its usefulness as a technical college.

Electricity in New Zealand.—An interesting hydro-electric plant of the three-phase type has recently been installed by a company at Inglewood, New Zealand, for a lighting and power supply, the engineers being Messrs. Steuart and Fenn, of Dunedin, who are the pioneers in the colony of this system, and who supplied the whole of the electrical machinery. The source of water power is the Ngatoro River, on which the intake and power-house are situated about 2½ miles from Inglewood. Observations of that stream for a considerable time during ordinary seasons and in droughts have demonstrated that there is very little danger of the volume of water diminishing to such an extent as to affect the power, and it is so steady as to render a dam unnecessary at the intake, an ample supply passing through the gates. The turbine, a twin machine of the "New American" type, develops 100 h.p. The alternator has a capacity of 45 kw., and energy is generated at 3,000 volts. As it is expected that there will be a considerable demand for power as well as lighting, the three-phase system was selected, this system being new to the colony with the exception of the installation at Hawera. The company have made provision for the installation of a second unit to meet the increased demand which they anticipate in the near future, by the construction of a second concrete main from the reservoirs to the power-house, and the provision of accommodation for duplicate plant. The poles supporting the power lines are of iron, and are remarkably straight and neat in appearance. The current for lighting purposes is transformed to 220 volts. The new illuminant has given great satisfaction to private consumers, and the demand is steadily increasing. It is expected that the dairy and manufacturing establishments in the town and neighbourhood will adopt electric power very shortly, and the additional machinery will then be installed.

New Publications.—The *Transactions* of the Faraday Society dated August contain papers on "An Application to Electrolytes of the Hydrate Theory of Solutions," by T. Martin Lawry; "Notes on the Rapid Electro-Deposition of Copper," by Sherard Cowper-Coles; "The Use of Balanced Electrodes," by Prof. W. W. Haldane Gee; "Electrolytic Oxidation of Hydrocarbons of the Benzene Series," by H. D. Law and F. M. Perkin; "Notes on Heat

Digitized by Google

Insulation, particularly with regard to Materials used in Furnace Construction," by R. S. Hutton and J. R. Beard; "Storage Batteries and their Electrolytes," by R. W. Vicarey; "Refractory Materials for Furnace Linings," by E. K. Scott; and "Alternating-Current Electrolysis," by Prof. E. Wilson.—The *Journal* of the Franklin Institute (Philadelphia) dated September contains the reports of the institute's science and art committee upon electrically-welded screw caps and bolts and Goldschmidt's system of alumino-thermics; and papers on "Mica and the Mica Industry," by G. W. Colles; "Sources of Supply and Methods of Manufacture of Phosphates and Potash Salts," by E. B. Voorhees; and "Superheated Steam in Locomotive Service," by W. F. M. Goss.—"Elementary Manual of Magnetism and Electricity," by Andrew Jamieson (London: Chas. Griffin and Co. 3s. 6d.). The sixth edition has been revised so as to bring the contents perfectly up to date, and a plate has been included from the painting by Acland Hunt of Dr. Gilbert showing his experiments to Queen Elizabeth.—"Molecular Forces and Newtonian Laws," by Alex. Clark, M.A. (Glasgow: W. and R. Holmes). In this volume the author discusses in a concise manner various physical, and especially electrical and magnetic, phenomena.—Amongst the contents of the July-August number of the *Proceedings* of the Society of Civil Engineers of France we note the speeches made at the funeral of the late president, M. F. Reymond, and a long article by M. G. Semenza on the hydro-electrical installations in Upper Italy. A map and sectional plans of the Vizzola works of the Lombardy Electrical Power Distribution Company, of Milan, accompany this article.

The World's Iron and Copper Supply.—In a recent issue of the *International Quarterly* Prof. N. S. Shaler discusses the importance to humanity of iron and copper, upon the former of which, as he remarks, our civilisation may be said to have been built. Its cheapness forms a considerable element of its value to man. Iron is a very widely distributed element, and the amount of iron ores still available is very great, perhaps twenty times as great as has been won to use. Some of the best-known fields, however, are beginning to be exhausted, and it is evident that, at the present rate of consumption of iron, the European sources of supply are not likely to endure for a century. In the case of copper, the sources of supply are very much rarer than those of iron, and the total amount of the metal in the crust of the earth is probably not more than the thousandth part of that of iron. The professor predicts that its supply will be reduced to a point where its service to the arts will be seriously limited before there is a like reduction in the supply of iron. He proceeds to state, however, that we can look upon the approaching exhaustion of the sources of copper with less apprehension than in the case of iron, for the reason that, useful as the metal is in manifold ways, it is not indispensable, or even very necessary, in our arts, except in the transmission of electric power, and even in that substitution is possible. Aluminium, he observes, is admirably adapted to serve most of the needs now served by iron and copper. It is relatively very light, but for its weight is admirably strong, rigid, tough, and elastic; it is a good conductor of electricity, and it does not oxidise as readily as do iron and copper. The amount of aluminium lying almost at the surface of the earth's crust is enormous, probably many thousands of times as great as the amount of iron contained in the concentrated form of beds or veins. Every clay bank is a possible source of the metal. Aluminium is never found in the metallic state, but in the form of silicates. Before it can be put to the uses of man, its union with the silicon must be broken up, and the work of separating the elements is very costly. With any methods now conceivable the professor opines that, while aluminium is likely in time to take the dominant place now held by iron, it will do so at a cost in terms of labour far higher than what men now pay for their capital metal. Nevertheless, the difference is not likely to be so great as to prevent aluminium from coming to the rescue of the mechanical foundations of our economic civilisation.

Mica.—The first chapter of an interesting article on "Mica and the Mica Industry" appears in the *Journal* of the Franklin Institute (Philadelphia) from Mr. G. W. Colles. The author commences with a description of the various classes of mica, which are somewhat numerous, and then deals with their physical characteristics. The most striking trait common to all the micas is the quality of being easily cleavable into thin, elastic, and generally transparent plates, and in this characteristic they find their economic usefulness. That mica has a strongly characterised polarity can be readily observed by striking a mica plate with a dull-pointed instrument on a yielding surface, which will cause the mica to become fractured. The lines of fracture extend in one or more of three principal directions, which make angles of 60deg. with each other, and form a six-rayed star. Another indication of strong hexagonal polarity is seen in the ruling and striation which often occurs in one or more of the three secondary directions. Most kinds of mica are practically infusible in ordinary heats. Subjected to the blow-pipe some of them, especially the lithia micas, are fusible with difficulty, yielding up a portion of their water. A very intense heat, such as that of the electric arc, will cause the mica to whiten and crumble locally, and even a low degree of heat, sufficiently prolonged, as in a stove or furnace wall, causes the mica to lose gradually its elasticity, and become brittle and friable. The softer pyroxenic micas are more easily decomposed by water than the granitic. Besides blending with one another, the micas pass in like manner by indeterminate gradations into other related and similar forms. As silicates they stand midway between the anhydrous silicates, on the one hand, of which the feldspars are examples, and the hydrated silicons on the other, of which the zeolites are most characteristic. It is interesting to note that many of the principal varieties of mica have been obtained artificially. By fusing various natural silicates (hornblende, actinolite, glaucophane, andalusite, garnet, etc.) with the fluorides of sodium and magnesium, micas corresponding to biotite, phlogopite, muscovite, and zennwaldite were obtained. Khruschoff describes the formation of margarite, biotite, and muscovite by fusing various bases with the constituents of lepidolite and an excess of silica, alumina, and alkaline fluorides. Vogt, of Sweden, also describes the occurrence of mica in slags. Notwithstanding this, however, the author states that there is not the least likelihood of artificial mica being produced on a commercial scale at a profit. These experiments merely explain some possible modes of origin of natural mica.

Electrical Machinery Insurance.—The insurance of electrical plant against accidents is becoming common, the great value of the insurance being the periodical inspection of the plant by an independent authority. The result is that the supervision by the owner's staff becomes more efficient, and the interruptions in the working of motors, dynamos, or other apparatus are reduced. We recently received a report of the British Engine, Boiler, and Electrical Insurance Company, whose head offices are at King-street, Manchester, in which there are given some interesting figures as to those parts of dynamos and motors which most frequently give trouble. From the breakdowns

Digitized by Google

which have occurred in machinery insured by this company the following tables have been compiled, showing the ratios in which the different parts of the damaged dynamos and motors are thought to have contributed to the total. The rate of breakdown among dynamos was 1 in 12, and among motors 1 in 9·3, excluding breakdowns of starting resistance switches, or 1 in 8·2 including them. The parts causing trouble, expressed in percentages, were as follow:

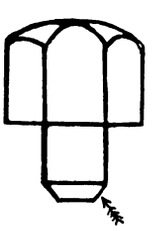
	Dynamos.	Motors.
Armatures and rotors	55	47
Magnets and stators	7	11
Commutators and brush gear	28	18
Miscellaneous	10	8
Switches and resistances	—	16
	100	100

The causes of the damage may be classified as under:

	Dynamos.	Motors.
Accidents	9	9
Dirt and neglect	13	19
Age and deterioration	38	25
Bad workmanship and design	20	16
Overloading	3	3
Causes not ascertained	17	28
	100	100

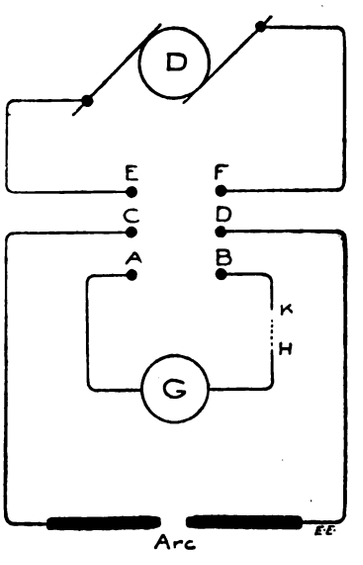
The report goes on to give a description of 23 so-called breakdowns, the majority of which could have been prevented with reasonable forethought and regular supervision and cleaning. An interesting case of an unexpected fault was the accident to the motor of a Blackman fan owing to the wind turning the fan in a wrong direction during a storm. This spoiled the copper brushes used on the commutator, and prevented the fan from working when it was next switched on. In a large number of instances the actual damage done before the inspector of the company was called in was exceedingly slight, and the breakdown was not such as to interfere for any length of time with the working of the apparatus involved.

Electrically-Welded Screws.—The *Journal* of the Franklin Institute (Philadelphia) for September contains a report by its science and art committee upon the wares of the Cleveland Cap Screw Company, the heads and bodies of which are welded together electrically. For the heads are used specially die-drawn stock, hexagon, square, or round, according to style of head required. This stock is drawn very accurately, with a variation not exceeding ·003. The heads are cut from the bar on automatic machines, which turn a projection or shoulder to the diameter of the



screw to be welded, as shown in the accompanying sketch. The heads and stems are placed in the moulding machine and held firmly by copper vices, which are clamped to gunmetal platens of large section, and to which are connected the terminals of the secondary circuit of the welder, which are moved on steel ways by hydraulic pressure. The sections to be welded are then brought together, thus completing the secondary circuit, the primary circuit being connected through a break switch operated by a foot lever. The current is allowed to pass through these sections until they are brought up to a welding heat, then released at the same time the pressure is applied, forcing the two together, expelling any possible slag or deteriorated metal and forcing up a burr. A transformer is built into the base of the machine, and is supplied with alternating current at 300 volts, which for 3in. bolts is about 97 amperes, and this is reduced to two volts and corresponding amperes—*i.e.*, about 14,500. As the two abutting surfaces are brought to the necessary heat the current is thrown on and off by a foot treadle operating the primary circuit, allowing the heat to become uniform over the section, and then when the proper heat is obtained the whole is forced together with a horizontal movement of the jaws holding the head, with a pressure of from 2½ to 6 tons, in some cases by hand power through the medium of gears or by direct hydraulic pressure. The placing of brass heads on steel-bodied bolts or any other combination of metals is quite as easily accomplished. The committee tested five of the screws on an Olsen machine by pulling the heads off, with the following results. The pieces tested were ¾in. screw bodies, with hexagonal heads, bodies 8in. long, without threads. The elongation was found to average ·23in. in 2in., varying from ·1in. to ·36in. The elastic limit per square inch was found to be 69,000lb, and the ultimate strength per square inch about 86,000lb. About 80 per cent. of the pieces gave way at the weld, with granular fractures. The conclusion reached, after testing the screws for torsion, was that at the welds or near them was the weakest point (not considering the bottom of threads of finished bolts), but that these points compare favourably with the tensile tests showing 80,000lb. per square inch, average angle about 90deg. In order to determine the structure of the welds, an all-steel bolt was cut longitudinally through the head and body to a point below the weld, then carefully polished and etched with acid solution. The surface showed a fibrous arrangement of the particles of the metal, and at the weld a line of about $\frac{1}{16}$in. wide of quite a different character with no fibre markings, but each side of this the lines of the fibre curved outward as would naturally occur in forcing them together when hot. The institute have decided to award the John Scott Legacy Premium and Medal to Mr. David J. Kurtz, the originator of the method.

Residual E.M.F. of a Carbon Arc.—Mr. G. G. Becknell describes in the September number of the *Physical Review* some experiments made to determine the E M F. between the carbon of an arc immediately after the arc is extinguished. In order to do this the circuit was so arranged that the dynamo and galvanometer could, by means of a double-pole three-throw switch, be alternately joined in series with the arc gap (see figure). It was found

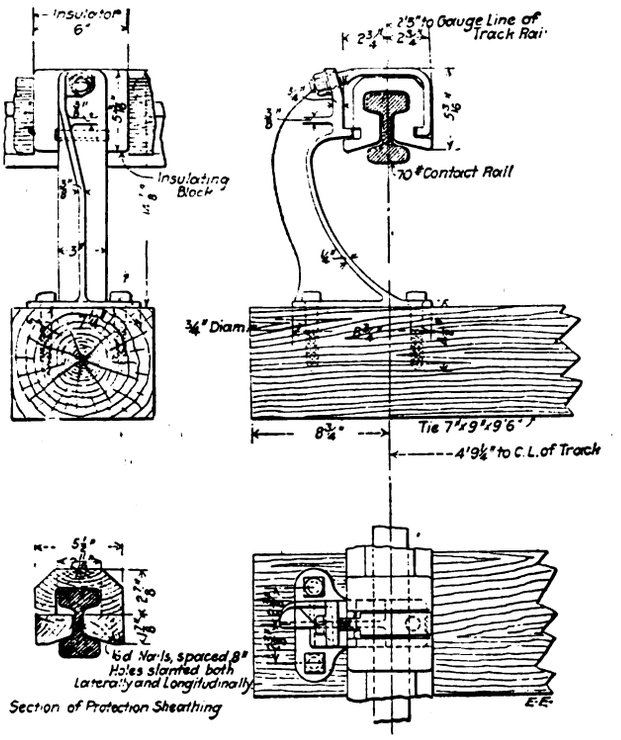


at once that a current, which we may call the residual current, could be observed for more than 10 seconds after the interruption of the arc; and it was seen, upon replacing

Digitized by Google

the galvanometer by a Weston voltmeter, that the residual E.M.F. was counter to that of the dynamo, and reached a maximum value of more than half a volt. In order to show something of the qualitative nature of the phenomena, the following simple experiments were tried: (1) A plate of either copper or mica—*i.e.*, a plate of material either conducting or non-conducting—when interposed between the electrodes without touching either of them, was sufficient to arrest the residual current entirely; but upon the removal of the plate the current was immediately re-established. This experiment with the copper plate shows that the residual effect can hardly be due to thermo-electric contact (whatever that may mean) between the heated carbon tips and the heated gases of the arc, for in such a case the interposition of a copper plate across the arc gap would tend to increase the current through the galvanometer, and certainly not to destroy it. (2) A short copper wire joining the positive and negative electrode was sufficient to stop entirely the residual current through the galvanometer, showing that the effect cannot be traced to a thermo-electric source existing outside the arc, for in this event the current would have been much increased by thus cutting out the resistance of the arc gap. We may fairly conclude then, perhaps, that the residual current is due neither to a thermo-electric effect in the arc nor to one external to it. (3) As a further test a gentle air blast was applied to the regions between the carbons at the instant when the galvanometer was thrown into the circuit. This, again, had the effect of removing nearly all traces of the residual current as long as the air current was continued, unless the poles were placed as nearly together as 1mm, and even then the effect was reduced to one-tenth. The failure at this point to completely destroy the effect was probably due to the partial inaccessibility of this small region to the current of air. It was found also that when the air blast was discontinued the residual current was set up again, provided the blast had not been applied for a time longer than four or five seconds. (4) It was observed also that if the galvanometer was thrown off and the dynamo thrown on to the arc gap for a few seconds, thus producing an electric field, but no arc, between the electrodes, a smaller residual current was re-established in the same direction as before—that is, counter to that of the dynamo. This effect could be detected if tried within a minute or two after the interruption of the arc. It would seem from these experiments—the interposition of the mica sheet and of the readily conducting copper, as well as the effects of the air blast and the renewal of the electric field—that we have here, not a case of ordinary electric conduction, but probably one of electric convection. This view is strengthened by the fact that the alternating arc gives a very small residual effect.

New York Central Third Rail.—In view of the numerous accidents which have occurred on electrified portions of English railways where a third rail is used to convey energy to the train, the following details of the construction adopted on the New York Central lines will be of interest. This construction is the outcome of extended trials on various methods of supporting the third rail on the Schenectady experimental track. The New York Central Traction Commission have finally adopted the under-contact type, as illustrated herewith. The system is the joint invention of Mr. W. J. Wilgus, fifth vice-president of the New York Central Railroad Company, and Mr. Frank J. Sprague, who is a member of the New York Central Electric Traction Commission. The working details of the system, including a complete system of crosses, switches, approaches, etc., have been developed under the direction of Mr. E. B. Katte, electrical engineer of the New York Central. The third rail is supported every 11ft. by iron brackets, which hold the insulation blocks by a special clamp. The blocks, which are in two pieces, are 6in. long by ¾in. in thickness, and are designed so as to be interchangeable. Experiments are now being conducted with insulators of reconstructed granite, vitrified clay, rubber, and indurated fibre to determine the relative advantages of these materials for the conditions under which they would be used. Between supporting brackets the upper part of the rail is covered by wooden sheathing. This sheathing, as shown, is applied in three parts, which are nailed together. At the joints where the third rails are bonded, and at the feeder taps, the wooden sheathing is mortised. The third rail is not mounted rigidly in the insulators, but is given a little play for expansion and contraction, except at certain central points, where it is anchored. It weighs 70lb. per yard, is of special section and composition, and has a resistivity between seven and eight times that of copper. The New York Central engineers have decided to place the rail 29in. from the gauge line. The under surface of the third rail is 2¾in



above the top of the service rail. The principal reason for adopting the under-contact rail is that it can be more thoroughly protected, and hence is safer than the ordinary type of contact rail. There are no projecting live edges or bolts, and no slot between the third rail and its cover through which an animal or any person ignorant of danger can make contact with the live conductor. The only possibility of reaching the third rail is from below and by an upward movement, and this fact, it is thought, greatly decreases the chance of injury from shock. Other advantages which it is claimed are possessed by this arrangement over the ordinary type of third rail are: (1) there is less strain on the insulators, as the pressure from the shoe acts against instead of with gravity; (2) the board protection, having a continuous support, is less apt to crack and warp; (3) the rail is more protected from the weather, and hence less liable to corrode; (4) the contact surface is more thoroughly protected from sleet and snow; (5) the construction is self-cleaning, and as there is a much greater space between the lower portion of the third rail and the tie, there will be less danger of an accumulation of snow, ice, and rubbish, and consequently less leakage. We are indebted for the above description to the *Electrical World*.

MESSRS. VICKERS, SONS, AND MAXIM'S ELECTRICAL MANUFACTURING DEPARTMENT.

When this firm took up the manufacture of electrical machinery some three years ago, they were specially equipped with information as to what class of motor and generator was best suited for driving heavy machine tools. Their own equipments at their large works at Sheffield, Barrow-in-Furness, Erith, and elsewhere had then been running for a considerable time, and in connection with the same a great deal of most valuable experience had been obtained. This was freely given to the profession at large in the historic paper by Mr. A. D. Williamson read before the Institution, entitled "Applications of Electricity in Engineering and Shipbuilding Works." Not only were the costs of production given for each of the nine plants run by the company, but also data as to the power needed to drive various machines. The results given prove to the hilt the many direct and indirect advantages of electric driving. Thus at Barrow a saving of half the coal bill was shown, concurrent with an increase of 50 per cent. in the output of the shipbuilding yards. The firm thus had exceptional experience of the behaviour of electric motors

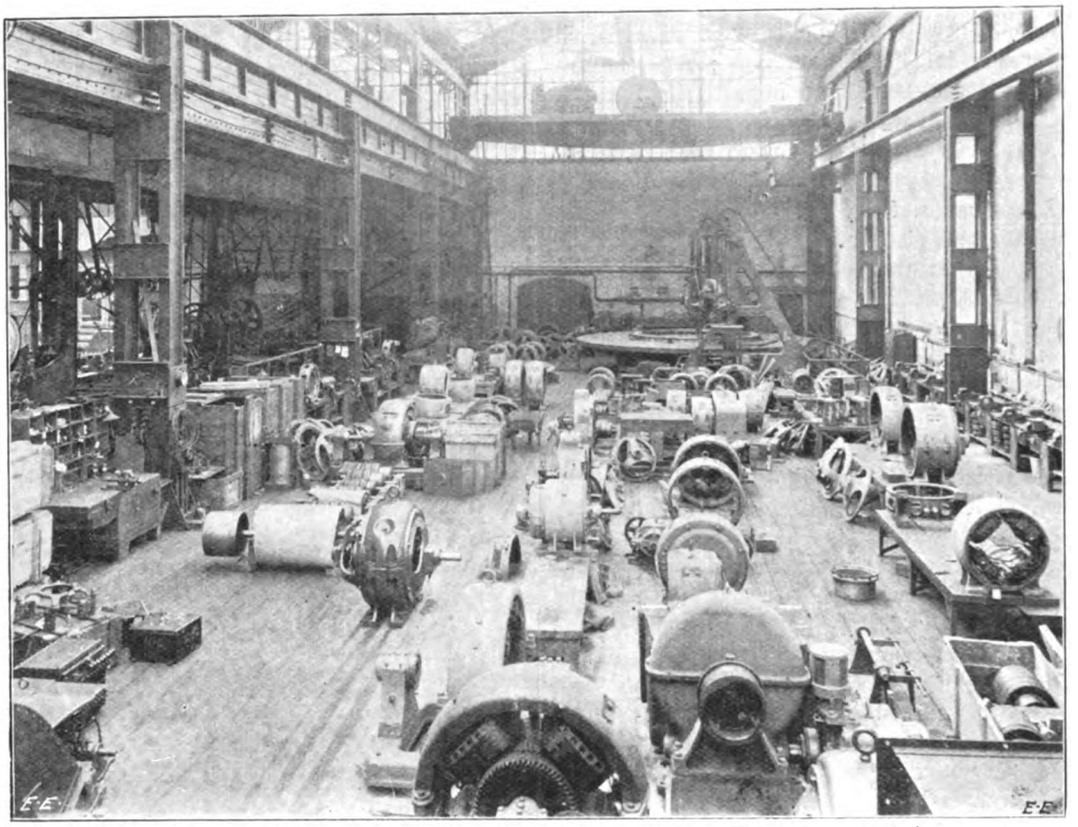

FIG. 1.—Part of the Electrical Machining and Erecting Shops of Messrs. Vickers, Sons, and Maxim.

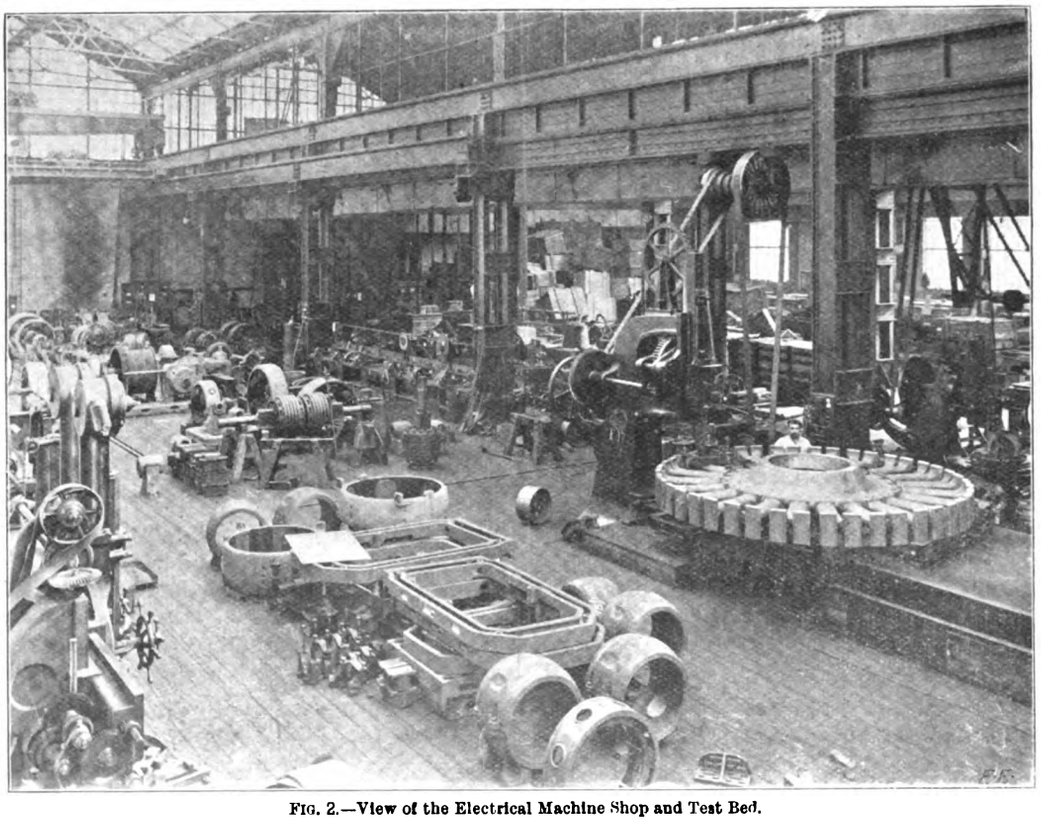

FIG. 2.—View of the Electrical Machine Shop and Test Bed.

Digitized by Google

of various types, and started their manufacturing department untrammelled by any obsolete patterns of their own. They were, therefore, in an excellent position to place upon the market machines embodying the latest ideas.

The electrical manufacturing department (Figs. 1 and 2) at the present moment occupies a shop consisting of four bays, 480ft. long by 40ft. wide, served by powerful electric cranes, and equipped with the most modern machine tools. In the Sheffield works no motors smaller than 5 b.h.p. are built, it having been decided to leave the small manufactures entirely in the hands of the Birmingham branch. The machine tools vary in size from a fine 24ft 6in. diameter boring mill down to the small lathes for tool-room use. Amongst other features worthy of notice are the tool-rooms, in which all tools and dies for electrical stampings are prepared. The stamping plant (Fig. 3) is capable of dealing with all sizes of discs and segments from the 5-b.h.p. to the 2,000-b.h.p. size. The resources of the firm are such that it has to buy very little outside finished material, insulated wire being practically the only material not finished in one or other of the departments of the firm. In the winding shop there is a well-equipped vacuum drying and impregnating plant for waterproofing all the coils as they come from the winding machines. The whole of the

mica used in the electrical manufactures is worked up on the premises.

Of course, the steel for the shafts is manufactured by the firm, and is of the highest possible class that the knowledge at their disposal can specify. The motors and generators when finished are tested either on testing pits (Fig. 4) or on the large erecting bed, there being a special generating set for testing alternating-current motors, consisting of a generator giving single, two, or three phase currents, driven by a 90-b.h.p. direct-current motor of variable speed, which allows the frequency to be changed from 40 to 60 periods. In the shops the following machines were in course of construction when we inspected the same recently: one 2,000-b.h.p. dynamo for gas-engine driving of their direct-current type for 460 volts, running at 100 r.p.m.; one 1,000-b.h.p. ditto; 30 motors of 100 b.h.p. each, variable speed, 150 300 r.p.m.; six coaling winches of 25 b.h.p. (as illustrated in Fig. 5); one five-ton winch; one three-ton winch; 20 motors of 30 b.h.p; six motors of 60 b.h.p, variable speed, 3 to 1 range; one 800-kw. 220-volt generator at 250 r.p.m.; several motors from 100 h.p. to 150 h.p.; some hundreds of motors of the constant-speed, variable-speed, and crane type, as well as alternating-current motors of all sizes from 5 b.h.p. to 100 b.h.p.

The above list shows the general character of the work turned out, which is practically all concerned with power

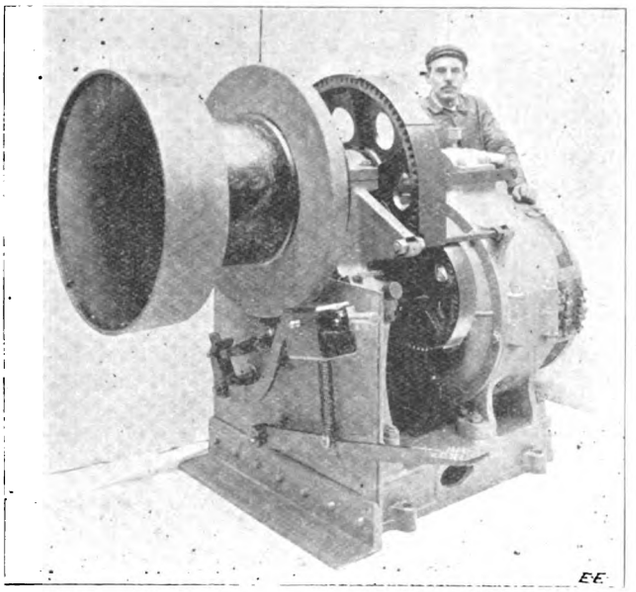

FIG. 5.—Vickers Electrically-Driven Coaling Bollard to lift One Ton at 200ft. per minute.

distribution. Messrs. Vickers, Sons, and Maxim have made a special study of variable-speed motors, and in their machine shops are several hundred motors to work with a 3 to 1 range of speed on shunt regulation. In several cases the motors have a speed range of 6 to 1; a good many are being made of 8 to 1 range for gun-training gears, and a motor of 15 to 1 range is being manufactured for a special purpose. A great deal of Admiralty electrical machinery is built at the Sheffield works, including electric light sets, winches, and hoists, training and elevating motors for guns, electric ventilating fans, etc. One special application of the variable-speed motor is that of driving planing machines by a method patented by the firm. A planing machine equipped in this way is to be shown at the Olympia exhibition next week. This type of planer is driven by a single motor with a range of speed from about 300 to 900, the motor driving the machine through spur or worm gearing. On the cutting stroke the motor runs at its slowest speed, and at the end of the stroke, the length of which is easily adjusted to suit the work, the motor reverses automatically. As soon as the reversal has occurred a resistance is automatically inserted in the field winding, quickly raising the speed to 900 for the return stroke. At the end of the quick return stroke, immediately before reversal, the field resistance is short-circuited, providing a strong field for reversing in, and the motor reverses and makes its slow cutting stroke, the cycle repeating itself. In order to start up or stop a planer driven by this gear, it is only necessary for the operator to throw over a simple switch.

The special switches for this control are illustrated in Fig. 6. The function of these switches are (*a*) to start the motor after it has come to rest at the end of the stroke; (*b*) to insert or withdraw resistance in series with the field coils, thus altering the speed after reversal; (*c*) to reverse the armature connections, and thus reverse the direction of rotation; (*d*) to retard the armature at the end of the stroke by strengthening its field prior to reversal. It should be particularly noted that the speed variation of the motor is produced entirely by varying the shunt current, and the efficiency of the motor is not less than 87 per cent. under any circumstances.

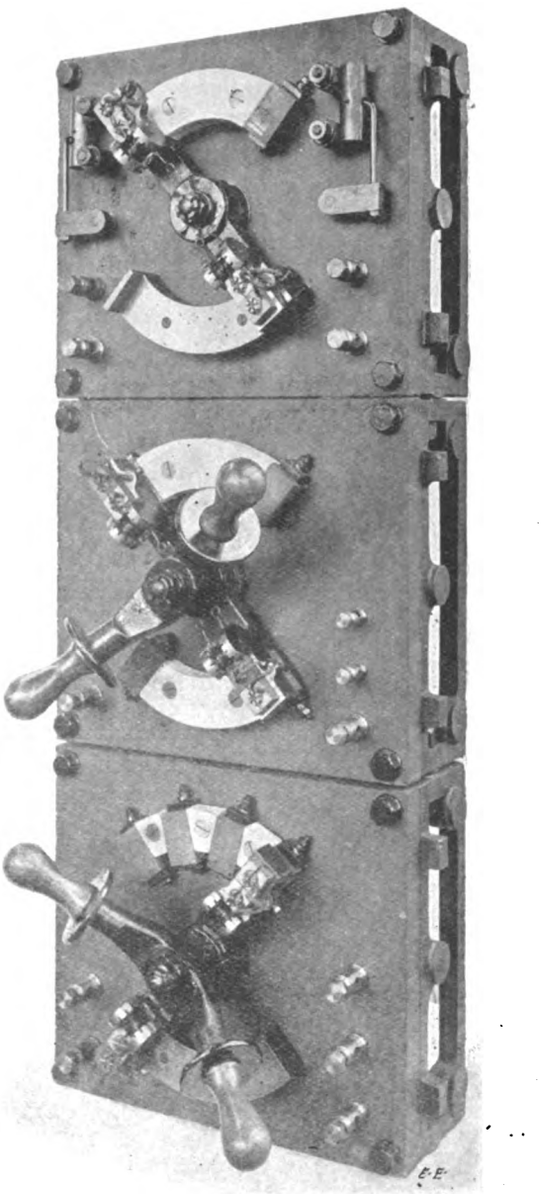

FIG. 6.—Switches for Controlling Electric Planing Machine by Vickers Patent System.

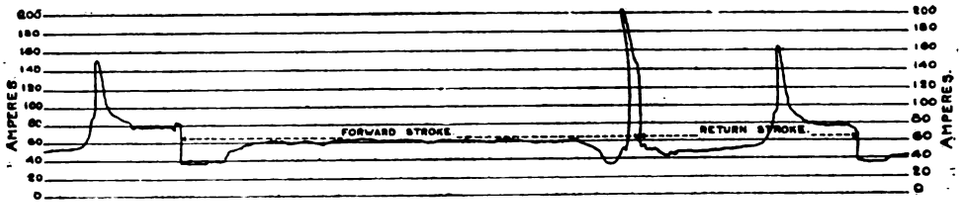
The advantages of this method of direct driving planing machines are many, and involve saving both of time and energy. The absence of belts is one great feature, which involves a great loss of saving in upkeep The cost of belts for a large planer averages from £30 to £40 per annum, and the rapid wear of the same is an indication of the energy wasted at the reversal of travel. As a rule the speed of cut is invariable with a belt-driven machine, which is not the case with the Vickers motor drive. This feature at once makes the planing machine of far greater value than it has been hitherto. The cutting speed can be instantly suited to the material from the hardest steel to softest steel and wrought iron, thus increasing the general output of the machine. The reversal is also more positive and quicker than that obtained by belt driving, and there is

Digitized by Google

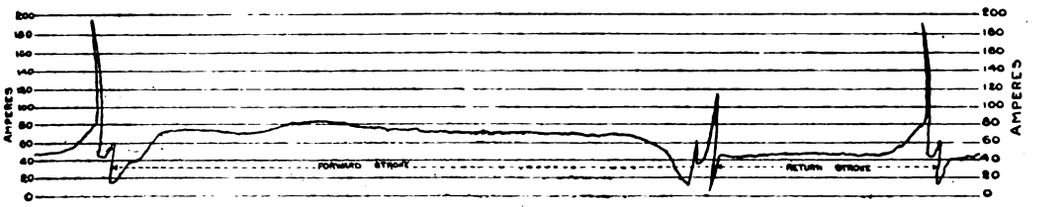
no loss of time at reversal such as is often seen with a belt which has become slack or worn. The shriek of the belts on reversal is caused by slipping, which wastes time and also energy. The question of the new method in the minds of electrical engineers will be as to the success of reversing the direction of rotation of a motor so often. This has been carefully gone into by the makers, who are so assured that their electrical department have in progress the alteration of 16 large planing machines in their Sheffield works alone. The decision to alter these machines was arrived at after very severe tests of the new system. One 12ft. by 10ft. by 24ft. armour plate planer, driven by a 20-h.p. variable reversing motor, was worked 24 hours a day for over six months. On short-stroke work it frequently had to reverse over 6,000 times each day, and at the end of six months the switches and motor had not deteriorated in the least.



POWER DIAGRAM.—ORDINARY BELT DRIVEN PLANER.

FIG. 7.

The two curves (Figs. 7 and 8) are power diagrams from two motors driving planers. Fig. 7 is from a test made on a Niles planer No. 106, size 10ft. by 12ft. by 25ft., which was belt driven in the usual manner by a 40-h.p. constant-speed motor. The travel of tool was 16ft. 6in., the average rate of cutting 13ft. 4in. per minute, and the average rate of return stroke 27ft. 6in. per minute. Fig. 8 is prepared from a test made on a Sharp-Stewart heavy planer No. 108, size 12ft. by 10ft. by 24ft., driven by a Vickers 20-h.p. variable-speed motor in conjunction with Vickers patent automatic reversing gear. The motor speed on cutting stroke was 370 r.p.m., and the speed on the return stroke 1,000 r.p.m. The travel of the tool was 20ft. 6in., the average rate of cutting 15ft. 5in. per minute, and the average rate of return stroke 41ft. per minute. These diagrams show the advantages of the direct drive most clearly.



POWER DIAGRAM.—PLANER DRIVEN BY VICKERS' SYSTEM.

FIG. 8.

Other special applications of variable-speed motors are being devised by the firm. We have, however, said enough to indicate the magnitude and variety of Messrs. Vickers's electrical output, and it is pleasant to note that the department is making such rapid strides.

THE EDDY-CURRENT BRAKE FOR TESTING MOTORS.*

BY D. K. MORRIS, PH.D., AND G. A. LISTER, ASSOCIATE MEMBERS.

(*Concluded from page 384.*)

WORKING OF THE BRAKE.

One of the characteristics of the brake is the steady manner in which the lever floats after the magnetising current has been adjusted. This is due to the fact that the centre of gravity of the sliding weights is slightly below the centre line. This feature is obtained without any material reduction in the sensitiveness. Another noticeable feature when using the brake is the absence of trouble due to end play of motor. This is extremely serious in the case of brakes in which the copper disc is mounted on the motor spindle while the magnet system rests on a separate frame. It is found that by the use of properly suspended flexible leads the magnet coils can be supplied with current without the use of mercury cups. The limit to the absorption capacity of the brake is determined by the heating of the magnetising coils. The fan action referred to is found to be an entirely satisfactory way of getting rid of the heat generated in the discs. Long-continued tests give rise to no difficulty at all on this account. The brake was originally designed to absorb 5 h.p. when running at 1,000 r.p.m., and it has been found to work most efficiently at speeds of this order. At speeds above, say, 1,500 r.p.m. the falling off of braking effect due to field distortion becomes noticeable, and at speeds lower than 500 the magnetising current required to brake, say, 5 h.p. becomes too great for the capacity of the coils. Fig. 4, Curve II., shows the absorption capacity of the brake for given

* Paper read before the Birmingham Local Section of the Institution of Electrical Engineers.

Digitized by Google

excitations at 1,000 r.p.m., and Curve II.A under same conditions for 1,750 r.p.m.

The brake is found very convenient for testing motors as regards temperature rise and overload capacity. When temperatures have settled down, and the magnetising current is finally adjusted, the load remains perfectly constant. Motors may be tested for starting torque by locking the revolving discs to the fixed portion of the brake

Figure of Merit.—In any type of eddy-current brake it is important that the power absorbed in the magnetising coils be kept down as low as possible. The ratio $\frac{\text{absorption power of brake}}{\text{power absorbed in magnetising coils}}$ may conveniently be termed the "figure of merit" of the brake. This figure should be as high as possible over the whole range of the brake, but more especially at or near its full rated capacity.

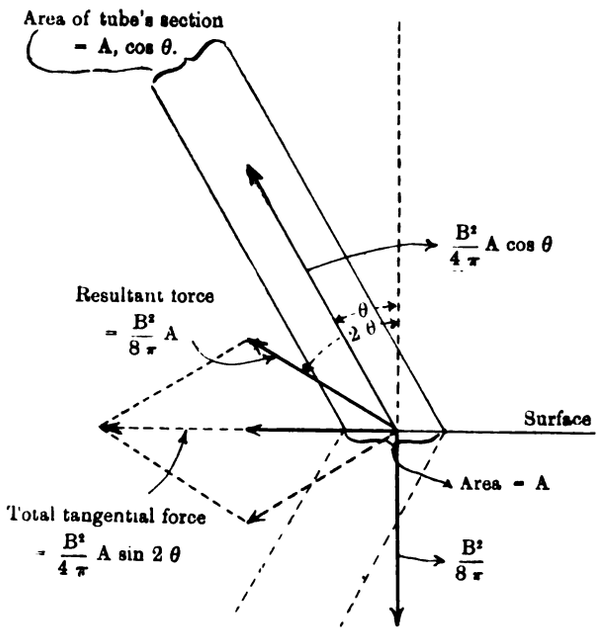

FIG. 7.

It is at this point it will be most frequently used, especially in connection with time tests. The figure of merit will, of course, rise with the speed.

THEORY OF THE EDDY-CURRENT BRAKE.

(*a*) *Introduction.*—The theory of the eddy-current brake is in many respects the same as that of the induction motor, with the additional simplification that inductance is absent from the rotor. The presence of poles, however, renders the ordinary induction-motor theory unsatisfactory. The theory here given is in many ways a very direct one. It takes account of the increase of reluctance of the air-gap due to the oblique path of the flux through the gap. This is not commonly done in dealing with the induction motor.

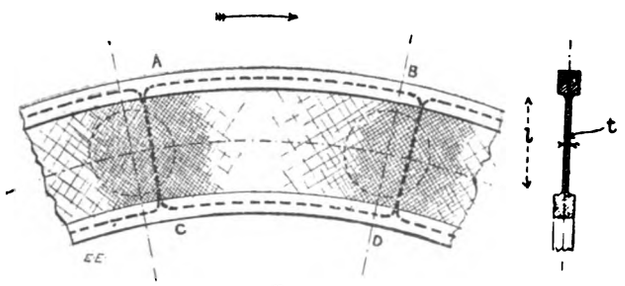

FIG. 8.

It is not necessary when the slip is small, but becomes an important factor when dealing with starting torque. Maxwell showed* that in air there is a tension along tubes of flux equal to $B^2/8\pi$ dynes per unit of area of the tube's cross-section, combined with a pressure in all the directions which are at right angles to the tubes of flux, also equal to $B^2/8\pi$ dynes per unit of area. This condition is equivalent, as he also states, to a hydrostatic pressure of $B^2/8\pi$ dynes per square centimetre combined with a longitudinal tension of $B^2/4\pi$ dynes per unit area of the tube's cross-section. Thus, if a tube of magnetic flux reaches a surface of area A at any angle θ to the normal, so that its section is A . cos θ, then the two forces acting on that surface are as shown in Fig. 7—namely, a tension along the direction of flux of $\frac{B^2}{4\pi}$. A . cos θ, and a simple pressure upon the surface of $\frac{B^2}{8\pi}$ A. The resultant force on the area A is, therefore, $B^2 A/8\pi$, and its direction is at an angle 2θ to the normal, so that the tangential force is $\frac{B^2}{8\pi}$ A . sin 2θ.

In the case of a brake disc, where the flux is bent so that it leaves at a similar angle on the opposite surface, the force is $\frac{B^2}{4\pi}$ A . sin 2θ, and since B cos θ is the flux density B_o as the flux crosses the surface normally, the force exerted by the magnetic field on the brake disc area, A, is $\frac{B_o^2}{2\pi}$. A . tan θ.* The flux produced in the air-gap by each magnetised pole can, if the latter are suitably shaped, be regarded as approximately sine-functional both when the brake disc is at rest and when it is in motion. In the latter case, however, it is dragged forward in the direction of rotation on account of the magnetic action of the currents induced by the motion. The width of this equivalent sine-functional flux-band may be less than the pole-pitch if the poles are not sufficiently wide, as in the brake described.

These induced currents give rise to a magnetomotive force tending to set up a flux lagging behind them in position by exactly half the pole-pitch. This magnetomotive force, however, operates upon a magnetic circuit of irregular and much greater reluctance than that of the original flux path, and the greater it can be made the less is the reaction caused by a given flow of eddy currents. The eddy currents are at any point coincident in position with, and proportional in magnitude to, the actual or resultant flux which crosses the disc at that point. The eddy-current paths remain fixed in space, so that the flux associated with them has not to be altered, and the energy corresponding to this flux is provided once for all. Only changes in this energy could give rise to inductive effects. The current flow will, however, be slightly hindered as it enters the thick rims on account of skin effect.

The following notation is employed†:

B_m = maximum value of original or main flux	2,200 lines per cm.²
B_r = maximum value of resultant flux measured perpendicular to disc in the disc itself	1,370 „ „
p = width of equivalent sine-functional flux in cms. measured along pole-centre line	3·8cm.
β = ratio of this width to the pole-pitch ($p \div \beta$ = pole-pitch)	0·31.
b = shift of resultant flux wave from position of main flux	0·55cm.
a = radius of swing of flux lines in cms.	0·7cm.
t = thickness of disc in cms.	0·4cm.
2 g = gap between pole-face in cms. ...	0·9cm.
ρ = specific resistance of material of disc in C.G.S. units per cm. cube (hot)	2,450.
l = radial length of average eddy-current path (see Fig. 7)	2·25cm.
α = resistance factor	2.

* "Treatise on Electricity and Magnetism, vol. ii., pp. 280 and 281 (third edition).

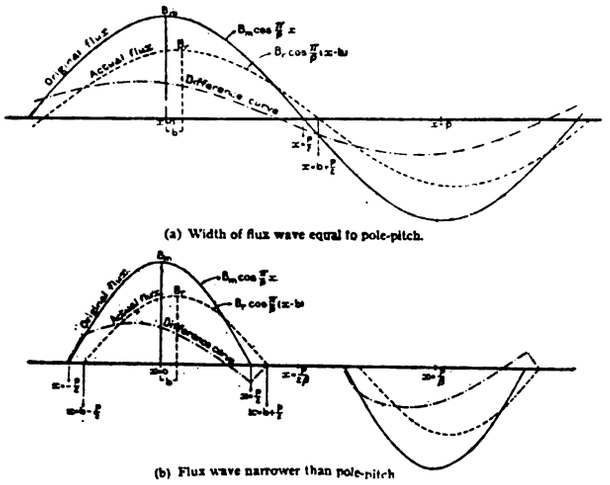
* The normal force can be similarly derived. Its value for an iron-cored armature—namely, $\frac{B_o^2}{8\pi} A . \frac{\cos 2\theta}{\cos^2 \theta}$, where θ is evaluated as explained below—is an important expression which should be used when dealing with bending stresses on the shafts of running armatures if placed unsymmetrically with respect to the poles.

† The values given on the right are approximately correct for the brake described in the paper when running at 1,000 r.p.m., and excited so that it absorbs 5·1 b.h.p.

Digitized by Google

v = speed of disc at effective pole-centre line in cms. per sec. ... 1,520cm. per sec.
R = speed of motor in r.p.m. ..... 1,000 r.p.m.
D = diameter of disc at pole-centres in cms. ..... 29cm.
x = distance measured along disc at pole-centre line in cms.

It will be readily seen that if the bands of flux be developed along the line of pole-centres on the disc, as in



(a) Width of flux wave equal to pole-pitch.

(b) Flux wave narrower than pole-pitch

FIG. 9.—Approximate Flux Distribution—Standing and Running.

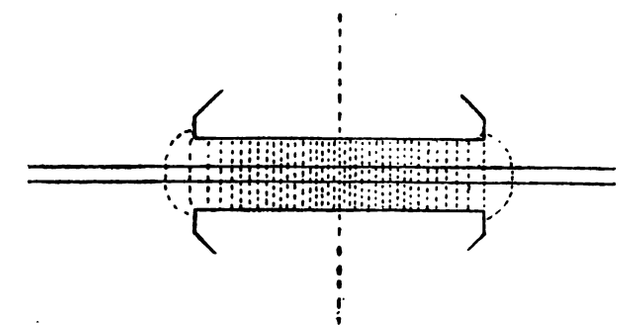
Figs. 9A and 9B, then the original or main flux can be denoted by

$$B_m \cos \frac{\pi}{p} x, \text{ between } x = -\frac{p}{2} \text{ and } x = +\frac{p}{2},$$

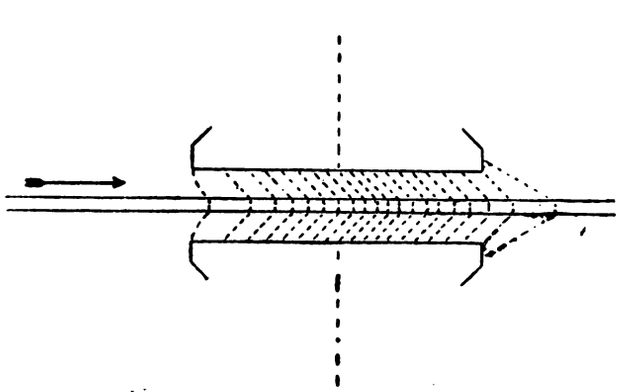
and the resultant flux by

$$B_r \cos \frac{\pi}{p}(x-b), \text{ between } x = b - \frac{p}{2} \text{ and } x = b + \frac{p}{2}.$$

(These limits need not be specified where the flux-band occupies the whole pole-pitch—*i e*, where $\beta = 1$.)



(a) Flux in gap when disc is at rest



(b) Flux in gap when disc is in motion.

FIG. 10.

(b) Flux Displacement.—The flux across the gap when the disc is at rest is depicted in Fig. 10A; and when the disc is in motion, the flux is dragged forward in the direction of rotation as indicated in Fig 10B, and is weakened in intensity owing to the increased length of the path in air. Thus a particular tube of flux meets with successive displacements with increasing disc speeds in the manner shown in Fig. 11. The shift of the tube along the pole-face is restricted in amount by the proximity of the forward edge of the pole. Thus, though the tube moves inside the pole-face nearly parallel to itself, the displacement of its path in the gap may be represented by rotations round fixed points, *o o'*, inside the pole-face, whose position is dependent upon the formation of the pole. The distance of these points within the pole-face is very small (1mm. or 2mm.), since it merely represents the excess reluctance of the whole magnetic path over that of the air-gap alone. In other words, the equivalent air-gap is greater than the actual. Assume that one such point, O, is a centimetres from the central plane of the disc, and that this centre of rotation is situate at a similar distance for every tube of flux. The displacement of the tube as it crosses the disc is b centimetres. Assume, further, that the reluctance of the whole magnetic path is dependent solely upon the length of its passage through the equivalent air-gap and the effective narrowing of the pole-surface due to forced obliquity of the flux. The density of the oblique flux is $B_m \cdot \cos \frac{\pi}{p}(x-b) \cdot \cos \theta$, which is further reduced to $B_m \cdot \cos \frac{\pi}{p}(x-b) \cdot \cos^2 \theta$ as it crosses the disc. Consider an element of the surface of the disc of radial

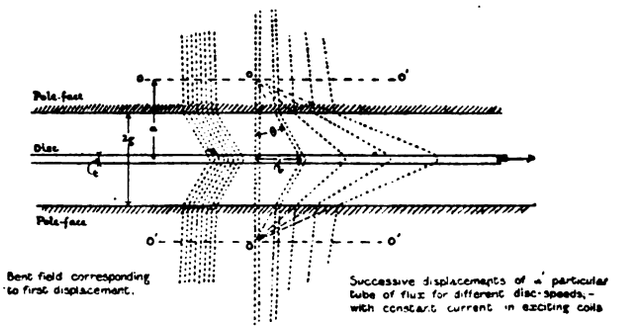


FIG. 11.

length l and with dx. The retarding force on this element is (see above)—

$$\frac{1}{2\pi} \cdot B_m^2 \cos^2 \frac{\pi}{p}(x-6) \cdot \cos^4 \theta \cdot l\, dx \cdot \tan \theta,$$

where $$\theta = \tan^{-1} \frac{b}{a}.$$

The force per pole is obtained by integrating this expression between the limits $x = b - \frac{p}{2}$ and $x = b + \frac{p}{2}$; and, if the flux falls on the disc with a uniform slope, as indicated in Fig. 10B, then the retarding force is $\frac{B_m^2}{4\pi} \cdot p\, l \cdot \sin \theta \cos^3 \theta$ dynes per pole. To obtain the total retarding force on the whole disc, this expression must be multiplied by the number of poles, n, and, since $n \cdot \frac{p}{\beta}$ is the circumference, πD, of the pole-centre line of the disc, the total retarding force on the disc is

$$\frac{1}{4} \cdot B_m^2 D\, l \beta \cdot \sin \theta \cdot \cos^3 \theta \text{ dynes}$$

exerted at radius $\frac{D}{2}$. The disc thus absorbs

$$\frac{1}{10^7} \cdot \frac{\pi}{4} \cdot B_m^2 D^2 \cdot \frac{R}{60} \cdot l \beta \cdot \sin \theta \cdot \cos^3 \theta \text{ watts,}$$

or, $$1{\cdot}76 \times 10^{-12} \cdot B_m^2 D^2 R \cdot l \beta \cdot \sin \theta \cdot \cos^3 \theta \text{ B.H.P.}$$

This can also be written as

$$0{\cdot}44 \times 10^{-12} \frac{N_t^2 R}{l \cdot B} \sin \theta \cos^3 \theta \text{ B.H.P.}$$

where N_t = total passage of flux across the disc when at rest $\left(= \frac{2}{\pi} B_m\, p\, l\, n\right)$.

(c) Slope of Flux for Maximum Torque a a Given Speed. The expression $\sin \theta \cos^3 \theta$ varies in the manner indicated

Digitized by Google

in Fig. 12. It is easily shown that its maximum value, 0·325, occurs for $\theta = 30$deg. The curve is plotted to a base of tan θ, since $b = a \tan \theta$. Thus the best inclination of this flux in the gap is when $\frac{b}{a} = \frac{1}{\sqrt{3}} = 0{\cdot}577$, and this occurs only when the disc has a thickness to be determined below. The greatest amount of power that can be taken up in a given brake disc is, therefore,

$$5{\cdot}7 \times 10^{-13}\ B_m^2\ D^2\ R\ l\ \beta\ .\ \text{B.H.P.}$$

(*d*) *Best Thickness of Eddy Current Disc.*—The bands of flux which cross the disc were found to have a density (B) at the point of crossing of

$$B = B_m\ .\ \cos^2\theta\ .\ \cos\frac{\pi}{p}(x-b).$$

Consider a radial element of the disc (see Fig. 8) of length l and average section $t\ .\ dx$. The E.M.F. induced in it is $B\ .\ l\ .\ v$. But the resistance of the circuit in which this E.M F. has to operate is greater than $\frac{l\rho}{t\ .\ dx}$ by one-half the resistance of the portions A B and C D. Let the increased resistance be $\frac{a\ .\ l\rho}{t\ .\ dx}$, where a should have a value of 1·2 to 1·5. The actual path of the currents will be approximately radial only when the rims are thickened, as shown in Fig. 8. Since inductive back E.M.F. does not

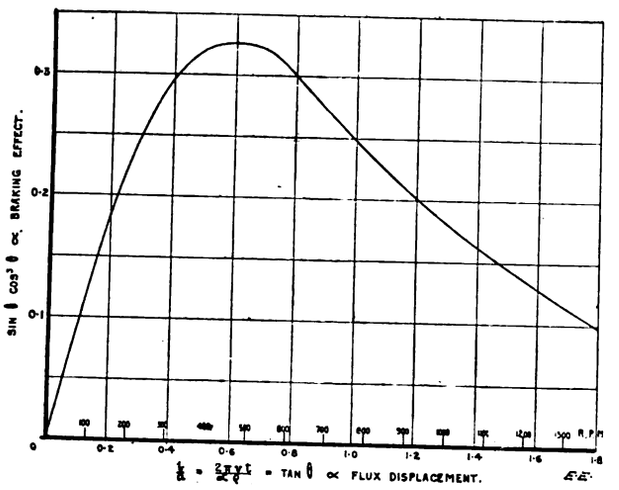

FIG. 12.—Variation of Torque with Flux Displacement.

arise in the eddy-current path, the current induced in the element is

$$dc = \frac{v\ t}{a\ \rho}\ B\ .\ dx,$$

and the current per centimetre width of disc is dc/dx. This will cause at the surface of the disc a flux of $2\pi\ .\ dc/dx$ lines per square centimetre parallel to the surface, and a similar flux oppositely directed on the other surface of the disc. The bend in the magnetic lines as they pass through the disc is effected solely by these two fields. In order that a flux of value B may be bent through an angle θ by a flux of $2{\cdot}\pi\ dc/dx$ at right angles to it, it is necessary that the former be related to the latter in the ratio 1 : tan θ (see Fig. 13), or as a to b. Hence, inserting the value of dc/dx, the flux displacement is given by

$$b = a\ .\ \frac{2\ \pi\ v\ t}{a\ \rho},$$

also $$t = \frac{a\ \rho}{2\ \pi\ v}\ .\ \frac{b}{a}\ \text{cms.} = \text{thickness of disc.}$$

Inserting the most advantageous value of b/a already determined, it is seen that the eddy-current brake disc should have a thickness between the pole-pieces of

$$t = \frac{a\ \rho}{2\ \pi\ \sqrt{3}\ v} = 0{\cdot}092\ a\ \frac{\rho}{v}\ \text{cms.}$$

Any greater thickness will result in *decrease* of torque.

(*e*) *General Expression for Brake Horse-Power Absorbed by Eddy Disc*—The power absorbed by an eddy brake disc with radial current flow is

$$1{\cdot}76 \times 10^{-12}\ B_m^2\ D^2\ R\ l\ \beta\ \sin\theta\ \cos^3\theta\ \text{B.H.P.},$$

where $$\theta = \tan^{-1}\frac{2\ \pi\ v\ t}{a\ \rho}.$$

The values of sin θ cos^3 θ are given in the curve (Fig. 12).

APPLICATION OF THEORY TO DESIGN OF EDDY BRAKES.

This theory leads to the following points of design:

1. The rims of the brake disc should be thick compared with the thickness between opposing pole-faces, so that the currents may flow approximately radially (Fig. 8).

2 When this condition is attained, the brake disc's thickness in millimetres should be about equal to the specific resistance of its material in C.G.S. units when heated — say, about 2,500 for copper and 4,000 for aluminium—divided by the average linear velocity of the disc. For the brake described in the paper, when running at 1,000 r.p.m. or a mean linear velocity of 1,600cm. per second, the best disc thickness is about 1·7mm. if the disc rims were thickened, and probably about 3mm. with a plain disc.

3. The pole-faces must be so designed that the point round which the lines of flux swing is but little within the pole-face. It is proposed to meet this condition by a series of radial cuts or narrow slots in the pole-face. The observations on the brake described in the paper show that this point of swing is at present on the average about 2·5 within the pole-surface (see Fig. 11), while the flux displacement with the 4mm. disc is about 0·6cm. Under these conditions it will be seen that the eddy currents' magnetomotive force is beginning to operate upon a better magnetic circuit,

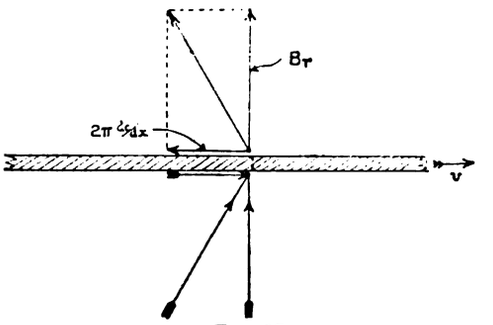

FIG. 13.

and not only to cause a reduction in the main flux, but also to give rise to a flux along the pole-surfaces tending to increase the flux displacement.

4. The radial lengths of the pole-faces should be as great as is convenient, the gap being made a shade less on the outside, so that the flux may not suffer radial displacement. And, generally, the polar area should be increased (making β nearly equal to unity), and the gap reduced as far as practicable in order to economise in magnetising energy. A limit to this increase arises, however, if the magnet cores are approaching saturation, on account of the diversion of the flux through the leakage paths between the sides of the poles without crossing the disc at all (Fig. 3). Approximate investigation seems to show that the best value of β is about 0·7, when the pole-faces have a width about equal to one-half the pole-pitch. If an allowance of 25 per cent. be made for the reduction in flux arising through leakage combined with core saturation, the following expression

$$3 \times 10^{-13}\ B_m^2\ D^2\ R\ l\ \text{B.H.P.},$$

would appear to represent roughly the *maximum* brake horse-power that can be absorbed in a given brake disc running at the speed which is most advantageous for the thickness of brake disc employed. Putting $l = {\cdot}15$ D, which represents as long a pole-face as is convenient, the expression becomes

$$4{\cdot}5 \times 10^{-14}\ B_m^2\ D^3\ R,$$

or, at 1,000 r.p.m., $$4{\cdot}5 \times 10^{-11}\ B_m^2\ D^3.$$

For a disc 15in. in diameter over all this becomes approximately

$$1{\cdot}35\left(\frac{B_m}{1{,}000}\right)^2,$$

or 6·5 b.h.p. per disc, with the flux densities occurring in the brake described in the paper. This brake, with its

Digitized by Google

two discs, should, therefore, be capable of absorbing 13 b.h.p. at 1,000 r.p.m. if the best design could be followed.

CONCLUSION.

The authors have compared the theory here given with the results actually obtained on the brake described in the paper, and have found throughout as substantial an agreement as can be looked for, considering that the theory applies properly only to a copper disc with thickened rim. When it is remembered that this brake was designed before the theory as to correct proportions was worked out, and that by (*a*) reducing thickness of disc, (*b*) providing it with rims as in Fig. 8, (*c*) widening the pole-faces, and (*d*) slotting them, an increase of capacity amounting to over 100 per cent. should result, it will be seen that it may fairly be claimed for the eddy-current brake that besides being quite the most convenient and compact for ordinary motor testing, it will compare favourably, when correctly designed, with mechanical water-cooled brakes in all respects except that of initial cost. A brake embodying these improvements is being designed, and it is hoped that an early opportunity will be found of constructing it.

In conclusion, the authors wish to express their thanks to the council of the University of Birmingham, through whose action they have been enabled to carry out this work.

THE DISTRIBUTION OF POWER.*

BY PROF. AYRTON, F.R.S.

Twenty-six years ago, at the meeting of the British Association at Sheffield, August, 1879, a lecture on "Electricity as a Motive Power" was delivered to some thousands of working-men, and, for the first time, they realised that forks and spoons could not merely be plated with the electric current, but could also be polished with a brush made to spin with the same agency. The sea of upturned faces beamed with delight when Jack, their popular comrade, stepped on to the platform, took the newly-plated spoon in his hands, and burnished it—a pair of thin wires tied to a church steeple being the only connecting link between the dynamo machine in a neighbouring works—ordinarily used there for electroplating—and the electromotor driving the polishing brush in the Albert Hall, Sheffield. But an electromotor is only a toy, thought my audience; nobody could construct an electromotor that we could not stop with our hands. And at the end of my lecture they actually tried, and—wondered.

As far as I am aware, it was at that lecture that this composite suggestion was first put forward—viz, to obtain economy in electric transmission of power the current must be kept small, while to transmit much power the electric pressure between the conducting wires must be made large; and, lastly, to secure safety and convenience in working, this high pressure must be transformed down into a low one at the distant end of the transmission system. But what did high pressure—produced with a dynamo—mean 26 years ago? Why, three or four hundred volts—what, in fact, is called low pressure to-day—a pressure less than is now often used for lifts in buildings, pumps in mines, and tramcars in streets. And how was it proposed to transform this so-called high pressure into a low one? Why, I suggested mechanically coupling a 400-volt direct-current motor to a 50-volt direct-current dynamo—the device that has since been called a "motor-generator"—and such a combination was shown in operation at that lecture.

But it was in Paris, at the Palais de l'Industrie, the home of that electrical exhibition of 1881—which has now become classical—that modern electrical engineering was born, and shortly afterwards *Punch* exhibited the young infant thriving and imbibing liquid nourishment from a storage cell. "What *will* he grow to?" says the picture. What *has* he grown to? Aladdin's ring, Aladdin's lamp—whose slaves brought a fortune to him, and a fainting fit to his mother—were but poor magic makers compared with the ring evolved by Gramme and that boy Paccinotti—compared with the lamp constructed by those veterans, Edison and Swan. In the "Arabian Nights" it is stated that Aladdin's would-be uncle, the noted and learned African magician, knew that that within the wonderful lamp was not oil, and that he anticipated by many centuries the Johannesburg Municipality, who, to reconcile the inhabitants to having the electric pressure in their houses raised from 110 to 230 volts, offer—like that other African magician—to give "new lamps for old." It is also described how the lamp enabled Aladdin to carry off the Princess Badroulboudour, and the wicked uncle to transport the palace. But electric traction has carried off whole neighbourhoods out of cities into suburbs, and, by transporting hundreds of thousands daily, has helped to solve the problem of housing the working class. While electric distribution of power has discovered, not caves of buried jewels, but waterfalls of ever-flowing wealth. At the mines near Silver City, Idaho, for example, coal had reached 70s. a ton, wood 36s. a cord, for years the distribution of power was by donkeys, or long teams of horses slowly hauled the heavy loads of wood up the mountain road. Then the magician of this, the electric age, came to Idaho, and now the need of those mines, power—clean, dustless, weightless power—courses up the mountain side from Swan Falls on Snake River in the valley below. What fairy of old, from whose mouth fell jewels whene'er she opened it, ever worked such beneficent wonder? See how proudly those posts look down upon their conquest of the past. For have they not brought an end, not merely to wasteful extravagence in lifting fuel up to those mines, but also to needless toil for tired cattle? In 1886, when the boy Electricity was five, the babe Johannesburg was born, and the two youngsters have raced along neck and neck. Something of their lives I will tell you to-night.

Nine years after that first lecture the British Association honoured me by asking for another. In 1888, however, it was beginning to be realised that a pressure of 2,000 volts between electric mains might not make too great a call on the funds of life insurance companies. Alternate-current transformers had come into use; Ferranti was employing them for practically distributing electric current from the Grosvenor Gallery, Bond-street. A "transformation scene" Lord Kelvin called the apparatus at that lecture. The male white population of Johannesburg was now—2,000. But although current at 100 volts pressure was beginning to be distributed for electric lighting, the distribution of power for working electromotors was still but the dream of the future. In exactly a decade after the Paris Electrical Exhibition of 1881 came the Frankfort Exhibition of 1891. More than 10 times 2,000 volts was there used to transmit more than 100 h.p, more than 100 miles, with more than 75 per cent. efficiency. A death's head and cross bones were painted on every post along that 109 miles of railway line, Lauffen to Frankfort, for he who should touch these bare wires, with a pressure of 25,000 between them, secured electrocution. And a similar suggestion of mortality greets the wayfarer—in his own language, be he English or Dutch—on the posts of the Rand Central Electric Works. Table I. shows that the use of higher and higher pressures has enabled larger and larger amounts of power to be transmitted longer and longer distances, with greater and greater efficiency—that is, with less and less waste. Now, why is this?

TABLE I.

—	1882. Hirschau to Munich.	1883. Vizille to Grenoble.	1886. Creil to Paris.	1891. Lauffen to Frankfort.
Pressure at transmitting end in volts ...	700	3,000	6,000	25,000
Horse-power delivered by electromotor	5·8	7	52	114·2 to lamps
Distance in miles	3·5	8·75	35	108·7
Percentage commercial efficiency of transmission	36	62	45	75·3
Diameter of line wire in inches	0·18	0·079	0·2	3 wires each of 0·158
Material of wire	—	Silicium bronze	Copper	Copper

The electric current, as you know, is used for lighting buildings, driving machinery, propelling cars and trains.

* Lecture delivered on Aug. 29 at the meeting of the British Association at Johannesburg.

Digitized by Google

But throw away the notion, if any of you still have it, that electricity is a kind of gas, or oil, or fuel that is used up in these operations. The common expressions: buying electricity, consuming electric current, are most misleading, for just as much electricity flows away per minute—through the return conductor—from your electrically-lighted house as flows to it through the coming conductor. If, therefore, it were electricity that you had undertaken to pay for, you must have made a very bad bargain, because you do not retain the smallest portion of what you would have agreed to purchase. The electric current is like a butcher's cart carrying round meat—you no more consume current than you consume cart. It is not the vehicle, but what it leaves behind that the consumers buy—meat in the case of the butcher's cart, and energy in the case of the electric current. And exactly the same considerations apply to the distribution of power with air at 70lb. pressure per square inch to the thousands of rock drills on the Rand, to the distribution of power with water at 425lb. pressure per square inch down the shaft of the Rietfontein Mine, and at 750lb. pressure in the workshops of the Central South African Railways at Pretoria.

The energy conveyed with air, with electricity, or with water is made up of three factors: (1) the current, (2) the time during which it flows, and (3) the pressure under which it flows; while power depends on the current and the pressure only. Few words are used more vaguely than this one "power." Before starting for South Africa some of us gave someone a power of attorney; we came on a ship of 12,000 h.p.; the voyage did us a power of good; at the concert on board we sang of the power of love. In engineering, however, power has one very definite meaning—the rate of doing work, and a stream of air, of electricity, or of water exerts much power—that is, works rapidly—when it quickly loses pressure, or head. Quickly losing one's head, however, is not characteristic of large brain power, and the power exercised by those who sit in high places is often much in excess of their rate of doing any kind of work. When water has but a few feet of head, the quantity flowing over a waterwheel must be large if much work has to be done. But since the water usually comes to a low-pressure wheel along an open stream, and flows away again also along an open stream, no expense has to be incurred in laying down large pipes. If, however, it were necessary to distribute much power over considerable distances through a pipe conveying such low-pressure water, the pipe would not only have to be long, but of large cross-section, and, therefore, very bulky and costly. For example, this model is a full-size representation of the transmission of only 1 h.p. On the other hand, if the water possesses considerable head, the transmission pipe may be of small diameter. In this second model the three-cylinder pump produces a pressure of 425lb. per square inch, exactly the pressure used in the hydraulic transmission of power down the shaft of the Rietfontein Mine, and with that pressure less than four gallons of water flowing per minute through this ¾in. pipe gives as much power to this turbine as would be delivered by 825 gallons pouring per minute over this waterwheel 4ft. in diameter.

The water pressures in these two illustrations bear about the same proportion to one another as the electric pressure in the Lauffen-to-Frankfort transmission bears to the electric pressure usually maintained between the terminals of a lamp in Johannesburg. The value of using pressure water is grasped when you realise that at the Rietfontein Mine, by circulating about 85 gallons of water per minute at 425lb. pressure per square inch through a pipe 16 square inches in cross-section, not only is the circulating water all returned to the top of the mine, but, in addition, 144 gallons are pumped up per minute from a depth of 546ft. through a pipe 38½ square inches in cross-section. The water supplied by the London Hydraulic Power Company at 1,700ft. head, although not filtered, costs nearly four times as much per gallon as the filtered water furnished by the Metropolitan Water Board. In England dirty pressure water is a relatively costly commodity, sparkling drinking water a relatively cheap liquid. In Johannesburg, on the other hand, until quite recently the charge for drinking water was 10s. a gallon, plus 2s. 6d. a month for meter rent, or exactly 20 times the London rate—the temptation to drink other things in Johannesburg must have been very great. Now, since the establishment of the Rand Water Board, it is 6s. a thousand gallons, or still 10 times the London price, so that liquid with a head in London is still cheaper than plain drinking water here.

In the distribution of power, current and pressure are equally important. It is not merely because, even this month after a phenomenally dry season, about 5,000,000 gallons of water are rushing per minute over the Victoria Falls, but also because this water thunders down about 380ft. that makes these falls a potential source of power. The Howick Falls, near Pietermaritzburg, have nearly as much head as the Victoria Falls and twice as much as Niagara, while a siphon of soda water, when the gas is first pumped in, holds its head higher than any of the three. But, although in Johannesburg you probably pay a shilling for a siphon of soda water as an energy producer in man, it is not worth one ten-thousandth part of a penny as an energy producer in a turbine, since there is so little of it, only a pint and a half. Probably, like myself, you have heard vague comparisons made between the power of the Victoria and Niagara Falls. Now, what is the true comparison? The flow at Niagara varies at different times of the year from about 62 to 104 million gallons per minute. At the Victoria Falls the flow can be one-twelfth of the smaller number, for it is so now; and some authorities, well acquainted with the spot, say that at the end of another three months the flow will be only half of even that. The mean available drop at Niagara is about 160ft.; at the Victoria Falls about 380ft. Hence, while the *minimum* Niagara flow represents about 3,000,000 h.p., the *present* Victoria flow represents about 580,000 h.p., or only about one-fifth of the preceding. Further, if those who predict the flow of the Zambesi sinking to something like 2½ million gallons per minute in November are true prophets, the Victoria Falls will then only give out about 300,000 h.p., or, say, one-tenth of the *minimum* that Niagara produces. In all that precedes I have taken the full power of the direct drop in each case—that is, I have assumed in each case the intake to be close to the main drop, and I have deducted nothing for inefficiency of machinery.

Now, how exactly does the efficiency in the electric transmission of power depend on (1) the pressure, (2) the power transmitted, (3) the length of the transmission line, and (4) the resistance of the conductors composing it? The very simple approximate formula connects these quantities:

$$\left.\begin{matrix}\text{Percentage loss of power on the road}\end{matrix}\right\} = \frac{\text{Horse-power transmitted}}{3\ (\text{thousands of volts})^2} \times \text{miles} \times \left\{\begin{matrix}\text{Resistance per mile of all the conductors in parallel.}\end{matrix}\right.$$

This formula tells us that as long as the electric pressure is limited to some ten or eleven thousand volts—a pressure boldly used as early as 1897 by the Rand Central Electric Works, and at the Moodie Mines, near Barberton, but the one that is still the maximum sanctioned in Great Britain—it will not be possible, even with a pair of conductors of good copper, and each as thick as the one I hold in my hand—viz., ¾in. in diameter—to transmit more than about 6,000 h.p., or to transmit that power more than about 10 miles, without the loss on the road exceeding 10 per cent. The actual efficiency will, of course, be less than 90 per cent., since there will be losses also in the machinery at each end of the transmission system. If, however, the electric pressure be doubled—that is, raised to 20,000 volts—then through this pair of conductors (which are those kindly put up by the Transvaal Technical Institute to bring power from their dynamo-room to this hall, and which are not much more than one-fifth of the cross-section of the former, and, therefore, not much more than one-fifth of the cost, as regards copper) we can transmit 2,700 h.p. 23 miles, and still only lose 10 per cent. on the road.

Now Brakpan, where is the generating station of the Rand Central Electric Works, is almost exactly 23 miles from Johannesburg—six wires come thence to Johannesburg, three of which may be likened to the going conductor and three to the return in a two-wire system like this, also any three of those wires have a joint cross-section

Digitized by Google

rather larger than three times the cross-section of this. Hence with 20,000 volts about 8,000 h.p. could be sent to Johannesburg, from Brakpan, through the existing wires with only 10 per cent. loss on the road, or about 3,400 h.p., which is rather more than the entire maximum output of that generating station on any occasion last year, with only 4 per cent. loss. I should have liked to show you this experimentally, but Mr. Reunert, Principal Hele-Shaw, and Prof. Dobson, who since my arrival have so kindly put themselves to so much trouble to give expression to my wishes, might have thought me a little exigeant had I asked for a lecture hall big enough to include a transmission line from Brakpan. And so, instead of this pair of conductors connecting two places 23 miles apart, I am going to employ a pair of extremely fine wires, each less than one-hundredth of the diameter—that is, less than one ten-thousandth of the cross-section—so thin, in fact, that you cannot see them. Switch on the current, 100 lamps glow. Now think of a wall of lamps 10 times as high, then 10 times as wide, and then six times as big as all that, and you will have 2,700 h.p. And that is the power which, put into this pair of wires 23 miles away, say at Brakpan, with this pressure of 20,000 volts, will cause about 2,400 h.p. to come out at Johannesburg.

I drew your attention to the fact that in 1888 the male population of Johannesburg was 2,000 By 1896, according to the census taken that year, it had grown to 32,387. Now, curiously enough, in 1897 two transmissions were arranged for at 33,000 volts—the one at Crofton, California, and the other at Redlands, California. And no pressure higher than that used on the Lauffen-Frankfort transmission seems to have preceded this 33,000 volts anywhere in the world. Indeed, it would almost appear as if electrical engineers were waiting to use a higher pressure than 25,000 volts until the publication of the census of Johannesburg. In 1898 the highest working pressure in the world was 40,000 volts for a 34-mile transmission at Provo, in Utah, and the male white population in Johannesburg was also 40,000. Then came the war, and volts beat white man, for, according to the census of last year, while the white male population was 52,106, there were several examples of transmissions at 60,000 volts, as seen from Table II. But with the influx of the white members of the British Association doubtless the tide will turn, white man will make a spurt and catch up electric pressure, and in this respect, at any rate, the Witwatersrand will become a white man's country.

TABLE II.

Year	From	To	Country.	Transmission distance in miles.	Horse-power transmitted	Pressure at transmission end in volts.
1897	Crofton	—	California	—	—	33,000
,,	Redlands	—	,,	—	—	,,
	—	Bangalore	India	92	4,300	35,000
1898	Provo	—	Utah	32	—	40,000
—	Gromo	Nembro	Lombardy	22	3 300	,,
—	Logan	Salt Lake City	Utah	150	2,600	,,
—	Canyon Ferry	Butte	Missouri	70	5,700	50,000
—	Shawinigan	Montreal	Canada	90	15,000	,,
—	Moutiers	Lyons	France	112	—	57,600
—	Spokane	Washington	—	100	3,000	60,000
—	—	Guanaguato	Mexico	104	4,000	,,
—	Electra	St. Francisco	California	147	10 000	,,
—	Colegate	Stockton	,,	218	5,000	,,

Indeed, not only have various successful 60,000-volt transmission schemes been carried out, but the Kern River Power Company in California are constructing one for transmitting 4,020 h.p. over 110 miles at 67,500 volts. Transmission at 67,500 volts over 110 miles. Why, when the new railway—Brakpan to Witbank—is completed, 110 miles will be 20 more than will separate the Rand from the coalfields at Witbank—fields that produce such good coal that the Central South African Railways have contracted to purchase 84,000 tons during this year at 6s. per ton at the pit's mouth. Now, at a pressure of 67,500 volts, these two small wires could, without warming, bring about 9,000 h.p. from Witbank and deliver 7,600 of it to the Rand. Or if six wires were used like those now employed by the Rand Central Electric Works, then, at 67,500 volts, 9,000 h.p. might be put in at Witbank and only 5 per cent. lost on the road—that is, about 8,950 h.p. delivered on the Rand. But the insulators would have to be placed much farther apart than on the existing Rand posts to prevent the starting of a brush discharge between the wires—a subject to which I will return. You will now grasp why in 1895—10 years ago—it was a bold and pioneering policy to equip the Rand Central Works for 10,000 volts, and to use 13,000 volts during times of full load, but why in 1905 the recommendation of some advisers to distribute power at only 10,000 volts to the proposed sub-stations of the contemplated 57 miles of electrified railways—Springs to Randfontein—is most retrograde of those advisers to the railway.

In 1879 a firm of electrical contractors, well known then, and equally well known now, told me that they had been asked to tender for the construction of an electric transmission system to convey a comparatively small amount of power 10 miles. But since they considered that they could not possibly hope to deliver more than half, while, in practice, they feared that they would only succeed in delivering much less, the proposal had to be ranked with the exploits of Gulliver and Baron Munchausen, and so even that firm declined to tender. To-day, 26 years later, electric power is, from an engineering and from a business point of view, being successfully transmitted 232 miles—nearly as far as some of you took 15 hours the night before last in being transmitted from Ladysmith. Now, how are these electric pressures of ten, twenty, thirty, forty, fifty, or sixty thousand volts produced? Why, by means of the alternate-current transformer, which does for electric power exactly what the lever does for mechanical power. Exert a small force through a long distance at the long end of a lever, and you have a large force exerted through a short distance at the short end. Apply a small electric pressure with a large current at one side of a transformer, and you have a large pressure with a small current at the other. But there are no moving parts, therefore the arrangement is called a "static transformer." It requires no adjustment from day-to-day, therefore it may be kept entirely immersed in oil to improve its insulation.

Such statical transformers I used to step up the pressure from 100 to 20,000 volts at the transmitting end, and to step down the pressure from 20,000 to 100 volts at the lamp end, in the last experiment. Everything looked quite harmless until I intentionally brought the transmission wires into contact. So does the transformer, immersed in a huge cylinder of oil, now projected on the screen, although it regularly produces 60,000 volts, and can supply 1,000 h.p. at that pressure. So does the water-cooled transformer, the interior of which is seen in an X-ray picture, to the right, and the exterior to the left; although it can supply 2,000 kw.—that is, 2,700 h.p.—and the size of which is realised by comparing it with the tiny transformer by its side—the size of the one which I have on this table. Sixty thousand volts—well, what of it? some of you may say. It cannot start a discharge between even sharp needle points separated by a greater distance than about 6in., and some of you have produced such a spark with an electrical machine—I am producing such a one now. But each time that a spark passes between the terminals of the electrical machine the pressure is relieved, so no arc is maintained. Bring, however, the terminals of that transformer within 6in. of one another and a roaring arc of 2,700 h.p. will be kept up, dealing destruction around. Let me show you a spark started with a 70,000-volt transformer when supplied with only 1 h.p. What a banging is produced. Now, picture to yourselves what would be the result if the power were not of one but of 2,700 horses, such as that transformer can furnish. The photographs show the sort of discharge that may occur over the surface of an insulator 1ft. high—such as is used on a high-voltage transmission line—when the testing voltage is 80,000 in this case and 105,000 in that, and when there is plenty of power to maintain the arc. It is veritable lightning, not a mere flash, but a continued flame. And the sort of insulator that is used in practice for a 70,000-volt transmission is realised by looking at the specimens, which are only intended for 10,000 volts. There is nothing new in high voltage by itself—it existed

Digitized by Google

in the period of the frictional electrical machine 50 years ago, but it was associated with only a very small current; next, dating from the development of the dynamo, came the low-voltage large-current period; and now we have entered on a third era, the high-pressure moderate-current period—that is, the period of high pressure combined with horse-power.

Next I come to a very important question, and one that merits far more consideration than it has yet received. There are two kinds of electric current—direct current and alternating current. Direct current is like a continuously flowing stream of water, such as, for example, the one that flowed through this pipe and drove this turbine. Alternating current, on the contrary, is like this band, which, although swinging backwards and forwards, also turns a wheel in one direction at the other end. Now, which kind of electric current should be used for the distribution of power over *long distances?* Practically, every electrical engineer will at once reply: alternating, of course. Well I am going to preach heresy. The alternating current has undoubtedly the great advantage that a motor can be constructed with no rubbing electric contacts, every wire may be permanently soldered in position—a condition of considerable importance in dusty places like mines. Here is such a motor—the first polyphase motor ever sent from America to Europe, the first ever seen in Great Britain, constructed 17 years ago by Tesla with his own hands, when he was too poor to employ a workman.

Another advantage possessed by an alternating current is that an alternating-current dynamo can be constructed to produce a large horse-power at a high voltage; and, further, as we have already seen, this alternating voltage can be transformed into a still higher one without the use of moving machinery. This is one of the five largest dynamos in the world. Its size you can better estimate by looking at the ring on end, now projected to the left. The latter is the stationary portion of a 5,000-h.p. horizontal-shaft dynamo, whereas the photograph to the right is of a vertical-shaft machine of double that power—viz., a dynamo that can develop 10,000 h.p. at a pressure of 11,000 volts. Fifteen years ago, Ferranti—the Brunel of electricity—spent a mint of money constructing some of the parts of a 10,000-h.p, 10,000-volt alternator, which were, however, never put together. This dynamo, with its four sisters, stands complete in the Canadian Niagara power-house, and the tests already made show that its efficiency reaches the extremely high value of 98·2 per cent.—that is, 1·8 per cent. of the power developed is sufficient to cover all losses. Ferranti's dream is more than realised, and the old story is repeated. We break up the pioneer leviathan, the "Great Eastern" steamship, as a great unwieldly giant very weak in its knees, we build the "Baltic," a third as large again, and with twice the engine power. Without any transformation at all these dynamos will economically drive machines some miles away, and with the pressure transformed up from 11,000 to 60,000 volts power will be distributed in Toronto, 85 miles away from the falls. Contrasted with this, no single large *direct*-current machine has ever been constructed to generate more than about 3,500 volts, and no means is known for efficiently converting a direct-current voltage into a higher or a lower one without the use of moving machinery.

So far, then, my case seems weak! The advantages of using great electric pressures we have seen. Are there any disadvantages? This is a disadvantage, the risk of piercing the insulation! See how thick the insulating material has to be on cables, how far apart the conductors have to be placed, even when the cable is intended for only 10,000 volts. But does this consideration supply any argument for or against the use of one kind of current rather than the other? Small current and high pressure must be used for the economical transmission of power over long distances, whether the current be alternating or direct, I agree, but, ladies and gentlemen of the jury, I submit that, while from the point of view of economic transmission 60,000 volts alternating means exactly the same as 60,000 volts direct, from the point of breakdown of the insulation, 60,000 volts alternating is as bad as 85,000 volts direct—indeed, may be worse than 100,000 volts direct. For an alternating current consists of waves like the waves of the sea. In a storm the waves may be running mountains high, and yet the average depth of the sea remains the same as in a calm. But what does it benefit the poor passengers, when tossed helplessly backwards and forwards in their berths, and feebly calling "Steward," to be assured that, although the waves be peaked and the maximum elevation large, the square root of the mean square of the amplitude of oscillation is quite consistent with perfect internal tranquility? And so feels the poor insulating material—the mean electric pressure may not be very large, and yet the crests of the waves may be so high, and the troughs so low, that its strength cannot stand the electric tossing. Each of those waves of electric pressure on the diagram gives the same reading on a voltmeter, but the peaked one has far more destructive action than the flat-topped one.

But there are other disadvantages in the use of alternating current. This coil of wire represents one of the conductors which, when unwound, might join two places—the one where glow lamps, for example, have to be made to incandesce, and the other, where is the water power which drives the dynamo that generates the current. If a *direct* pressure of 100 volts be applied at one end of the system, the lamps at the other end glow brightly, as you see; whereas, if now, I apply an *alternating* pressure, although of exactly the same value, the lamps are quite dull. The explanation of this striking difference is that, in such a case, only a fraction of the *alternating* pressure is used in making the lamps glow, the remainder being employed in maintaining a rapidly reversing magnetic field. This magnetic effect—this self-inductive effect, as it is called—is small, if the going and return conductors be straight, short, and near together. But, if the distance over which the power is to be transmitted be long, the wires obviously cannot be short, and, if to obtain economy high electric pressure be used, the wires cannot be put very near together, since that would lead to a brush discharge through the air from one conductor to the other, producing leakage. Indeed, the minimum distance that must separate the conductors has to be increased very rapidly with the pressure. Table III. gives this minimum distance for conductors $\frac{1}{10}$in., $\frac{2}{10}$in., and $\frac{4}{10}$in. diameter respectively. It is to be noticed that increasing the thickness of the wire greatly diminishes this minimum. For instance, at 80,000 volts, doubling the thickness of the wire from $\frac{1}{8}$in. to $\frac{2}{8}$in. diminishes the minimum distance from 6½ft. to 13½in. It must, of course, be remembered that these are minimum distances, and that the distances apart at which the wires have actually to be fixed in practice are much greater.

TABLE III.—Johannesburg. Elevation, 5,689ft. January, 1905. Barometer, 24·3in. Temperature, 91·5deg. F. Minimum distance that must separate two parallel wires to prevent the starting of a brush discharge.

Electric pressure in volts between wires.	Diameter of wires in inches. $\frac{1}{10}$	$\frac{2}{10}$	$\frac{4}{10}$
40,000	8·8in.	—	—
50,000	32·2in.	—	—
60,000	9·9ft.	14·7in.	—
70,000	35·7ft.	33·8in.	—
80,000	—	6·5ft.	13·6in.
90,000	—	—	23·0in.
100,000	—	—	38·0in.

But that is not the whole indictment against the use of alternating current for *long-distance* transmission. Leakage from wire to wire can be rendered small, but still, if the current be alternating, it always flows along the wires, even if all the apparatus at the distant end be entirely disconnected from them. Let me show you this: I apply a direct pressure of 100 volts, and no current enters the transmission line, for it is well insulated along its length and at its ends. I apply instead an alternating pressure of the same value, without making any other change, and you observe a very perceptible current. The very first thing that struck Ferranti when he commenced transmitting power with alternating current at 10,000 volts pressure from Deptford to London was that the current flowing into the system at Deptford was as large during the daytime, when practically no lamps were turned on in London, as during the evening, when many lamps were glowing. And in the case of the 150 miles transmission at 50,000 volts by the Bay Counties Power Company, in California, it was found that to charge

Digitized by Google

even the aerial lines as a condenser required 40 amperes, so that the current flowing into the system remained practically unchanged when the useful load was decreased from several thousand horse-power down to nought.

(To be continued.)

ELECTRICAL CONTROL OF BULKHEAD DOORS.

On the new warships of the American navy there is installed what is known as the "Long Arm" system of electrically-operated bulkhead doors and hatches. The heart of the system is the central emergency station from which the doors and hatch plates may be closed by starting the motors with which they are equipped. The working parts of the station are contained in a two-part watertight case secured to the side wall of the pilot-house or other convenient place above decks. The apparatus of the station consists of three parts: (1) the mechanism for controlling the circuits running to each door or hatch gear

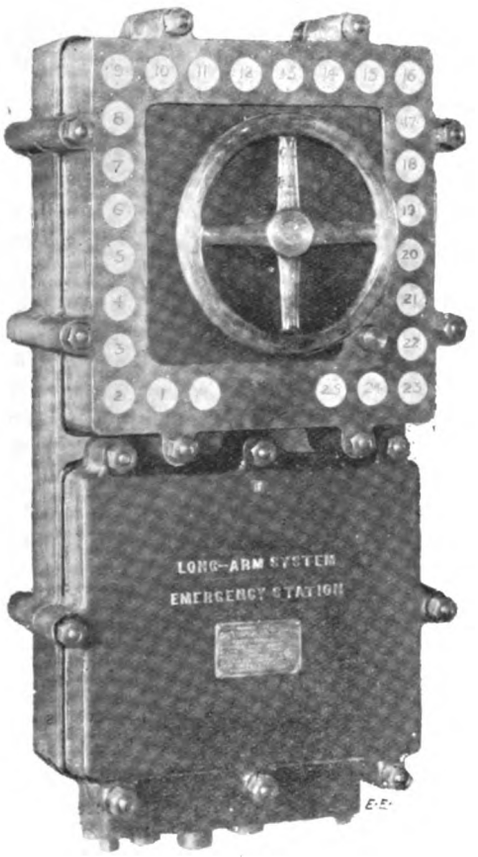

FIG. 1.—Emergency Switch Operating Gear.

for closing the same; (2) the lamps which indicate the closure of each door or hatch; (3) the fuse-box in which each entering wire is supplied with its proper fuse. The accompanying photograph shows the emergency station closed and with the protective covering removed.

To operate the emergency station, the officer in charge releases a hand-wheel (Fig. 1), which, in turn, releases a gear driven by a powerful spring (Fig. 2) and controlled by a suitable the escapement. This gearing closes the circuits for operating emergency switches located in the controller of each door and hatch gear. In performing this function the gearing does not start all the motors at the same instant, for the reason that this would demand a large supply of current from the ship's generators. It starts them one after the other at about a three-second interval, so that it rarely happens that more than four motors are in operation at any one time, although the entire closure of 24 doors and hatch gears controlled from one emergency station may be accomplished normally in about a minute and a quarter. When, however, an extremely quick closing of all doors is required, this time can be reduced to 30 seconds for 24 doors by simply using the hand on the wheel of the emergency station to hurry it; and this action does not alter the closing speed of any individual door or hatch. As each bulkhead door reaches its watertight seat, it automatically closes a circuit running to the emergency station, there connected with one of the small incandescent lamps. Transparent discs over these lamps bear numbers corresponding to the numbers of the various doors under control. The officer in charge, by pressing a button, can cause the indicator lamp of every closed door and hatch to glow, thereby assuring himself of the successful operation of the emergency action. If any door is prevented from closing by obstructions left in its path, this fact at once is apparent to the officer in charge, and no time need be lost in reaching the scene of the difficulty. The emergency station contains but one spring which furnishes the entire power for operating the device. This spring is of the helical type and of ample strength for the work it is called upon to do.

Although the experience of hard sea service has shown that the emergency station of the "Long Arm" system can

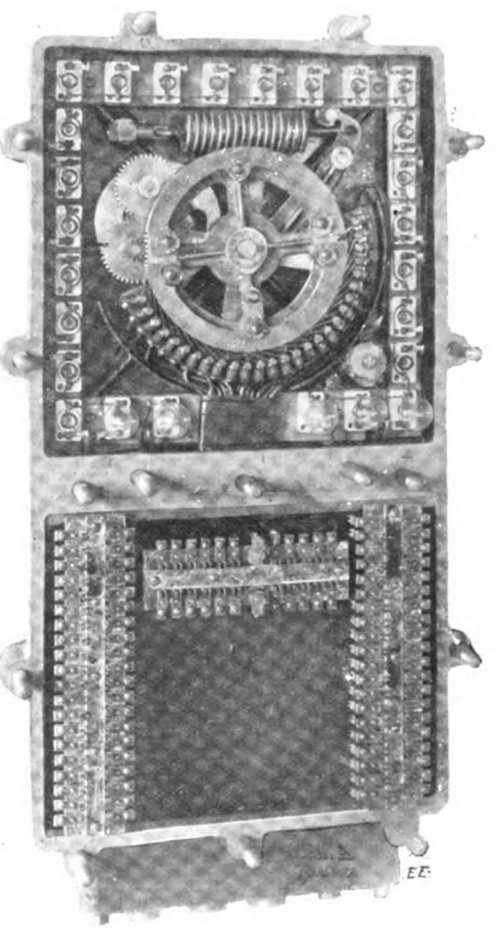

FIG. 2.—The Switchgear, with cover removed to show mechanism.

be depended upon for successful operation at all times, to guard against the possibility of failure, the mechanism can be actuated at any time by turning the hand-wheel located in front of the case should the station fail to act automatically by the power of the spring when released. During any emergency period a red indicator lamp glows continuously, so that a casual glance at the emergency station shows at once whether the emergency is "on" or "off." After a danger period is passed, and it is desired to again establish normal conditions below, the emergency may be thrown off by a hand reversal of the same operating device which is used to throw it on, so that the mechanism when not in use is always set ready to operate and always available in time of need.

TANTALUM LAMPS.—A price-sheet just issued by Messrs. Siemens Bros. and Co., Limited, York Mansion, Westminster, S.W., deals with tantalum electric glow lamps for the following voltages—viz., 50, 55, 60, 65, 75, 100, 105, 110, 115, 120, and 125—and candle-powers ranging from 10 to 25. The efficiency claimed is very high in comparison with the ordinary type of glow lamp, and is shown to more than compensate for the greater first cost.

THE EXHIBITION.

Some of us, unfortunately, are able to speak from personal knowledge of the first great international exhibition held in 1851—a lifetime since. Electrical apparatus was not unrepresented then, but that which created wonder in 1851 has long since passed into the limbo of the forgotten. The decade following was an active one in electrical investigation, but in that great exhibition in the early sixties nothing hardly was exhibited which has persisted. In fact, not till the Paris Exhibition of 1878 did we really enter into what may be called the electrical era, and then only a dawn which revealed little or nothing of what would happen in 1881. The exhibition in that year—1881—was also held in Paris, and proved that the dawn of 1878 would usher in a brilliant and world-changing era. The idea of international exhibitions was originally a double one—ostensibly for education, practically for advertisement. The educational fallacy died a lingering death; indeed, sometimes it seems only moribund, and a whisper is heard that the aims of exhibitions are still mainly educational. That is an impossibility. Exhibitions always have been and always will be mainly for business purposes, and we welcome all the more heartily the exhibition to be opened at Olympia next Monday because its promoters are honest. We welcome it also because they are clear-sighted, earnest, painstaking, and energetic. They saw what was required, and they have not spared themselves in order to get it. In what may be termed the transition period—that is, the time between State-aided exhibitions and the really commercial thing—there have been a number of so-called exhibitions which we always considered were valueless for any good purpose. The present exhibition we recognise as the "real thing"—organised by business men for business purposes, and not run with State money for the private glorification of half a dozen officials. The general public, even with all the literature at its command, does not know and has not the faintest conception of the ramifications of electricity. The expansion in the use of electrical apparatus since 1881 is to the uninitiated one of the greatest wonders that has ever happened in the history of this world. The adoption of steam was slow compared with it. Electrical energy is being used over so widely a diversified field that its uses can hardly be enumerated, and it seems difficult to imagine where its utility will cease. This exhibition, if only its promoters succeed as well as they hope and ought to succeed in inducing the public to visit, will do more good to the industry than all the exhibitions that have gone before, for applications of the wizard power will be seen that will appeal as well to the meanest as to the most educated "imaginations." We well remember the scorn with which Sir W. H. Preece's statement that the electric lamp was the poor man's light was met. He, when he said this, saw far ahead, and, though the prophecy is not yet completely realised, a good many thinkers have recognised its underlying truth. When Volk, at Brighton, built an electric motor carriage and a little railway, few realised the development that would ensue within twenty years of that date. At this moment scarcely any proposition put forward by prominent electrical engineers concerning power distribution for traction or other purposes would meet with a single doubter. Indeed, prophets in increasing numbers are indicating that steam-engines will ere long be entirely superseded by electrical apparatus. All the newest applications and all the newest developments will be seen at Olympia, though it may be expected that the heavier machinery for power purposes will have to be taken some-

Digitized by Google

what on trust. The greatest display will probably be of all that class of apparatus which will appeal to the general householder, and which will show him a hundred directions in which he may utilise current and introduce improvements. It is to be noticed that an excellent series of lectures descriptive of special phases of electrical work will be delivered by experts. These lectures should appeal to the public desirous of becoming acquainted with the subject. We sincerely wish the exhibition success.

STREET-LIGHTING.

The Croydon street-lighting report and the answer to the same by the local gas companies afford both useful and amusing reading. The later effusion clearly shows that the gas companies have acknowledged themselves beaten on their favourite ground, which is that of supplying the cheaper light. The flame arc lamps have effected this change of front, and now the companies decry the value of photometric tests. The alternatives offered are two: one, to compare the total cost of lighting a mile of street irrespective of the light provided; and the other is "a man's own test—that is to say, for a person to himself ascertain which illuminant is the best to see by." This quotation from the speech of a strong anti-electric advocate is valuable or otherwise according to what is read into it. Literally it is as valuable as a "woman's own test," in which opinions rather than facts rule the decision. The gas companies' figure as to the cost per mile of street is equally valueless, as it makes no distinction between the different class of the streets or the lighting provided. On this standard the Corporation of Croydon will be well advised to discard both gas and electric lighting, as luminous paint applied to the existing lamp-posts will cost much less than either illuminant, and will indicate the directions of the roads quite as well as some of the existing gas lamps. The final remarks as to the profits to be made by the Corporation hint that street-lighting is being supplied at a loss. This is denied by the Corporation, but we know of several cases where the gas authorities offer an unprofitable price to secure street-lighting. In business operations such offers are as well understood as is the present proposal by the Croydon Gas Company for experimentally lighting certain streets. We hope these experiments will be made, and that accurate records of cost and illumination will be kept from these and similar experiments with the latest forms of electric lighting. Then there will be no need for lobby work to decide as to the method by which the Croydon street-lighting shall be improved.

THE OLYMPIA ELECTRICAL EXHIBITION.

The arrangements in connection with the approaching exhibition are now nearing completion, and it is evident that, both from the magnitude and representative character of the exhibits, the exhibition will do credit to the industry it represents, and doubtless the result will be beneficial to the whole profession and to those indirectly connected with electrical engineering. The president of the exhibition, Sir Wm Preece, being unfortunately abroad, the Lord Mayor and Sheriffs, who will attend in state for the opening ceremony, will be welcomed at the entrance by the chairman of the executive committee, Mr. E Cunliffe-Owen, together with the other members of the executive; the City dignitaries will then make a brief inspection of the exhibits, and the Lord Mayor will then in a few words declare the exhibition open. The inaugural lunch will follow, to which the Lord Mayors of York, Liverpool, Manchester, and Birmingham, the Mayors of the metropolitan boroughs, and a large and distinguished company have been invited. The management are leaving no stone unturned to ensure everything being in readiness by the time of the opening, and they are being well backed up by the exhibitors, who in many cases find it necessary to work night and day in consequence of the elaborate preparations necessary in the way of foundations. Of the exhibits themselves we shall, of course, have a good deal to say in succeeding issues.

The syllabus of lectures arranged by the Institution of Electrical Engineers is as follows: Tuesday, Sept. 26, open; Friday, Sept. 29, "Wireless Telegraphy," by W. Duddell, member of Council I.E.E.; Tuesday, Oct. 3, "Development of the Use of Electric Motors," by Colonel Crompton, past-president I.E.E., M.I.C.E.; Friday, Oct. 6, "Domestic Lighting," by J. Swinburne, past-president I.E.E, M I C.E.; Tuesday, Oct. 10, "Meters," by S. Z. de Ferranti, vice-president I.E.E., M.I C E.; Friday, Oct. 13, "Telegraphy" (ordinary), by A. Martin; Tuesday, Oct. 17, "Arc Lighting," by Mrs. Ayrton, M I.E.E; Friday, Oct. 20, "Telephones," by F. Gill, member of Council I.E.E. In connection with the cooking utensil competitions, the executive committee have decided to allot the sum of £100 as prizes, to be appointed as under: for the best group of cooking apparatus on exhibit, first prize £50, second prize £20; for the best single piece of cooking apparatus on exhibit, first prize £20, second prize £10.

The number of firms who lay themselves out specially for this class of business is necessarily limited, but we are informed that the entries comprise the best makers, and that some novelties may be expected which will be of considerable interest. A portion of the building has been specially set apart as a kitchen, where an experienced lady lecturer will give practical demonstrations of cooking by electricity, ample accommodation being provided for the general public to witness the proceedings. This will undoubtedly form one of the most interesting features of the exhibition.

In the galleries (to which special access has been provided by means of a lift on each side of the centre of the ground floor, which has been erected as a working exhibit by the Easton Lift Company) will be shown the General Post Office exhibit, the Marconi stand, and a large number of interesting trade exhibits, including several rooms which will be wholly devoted to a display of fittings suitable for drawing-room, dining-room, etc. The Guards' bands will also perform from a specially erected stand in the centre of one of the galleries.

AUSTRALIAN TRADE MARKS.

We learn from Messrs. W. P. Thompson and Co., patent agents, Liverpool, that the new Australian Trade Marks Bill introduced by the Commonwealth Government is in many important respects similar to the new English trade mark law, amended slightly to suit Australian institutions. There are, however, the following special points in it. The proprietor of a trade mark registered in any State of the Union before the commencement of this Act is entitled to have his mark registered for the whole of Australia, but subject to the rights of other users or proprietors of a similar mark in any of the other States of the Union, and provided it could at the time when the Act came into force have been lawfully registered in the Australian State in which the trade mark was then registered and in use. If a mark has been publicly used by more than three persons or firms in any one State of the Union as a mark in connection with similar goods, it shall be held to be common to the trade, and, therefore, not registrable. There is a special section on trade union marks, by which any trade union of workmen or employers registered under any law of the Commonwealth or of any State may register a mark as a trade union mark, only to be used by members of that trade union, and any person wilfully infringing the same is liable to a penalty of £50. A clause is inserted by which Australia can enter the International Union for the protection of patents and trade marks. The measure appears to have been drafted upon comprehensive lines, and it is expected to be passed this session practically in its present form, as it meets with general approval.

ELECTROMOTORS LIMITED NEW BRUSH-HOLDER

In spite of the large number of brush-holders which have been introduced since carbon brushes have been in vogue, Electromotors Limited have succeeded in designing a new patent brush-holder which contains several novel and useful features. This holder we are illustrating herewith, as the details will be of

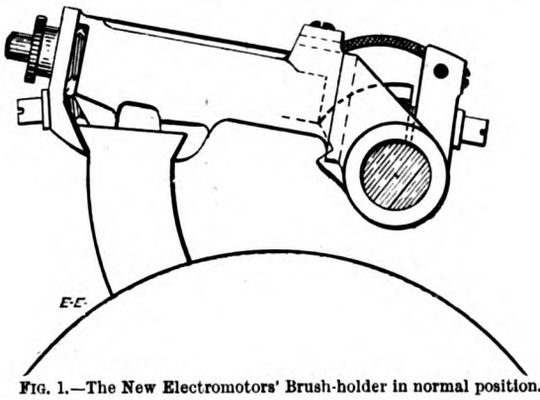

FIG. 1.—The New Electromotors' Brush-holder in normal position.

interest to all electrical engineers. We show the holder in Fig. 1 in its normal working condition with a new brush in position on the commutator. In Fig. 2 the brush-holder is withdrawn from the commutator, and a few more details of its construction are indicated. The detailed parts of the holder can be seen in Fig. 4, which is a photograph of the same arranged to show the position they occupy in the completed

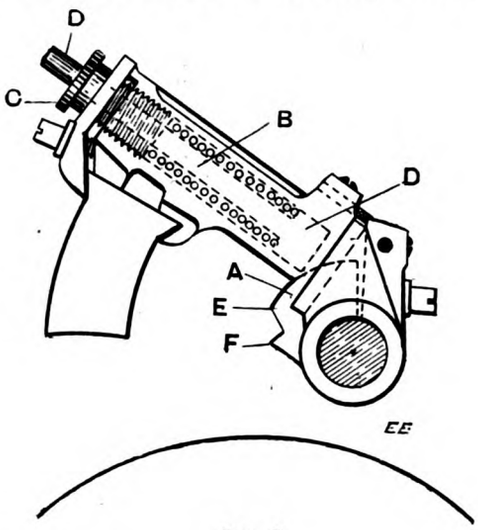

FIG. 2.

holder. Fig. 3 shows how much a brush can be worn down before it needs to be replaced. Following the construction through in detail, it will be seen that a fixed cam, A, is fastened on to the brush handle spindle by means of a screw. The arm of the brush-holder, which revolves radially round the spindle, contains a cartridge-shaped portion, B, in which there is a plunger, which is forced by a spring against the face of this

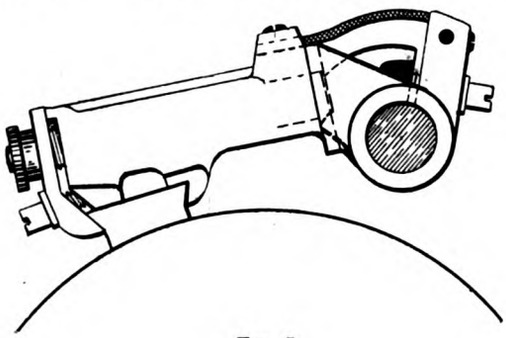

FIG. 3.

cam. This spring is worked in compression, in contradistinction to the majority of brush-holder springs now in use. Also the spring is completely enclosed within the brush arm instead of being below the arm, and in a position which may involve the parts of the spring falling against the commutator should it, or its attachments, break. The compression on this spring, which regulates the pressure of the carbon brush on the commutator, is adjusted by means of the milled head of the hollow screw, C, which also forms a guide for the stem of the plunger, D. In the normal working position and throughout the range of motion equivalent to the wear of the brush, the plunger, D, is bearing against the corner, E, of the cam. It moves slowly down this as the brush wears, and finally reaches the stop, F, which acts as a lock and prevents the brush holder from touching the com-

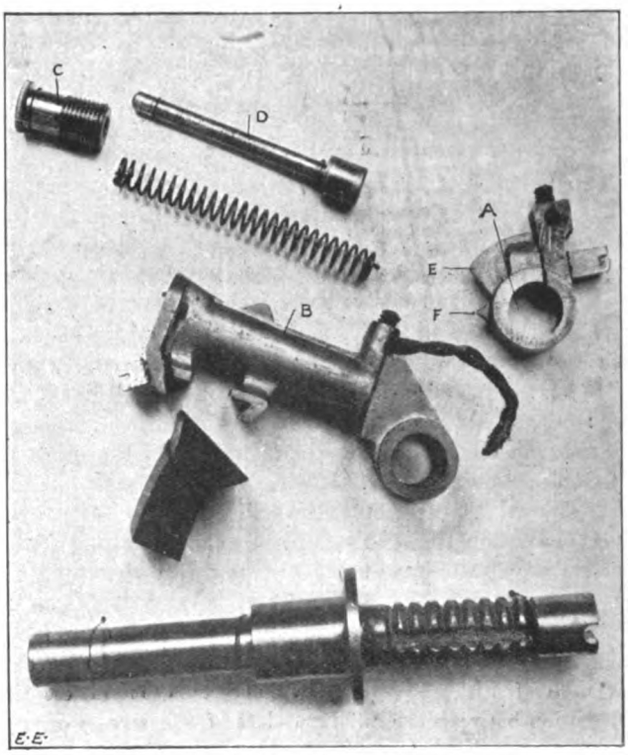

FIG. 4.—The Component Parts of the New Brush-holder.

mutator. This is the valuable feature of the design. If pulled pulled back from the commutator, the brush-holder revolving round the spindle brings the plunger over the point, E, of the cam, and then there is no tendency for it to move back again. This rounded portion of the cam thus holds the brush in the off position, but there is no locking device to be felt for

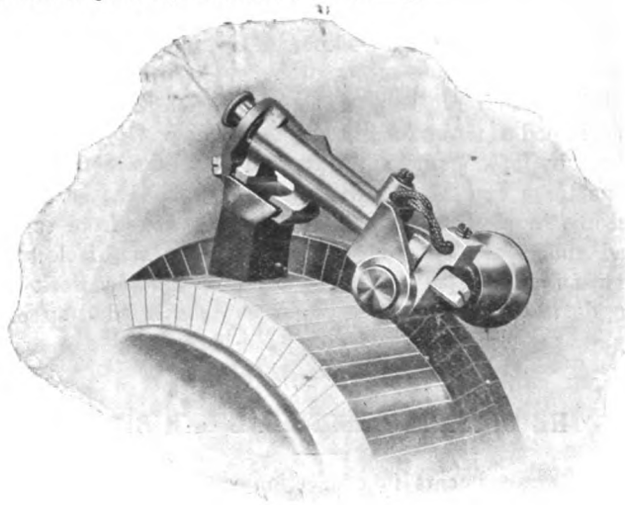

FIG. 5.—View of the Complete Holder.

when the brush has again to be put on to the commutator. It is sufficient instead to move the brush forward until the plunger slides over the corner, E, and brings the holder into effective use. This is a valuable feature where motors have to be handled by unskilled labour, as brush-holders are frequently damaged by being forced on without an attempt to release the locking-off device. It will be seen that the carbon brush is gripped in an efficient clamp by a single screw which is situated near the milled head, which adjusts the pressure of the brush. This is also convenient for an enclosed type of motor, and is superior to the arrangement which involves the pressure adjusting being done from the back and the clamping of the brush from the front of the holder. The carbon brush is so designed that its position on the commutator is not varied by wear. Finally, the working parts of the brush-holders are few, and they are entirely

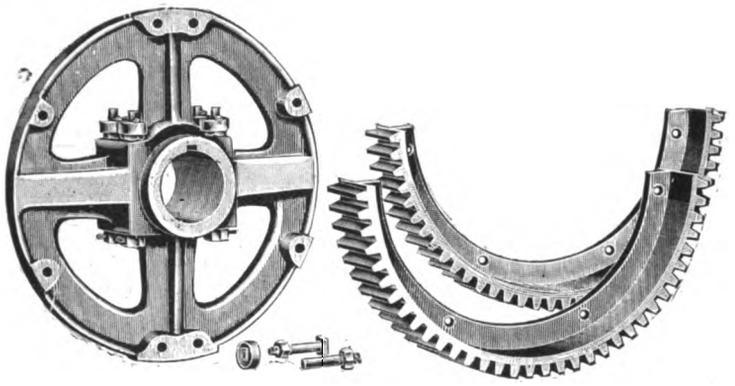
Digitized by Google

enclosed and protected from dust, which two points should ensure a freedom from the troubles often found in the sliding carbon type of brush-holder. There are other advantages in this brush-holder which will commend themselves to those responsible for the upkeep of continuous-current motors, which will be readily seen from the accompanying illustrations. Amongst these is the fact that the holder will work without adjusting or attention for a period equal to the whole life of the carbon brush. Should it be left too long without attention, the brush-holder will not come down on to the commutator and score the same, as too frequently happens with other holders. The firm are using this brush-holder on all their motors, and are showing the same on the "Electromotors'" stands at the Olympia Exhibition next week. The holders are protected by patents in foreign countries as well as in Great Britain.

TRADE NOTICES AND NOVELTIES

Gear Wheels with Renewable Rims.

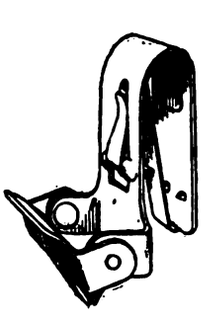
The Electrical Company, of 121-125, Charing Cross-road, W.C., are putting on the market a line of gear wheels with renewable rims, which should be found extremely serviceable in electric traction. As will be found from the illustration below, the rim is made in two halves, which are securely bolted to the hub of the wheel. This hub can either be one casting pressed upon the axle, or it can also be in halves as shown in the illustration. In the latter case the joints in the rim are placed at an angle 90 deg. apart from the joints in the hub. By using the split gear rims the time required to change the wheel is very much reduced; the makers also claim a considerable increase in the strength, thus, whereas the average tensile strength of cast steel is 28 to 30 tons per square inch, the rims can be made of a much stronger material. For this purpose first-class Siemens-Martin steel with a tensile strength of from 38 to 46 tons per square inch is used. It is evident from this that the rims and teeth must be far superior to those of ordinary cast steel. Again, when replacing the cost of a rim itself is considerably lower than that of a complete cast-steel gear wheel, which allows a considerable financial saving from the use of renewable rims. The firm have offered to let us have samples of these wheels in our office to try, but we have not accepted the same for want of testing facilities and space. We feel sure, however, that tramway engineers will receive equally courteous offers from the company.



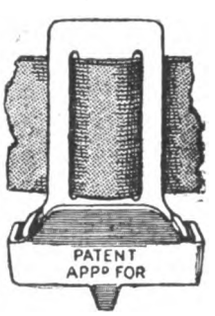
Gear Wheels with Renewable Rims.

A Useful Tool Carrier.

We have had brought to our notice an ingenious plier and tool carrier which is being introduced by Messrs. Alfred Castell, Gibb, and Co., 247, St. John-street, London, E.C. This little device not only carries the tool, but also guards it from accidental loss. In other words, any tool entrusted to the "Ideal" carrier is securely locked in position, but can be instantly released when required for use. Wiremen, especially, should welcome this carrier, which will thus enable them to have their pliers ever ready to hand. Accompanying are illustrations of two of the several patterns made, one being designed for use with a belt, and the other for hooking on to the pants of the wearer.



Tool Carrier for Fixing Direct.



Tool Carrier for Belt.

Switchboard Instruments.

Messrs. Siemens Bros. and Co., Limited, York-mansions, London, S.W., have just issued a comprehensive price list of their switchboard instruments and accessories. This list is divided into five parts, comprising electromagnetic instruments, moving-coil instruments, Ferraris instruments, instrument transformers, and various special instruments and accessories respectively. The electromagnetic instruments are intended for general switchboard use. They are practically dead beat. The moving-coil instruments are, of course, intended for use with continuous current only, and the types comprise flush cases and watertight cases, edgewise dials, and specially large circular dials. A large range of shunts for use with the ammeters is also listed. Other special instruments of the moving-coil type are combined ammeters and voltmeters (see the accompanying illustration Fig. 1) for searchlights and automobiles, and wattmeters built on the dynamometer principle. Ferraris instruments, for alternating currents only, are built on the well-known rotary field principle, and ammeters, voltmeters, and wattmeters are listed in a large number of sub-types, as is also the case with the moving-coil instruments. A special feature is made of wattmeters for three-phase currents with branches unequally loaded. A special type of universal station instrument is shown with dial 21in. in diameter, for reading station volts, amperes, and kilowatts. Current and voltage transformers are listed in a variety of types for working pressures from 1,000 to 50,000 volts. The special instruments comprise current-directing indicators, earth indicators, ohm-meters, voltage and power relays, and a safety relay for breakages of three-phase overhead lines. The last-mentioned device, the connections to which are shown in Fig. 2 herewith, is used in connection with high-tension three-phase installations for the purpose of completely breaking the circuit if a conductor falls at any distant point. This is achieved by the closing of the local circuit of an automatic cut-out which breaks the high-tension circuit feeding the fallen wire. The device has the advantage that it only comes into operation through the breaking of a conductor, and not under any other conditions, as, for example, by the reduction of the load below a specified point, or through unequal balancing (up to about 30 per cent.) of the load of the three separate conductors. It is similar in construction to the Ferraris measuring instruments, and consists essentially of a ring-shaped core carrying the coils, and whose three poles are in part provided with the necessary short-circuited windings; also a light revolving metal drum, on the axis of which a contact lever is secured for closing the exciting circuit. The windings round the three pole-pieces are connected to the mains through three current transformers. The operation

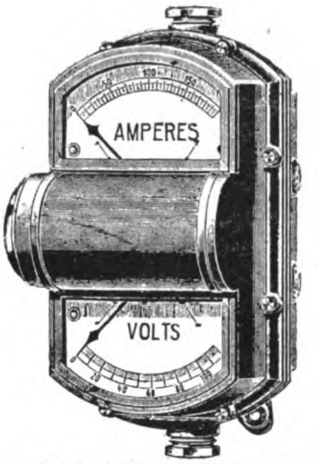


Fig 1.—Combination Instruments.

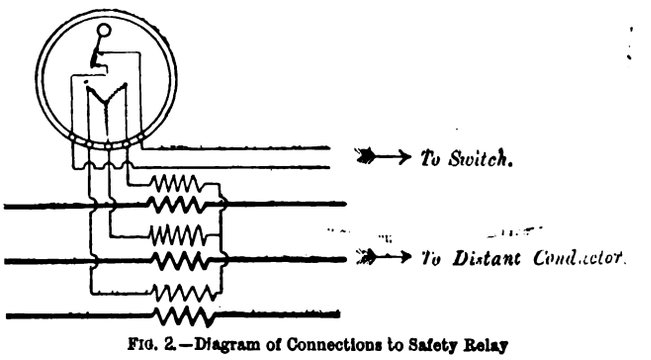

Fig. 2.—Diagram of Connections to Safety Relay

Digitized by Google

of the safety device is principally due to the fact that under normal working conditions the three-phase current produces a turning moment on the drum of a definite value, which is slightly greater than the sum of the separate turning moments which are produced by the short-circuited windings, but which have a value of opposite sign. Consequently the drum with the contact lever moves in accordance with the direction of the three-phase field until contact is made, and remains in this position. When a break occurs in a conductor, the turning moment of the three-phase field disappears, whilst that which is produced by the short-circuited winding immediately comes into operation; consequently the drum with the contact arm turns backwards and closes an exciting circuit connected to an automatic cut-out device of the high-tension switch in the main circuits, which are in this manner disconnected. As little as 3 per cent. of the normal current will serve to operate this relay.

"Duplex" Tumbler Switch.

From Mr. A. P. Lundberg, Pioneer Electrical Works, London, N., we have a sample and particulars of his "Duplex"

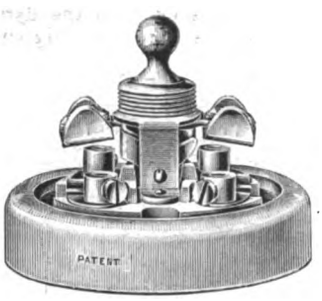

FIG. 1.—"Duplex" Tumbler Switch—Both Contacts "off."

tumbler switch, the most ingenious device of its kind we have seen for a long time. This switch is of the two-way type, with "off" position, all the positions of the knob being exceedingly well defined. A single spiral spring is used, which ensures equal tension on both contact arms. The action of the switch may be explained with the aid of the accompanying illustrations. Fig. 1 shows both contact arms in their "off" positions, while Fig. 2 shows contact arm A "on" and B "off." Referring to Fig. 2, it will be seen that when pin, I, of knob, H, is resting on its step on contact arm A, the horn of contact arm B locks B in its "off" position, as it is unable to pass by I until the

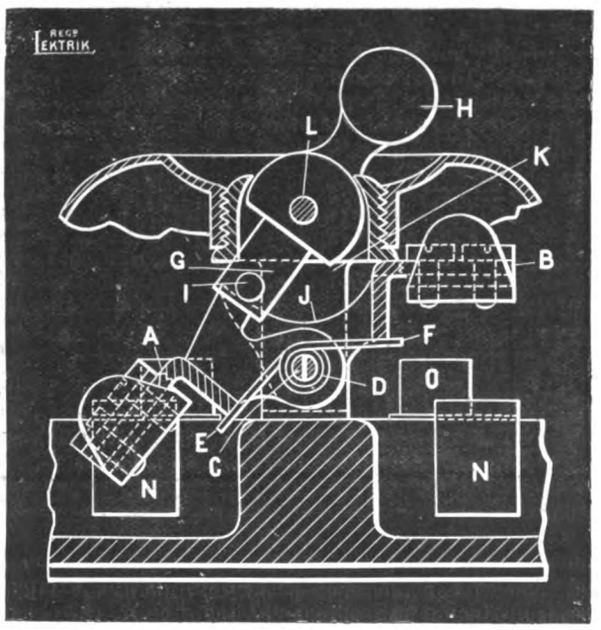

FIG. 2.—Diagram showing Action of "Duplex" Tumbler Switch.

knob, H, is moved; thus A is locked "on" and B "off." As the two contact arms, A and B, are identical in shape, a similar action results when B is "on" and A "off." F is the double-action spiral spring. Whether regarded from a mechanical or an electrical point of view, the design and construction of this switch seem equally satisfactory. Some of its many useful applications are illustrated in a descriptive pamphlet just issued by Mr. Lundberg. These include tramcar lighting, controlling a two-filament lamp, intermediate wiring, controlling arc lamps, etc.

Eversheds Leakage Indicator.

From Messrs. Evershed and Vignoles, Limited, Acton-lane Works, Chiswick, W., we have particulars of a leakage indicator for direct-current two-wire wholly-insulated circuits, which has been devised by them to fulfil as nearly as possible the requirements of the Home Office Rules for the use of Electricity in Mines, Section I., Clauses 6 and 7. The system, which is pronounced satisfactory by the Home Office, provides (1) a continuous indication of any inequality in the insulation of the mains; (2) means of determining in an instant the absolute value of the insulation of each main; (3) means of obtaining the value of the leakage current by a simple calculation. When the instrument in question is connected as shown in Figs. 1 and 2 herewith, the pointer will then rest in the middle of the scale if the insulation of the two mains be sensibly equal (see Fig. 2). But should an earth develop on either, the pointer at once deflects, and shows by the direction of its deflection on which main the failure has occurred. This indication may be supplemented by a bell if required to call the attention of the switchboard attendant. In order to find the absolute value of the insulation of each main, first the + and then the − key must be depressed, and the positive and negative deflections in degrees noted. From these two readings the value of the insulations may be seen instantly by the use of the table supplied with the instrument. Thus, if the + reading be 4

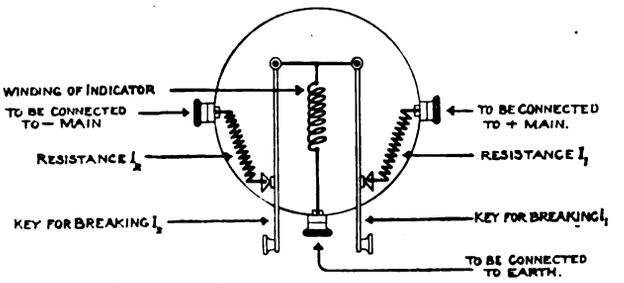

FIG. 1.—Evershed's Direct-Current Leakage Indicator—Internal Arrangement,

and the − reading 10, the insulation of the + main is 150 and of the − main 60 thousand ohms. The leakage current in milliamperes is calculated by dividing the voltage of the circuit by the sum of the figures obtained by the test (in thousand ohms). Thus:

$$\text{Leakage current in milliamperes} = \frac{\text{Volts}}{\text{Sum of insulations (in thousand ohms)}},$$

and, therefore, in the above case with a 500-volt circuit:

$$\text{Leakage current in milliamperes} = \frac{500}{150+60} = \frac{500}{210} = 2\,4.$$

Since the rule lays down that the leakage current shall not exceed one thousandth of the maximum supply current, it follows that the number of milliamperes of leak must not exceed the number of amperes of the maximum supply. Thus, if the full-load current be 500 amperes, the leakage current must not exceed 500 milliamperes. Any leakage beyond the

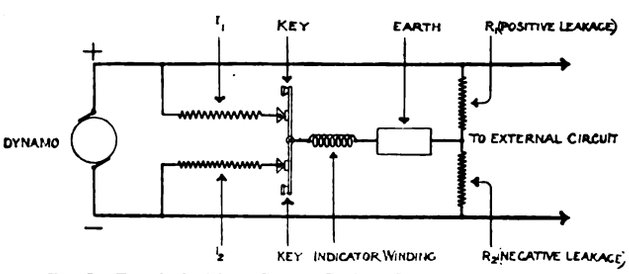

FIG. 2.—Evershed's Direct-Current Leakage Indicator connected as Continuous Alarm.

limits allowed must be located and remedied. Messrs. Evershed and Vignoles recommend the use of their now well-known "Megger" for this purpose. The introduction of leakage indicators is yet one more proof that necessity is the mother of invention, and it reflects great credit on instrument makers that they have been found so ready to meet requirements.

Veritys' Ventilating Department.

Messrs. Veritys Limited announce that they are opening a ventilating department at each of their various branches. This department will deal in "Aston" ventilating fans and blowers, and its services will always be available to the electrical trade where advice is required as to the best means of ventilating buildings and applying forced and induced draught. The department is under the superintendence of Mr. Oswald Stott, who has made a study of this work, and who has had great experience in the manufacture and application of blowers and fans.

Catalogues, etc., Received.

PATERSON PLANT.—A special leaflet which is being sent out by the Paterson Engineering Company, Limited, Amberley

Digitized by Google

House, Norfolk-street, Strand, W.C., illustrates their gravity and pressure filters, softeners, heaters, and grease eliminators. Paterson plant has not been very long on the market, but the list of users is already a lengthy one, and may be taken as a measure of its recognised merit.

ACCUMULATORS. — Portable Accumulators Limited, King Edward's-mansions, 210, Shaftesbury-avenue, W.C., have sent us a copy of their price-list of single cells and complete batteries in glass, ebonite, or celluloid boxes, fitted with low discharge plates of the pasted type.

SIMPLEX CONDUIT.—From the Simplex Steel Conduit Company, Limited, Westinghouse building, Norfolk-street, Strand, W.C., we have a copy of a new price-sheet, which gives in a condensed form most of the prices contained in their 1905 catalogue. This list has been compiled to meet the wishes of the firm's customers for a compact and legible sheet which can be hung up in the office or folded for the pocket.

COLWYN BAY ELECTRICITY ACCOUNTS.

The accounts of the Colwyn Bay and Colwyn electricity department for the year ended March 31, 1905, show a total expenditure on capital account to that date of £21,032. Abstracts of the revenue account, etc., are given herewith.

APPOINTMENTS VACANT.

Electrical Fitter and Repairer, West Africa. Salary, £20 per month. See advertisement.

Estimating Clerk for electric cable manufacturing company. Applications to Cable, *Electrical Engineer* Office.

Charge Engineer, Willesden Urban District Council. Salary, 35s. per week. Applications by Oct. 4. See advertisement.

Winders for direct-current and alternating-current work. Apply to Bruce Peebles and Co., East Pilton, Edinburgh. See advertisement.

Engineering Instructor, the Technical Education Board of Wellington, New Zealand. Salary, £300 and £40 passage allowance. See advertisement in last issue.

Assistant Engineer to act as station superintendent at one of the Edinburgh Corporation's electric generating stations. Commencing salary £180 per annum, rising to a maximum of £270 per annum. Applications by Oct. 2. See advertisement.

ELECTRICITY v. GAS FOR STREET-LIGHTING.

The Croydon Fight.

We have referred several times to the attempts being made at Croydon to discredit the electric lighting of the streets, and in view of the most recent move by the gas companies think it well to reproduce in full the report of the Lighting and Electricity Committee on the matter. The report is dated July 13, and reads:

In accordance with the resolution of the Council passed at the meeting held on May 15, 1905, the committee submit the following report:

THE QUESTION OF REVERSION TO GAS IN OTHER TOWNS.

1. A large number of inquiries have been sent out by the committee, and the inquiries and answers have been tabulated.

2. With the exception of one district in London, where high-pressure gas is being used, no town appears to be reverting to gas, and in this case gas has not superseded electric lighting by arc lamps. On the other hand, the committee find that lighting by electricity is considerably on the increase, and several towns have now no gas lighting in the streets. In reference to Paris the committee find that electric lighting is not making satisfactory progress. It has been found that the prices charged are very high, and as the concession for electric lighting expires in two or three years, when the electricity company have to hand over their entire property to the Municipality without payment, it can hardly be expected that much progress will be made until a new order of things is established.

3. With reference to the city of London, the committee have made careful inquiry on the reported reversion to gas by the City, and find that the City Council have decided to light the following streets by gas—viz.:

4. Queen Victoria-street, part of Queen-street, and Fleet-street. The chairman of the committee stated (*Electrical Engineer*, May 12) that these three schemes were in the nature of an experiment, and nothing further would be done until they were thoroughly tested.

5. The committee cannot discover that there has been any attempt to compare the proposed gas lighting with the more modern systems of electric lighting. The comparison was made (*Electrical Engineer*, May 12) between the suggested gas lighting and the existing arc lamps. The committee consider this a most unreasonable basis on which to make a comparison. It is well known that the existing arc lamps were some of the earliest erected in the country, and the lanterns about as unsuitable as could have been chosen. There are now two electric supply companies competing in the city of London, and the relations between the original company and the Corporation have not been altogether of a harmonious nature. The committee, as a result of enquiries, believe that they are correct in stating that neither electric supply company were asked to submit a formal tender for comparison as to the cost of street-lighting, and under the circumstances, and apart from the fac that the present installation is an experimental one, they do not consider that any importance whatever can be attached to the action of the City Corporation. Taking the estimated cost of the alteration at £2,042. 5s., and the saving anticipated at £323. 11s., it will take 6½ years to repay the initial cost. The committee suggest that the price of £26 per arc lamp would have been considerably reduced on a new tender, and the amount of light increased several fold.

Summary of Particulars relating to Street Lighting in 1894.

Type of lamp.	No. of lamps.	Miles of streets lighted.	Distance apart (yards).	Total cost.	Average C.P. per mile.	Cost per C.P. per annum.	Average C.P.
Gas— Batswing 5 c.f.	1,933	130	118	£ s. d. 6,554 14 5	223	54·25d.	15

6. There can be very little doubt that the above-mentioned average distance between lamps is too high, as it includes certain roads not constructed as well as any roads not lighted. Price of gas: Croydon Gas Company, 2s. 9d.; Crystal Palace Company, 2s. 8d.

7. Between November, 1899, and May, 1902, the Council ordered the conversion of the batswing burners to incandescent at a cost of 4s. 6d. each, the total cost of the 1,997 lamps then existing amounting to £428. 10s. The streets were, however, lighted with lamps of about three times the former candle-power. Price of gas: Croydon Gas Company, 2s. 8d.; Crystal Palace Company, 2s. 5d. The latter company are now increasing their price to 2s. 6d.

8. In the fourth column of the table below "distance apart" the figures are misleading. All the electric lamps have been added during the last few years, in which time the distance

South Suburban Gas Co.*	505	44	2 18 4	·00422	15·82	15·82
8. Electrical Co.'s A.C. Flame arc, 550-watt. Opalescent globe, Brighton-road	1	1 400	18 0 0	00082	3·075	3·075
9. Katharine-street, Santoni lamp, 430-watt	1	1,175	18 0 0	·000978	3·688	3·688
10. Reason incandescent lamp	—	57	3 8 6	·00384	12·403	14·403 (*a*)
			2 18 4	·00326	12·228	12·228 (*b*)

* The lamps in South Suburban Company's area were all newly cleaned and with fresh mantles put on. The tests are therefore much better than if they had been taken after a few days' use of the mantles. (*a*) Croydon area. (*b*) Crystal Palace area.

apart of the lamps has been reduced. The average distance apart given in the table for gas lamps is arrived at by taking the number of miles of streets in the borough after deducting streets lit by electric lamps and dividing the number of gas lamps. This includes several roads not yet lit or only partly lit, and also many outlying roads in which the distance between lamps is excessive.

Summary of Particulars relating to Street Lighting in 1904.

Type of lamp.	No. of lamps.	Miles of streets lighted.	Distance apart (yds.).	Total cost.	Average C.P. per mile.	Cost per C.P. per annum	Average C.P.
				£		d.	
Incandescent gas	2,137	127·375	80	7,062	839	15·862	50
Nernst and incandescent	90	3·67	66	288	1,373	13·71	56
Electric	428	14·5	65	7,212	10,537	11·328	357

9. Again, the above summary is not a correct comparison, as by placing the arc lamps at cross roads 150 gas lamps are saved, or a sum of £513 per annum, which should be subtracted from the cost of arc lighting.

COMPARATIVE COSTS OF PRESENT SYSTEMS.

10. The committee have, for the purpose of comparison, taken (1) the results of tests made by the city engineer of Westminster as being an independent expert; (2) results of tests carried out to their own instructions.

11. Tables at end of report give (A) Westminster results,* (B) Croydon results.

12. The results of the committee's investigations show that very exaggerated claims appear to be made by various interested parties as to the particular type of lamp which they favour, and they feel, therefore, that considerable discretion is necessary in forming an opinion as to the relative costs of the various systems of lighting.

13. The correct basis on which to compare the relative costs of different types of lamps is *the average total cost per candle-power per annum.*

Westminster Tests.

14. The table (A) and the remarks at the bottom of same explain fully the relative cost values of the different systems of lighting.

15. The committee would call attention to the remarks made by the Westminster engineer with reference to the great variations in candle-power due to the condition of the mantles, and that what to the eye appeared to be a slight diminution in intensity results actually in an enormous loss of candle-power. This is a point which requires careful consideration when dealing with the question of gas lighting by mantles.

Croydon Tests.

16. With regard to the Croydon tests, every effort has been made to procure an accurate result, and the committee believe that the same as set out in the table can be taken as such on the working conditions, and there is no doubt that the results for comparative purposes are quite reliable. The electric Nernst lamp for side-street lighting in the South Suburban Company's area are charged at the same rate as the gas lamps in that area, and in the area of the Croydon Gas Company at the rate charged by that company. With reference to the former company's area, these prices will be increased owing to the fact that notice of an increase in the price of gas has been given by them.

17. The present lighting is mainly divisible into four sections: (1) direct-current electric arcs; (2) alternating-current electric arcs; (3) Nernst lighting; (4) incandescent gas lighting.

18. With reference to (1)—direct-current electric arcs—it will be noticed that this works out at an average total cost per candle-power of 8·7d., which is only half the cost of similar lighting by means of Nernst lamps or incandescent gas.

19. It will be seen that the present system of electric lighting by means of direct-current arc lamps in the centre of the town is far more economical than by means of gas lighting. The committee feel, therefore, that the lighting by means of these lamps as carried out in the centre of the town has proved a satisfactory method to the Corporation.

20. (2) It will be noticed in the table of tests that there are three kinds of alternating-current arc lamps at present in use (Nos. 2, 3, and 4).

21. With reference to 650-watt lamps (being No. 2 in the table) it will be noticed that these lamps are almost as satisfactory as the direct-current lamps, and the tests came out much cheaper than the gas or Nernst lighting.

22. (3) With reference to the 450-watt lamps (No. 3 in the table), these work out at approximately the same cost as the Nernst lighting, and are slightly cheaper than gas.

23. With reference to the above alternating-current lamps, although in the case of No. 2 (650-watt lamps) they are satisfactory on the question of cost, and (3) (450-watt lamps) came out cheaper than gas, still, from a lighting point of view, they are not relatively as satisfactory as the direct-current arcs, owing to their not being so efficient—*i.e.*, they will not give the same candle-power for the same amount of energy used—and, further, the colour of the light is not so satisfactory.

24. Street-lighting by means of alternating arcs has not been so satisfactory as by means of direct-current arcs, but this difficulty has now been got over by means of the introduction of a new type of lamp, from which the amount of light obtained from a given amount of electrical energy is enormously increased.

25. There is a further objection which must be borne in mind in considering any suggestion of using incandescent gas lamps in the main thoroughfares, even supposing the cost would warrant it, and that is with the present number of tramway poles in the streets the addition of a large number of extra poles in these streets would be a serious matter.

26. The committee are of opinion that the Corporation will not be disposed to reduce the amount of illumination, more especially in the main roads, but, on the other hand, would prefer that the amount should be increased.

27. The committee feel that in aiming at the best lighting of the streets, it is far better that the lamps should be suspended fairly high up so that the light will be properly diffused, and that it should be out of the line of vision of pedestrians and

* We have not reproduced the Westminster figures, as they have from time to time been given in our columns.

Digitized by Google

persons in charge of vehicular traffic, the reason being that a light which is not high up will obscure the view of persons, and with the large volume of traffic in the streets, which in this borough is increasing very rapidly, the likelihood of accidents would be considerably increased. This statement can be easily proved by anyone who watches the traffic passing along the streets lighted by high candle-power lamps suspended at a height of, say, 25ft. and along one lighted by lamps where they are of the ordinary height. There is the further advantage of the light rays from the higher placed lamp being in a more vertical direction.

28. With reference to arc lamps, provided they are maintained in reasonable condition, the amount of light will not vary from day to day. In the case of both Nernst and the incandescent gas lighting, there is considerable falling off in candle-power from the time these lamps are first brought into use.

Side-Street Lighting.

29. It will be noticed that the Nernst lighting comes out slightly more advantageous than gas lighting, and, therefore, there is every justification for the Council lighting the side streets by means of their own supply in those streets where the mains are laid.

30. It will be seen from the table that, although the charges made by the South Suburban Gas Company are less than those of the Croydon Company, still the light obtained is not so good, and therefore there is not much actual difference.

Possible Improvement in the Present Street-Lighting.

31. The committee have gone into the question of what improved forms of lighting there are now on the market. The improvement in gas lighting for outdoor open spaces has been by the adoption of high-pressure lamps. These lamps, of course, take a very much larger amount of gas than the ordinary lamp. The number of mantles used is also considerably more if a reasonable efficiency is to be obtained. The cost of the mantles is more and the amount of attention is greater. All these points necessitate a much higher price being charged for such a lamp. There is a further serious disadvantage in connection with the use of these lamps, it being necessary to have a gas-engine or other form of pumping machinery to do the necessary pumping for the same. This also requires attention, and in addition there is the cost of upkeep of the plant.

32. Several kinds of this type of lamp are at the present time being tried in London. The committee would emphasise the point previously mentioned that the gas lamps were fixed rather low, and although the amount of light thereby obtained appears to be greater, the committee consider that it is advisable lamps of larger candle-power should not be fixed low. To get a satisfactory arrangement for street-lighting, the lamps should be of a height that they give a good diffused light, and are well above the line of vision.

33. Making due allowance for the above facts, the committee find that gas lighting has considerably improved by means of high-pressure lamps, but although these advances have been made, so long as the price of the electric arc lamps does not exceed a certain amount, the cost of lighting by means of the ordinary direct-current arc lamps should be more economical than by the high-pressure gas lamps.

34. The committee also find that considerable improvements have been made with electric arc lighting. This has been primarily brought about by the introduction of a new type of arc lamp known as the "flame arc lamp." They have had some of these erected for their inspection, and tests made on the same, the results obtained being very satisfactory. On the table showing the results of the Croydon tests No. 8, reference is made to one of these lamps fixed on the alternating supply. If the candle-power of this new type of lamp is compared with that obtained from the direct-current lamp, which is the most efficient at present in use, it will be seen that in the case of the former approximately treble the light is obtained for the same cost of electrical energy.

35. If one of the gas lamps being installed in the city and described by their makers as 600 c.p. is compared with the sample of the new flame lamp which has been hung in the Brighton-road for the committee's inspection, the candle-power of which on test is actually 1,400, it will be found that with the light from the arc lamp at two and one-third times as much as the light from the gas lamp and the price of the electric arc lamp approximately half as much again as the gas lamp, the price of the former works out at less than half the price of the latter on the basis of light value. The price proposed to be charged for the gas lamp installed in the City is, we understand, £12. 10s., and the price charged per arc lamp in Croydon is £18.

36. The committee would also like to point out for the further information of the Council that the rays given off by this type of lamp are very satisfactory in the penetration of fogs, they being of a reddy yellow tendency. On the other hand, the high-pressure gas lamp's rays are somewhat similar to those of the electric arc lamps, which are not so satisfactory for lighting purposes during a fog.

37. The question of whether more efficient lamps cannot be erected to replace those at present in use, so that the borough should have the most efficient and up-to-date lighting at present known, is a matter which can be dealt with separately, as it does not affect the present question.

38. At the meeting of the Council held on April 17 the following resolution was carried: "That having regard to the heavy expenditure involved in the present mode of lighting the borough, the Lighting and Electricity Committee be requested to carefully consider the matter and make such suggestions to the Council as may tend to considerable reduction in the cost of street-lighting."

39. The committee are of opinion that the result of their investigations had been to show that, taking all things into consideration, the system of lighting which has been adopted is most satisfactory, and they wish further to point out that even if the balance in its favour has been very small indeed, it would yet be in the interests of the Corporation to keep the lighting of the borough as far as possible in its own hands, and so retain any advantage which may accrue through a larger output of the Corporation electricity works. This should carry due weight with any decision that may be arrived at in connection with the matter, as an advantage to any Corporation department means, of necessity, an advantage to the whole of the ratepayers.

40. The examination of each year's working shows that the average cost of supplying electric light has been gradually reduced, and, therefore, the committee feel that the Council should assist them as far as they are reasonably able to do to increase the output of the works, as by so doing it would be conducive to lower cost of production.

41. The amount spent on street-lighting by the electricity department amounts to £13,552, and the annual charge on the amount for interest and sinking fund amounts to £813.

42. The committee have, from time to time, given reductions to all classes of consumers, and they now recommend that arc lighting be reduced by £1 per lamp per annum as from Sept. 29.

July 13, 1905. D. B. Miller, Chairman.

To this report the two gas companies have replied under the date of 15th inst. by a letter which we abstract as follows:

Gentlemen, — The directors of the Croydon and South Suburban Gas Companies have had their attention drawn to a report on street-lighting, dated July 13 last, by your Electrical Committee.

We are instructed to appeal to your sense of justice to allow us to put the case from another point of view, believing that your desire must be to have the streets lighted in the best manner at the lowest cost. We desire to prove by this reply to your committee's report, and by practical experiments to be carried out with your permission in suitable positions in the borough, by each company at its own cost, that incandescent gas lighting is the most efficient and much the cheapest street illuminant. Our directors desire to point out that, to obtain a fair view of the matter, the Council should treat the report as a statement of an electrical department anxious to maintain and extend its business, and should accordingly reserve judgment till the following facts have been considered. It may also be remarked, with reference to the note after Table II. at the end of the report, that it is the practice of the companies to maintain the mantles in good order from day to day—fresh ones being fixed as required. The conditions in which they were seen was, therefore, their normal state.

The report states that "lighting by electricity is considerably on the increase, and several towns have now no gas lighting in the streets." As the towns are not named, nor the particulars given, that statement can only be dealt with generally; but it may be assumed that these are places where the electricity supply is owned by the respective towns and the gas supply is by companies. It by no means follows that to light the streets in the most efficient manner, and at the lowest cost, has been the paramount consideration in these cases. It is most probable that electric lighting has been adopted or extended, on considerations such as those set forth in your committee's report, in order to obtain an increase of business for the electrical department.

If in the towns referred to electricity and gas were both supplied by companies, and the former had been adopted in fair competition, the statement of your committee would have been difficult to answer; but it so happens that in both the important cases mentioned—viz., Paris and London—where both lights are supplied by companies, electric street-lighting, as admitted in the report, is losing ground. Your committee tried to explain that "electric lighting is not making satisfactory progress" in Paris by stating that "the prices charged are very high" (no doubt because the price of electricity is high enough to pay expenses); but they omit to state the fact that the price of gas in Paris is also much higher than in Croydon.

The letter then deals with the city of London experi-

Digitized by Google

ments, which have been explained in detail in our columns, and hence deleted, and then goes on as follows:

To return to the report, certain tables are given in which are set out various particulars of the number, distance, candle-power, and the cost of flat-flame and incandescent gas lamps and arc and Nernst incandescent electric lamps. As to the Nernst electric lights, the report says these "are charged at the same rate as the gas lamps." But it does not say that this is a paying rate, there being little doubt that there is a considerable loss. Moreover, these lamps are only 72 yards apart, against 105 yards for the gas lamps. Then it is said "that the Nernst lighting comes out slightly more advantageous than gas," and the Council are advised to light "the side streets by means of their own supply" in this way, which is certainly less efficient and more costly than gas if a paying price is charged.

The first table gives the position in 1894, when batswing flat-flame burners of about 15 c.p. were exclusively used, and the lamps averaged the extreme distance of 118 yards apart, the cost averaging £50. 8s. per mile.

There appears to be a serious and misleading error in the table relating to 1904, which greatly understates the distance apart of the gas, slightly understates that of the Nernst lamps, and overstates that of the electric, as follows:

	Average distances apart.	
	As per table.	Corrected.
Gas lamps	80 yards	105 yards
Nernst lamps	66 ,,	72 ,,
Electric	65 ,,	60 ,,

The gas lamps are 76 per cent. farther apart than the electric arc lamps—that is, there are seven electric against four gas in an equal length of street. Probably one reason for this is to be found in the necessity of placing the arc lamps in so lofty a position, and in the fact that at greater distances the lights would cause very unpleasant alternations of light and shadow. It is a strong testimony in favour of gas that, with lamps so far apart as 105 yards on the average, the borough is as well lighted as it is at present.

In both tables there is a serious omission; in fact, the information given in the seven columns is scarcely intelligible, and is of very little value without the addition of a column giving the cost of lighting per mile of street. This, according to the figures of the second table, average as follows:

Incandescent gas in 1904	£55 8s.	per mile
Nernst electric	78 10	,,
Electric arc	497 5	,,

Moreover, these figures are unfair to gas, inasmuch as they are calculated on the assumption that the hours of lighting are the same for gas as for electricity; the fact being, however, that while each gas lamp is alight throughout the hours of darkness—that is, some 3,980 hours out of the 8,760 in each year—the electric lamps are extinguished at varying hours, many of them at 11 o'clock or midnight.

The cost of lighting has been more than doubled over the entire borough by the adoption of the electric light in about 18 miles of streets out of a total of 145 miles—that is, gas costs less by £438 for 127 miles than electricity for 18 miles.

127 miles of gas cost in 1904			£7,062
3½ ,,	Nernst electric	£288	
14½ ,,	arc electric	7,212	
			7,500
Difference			£538

The cost of electric lighting is given as £7,500 for the year 1904; but in one paragraph the capital cost of the installation is given as £13,582, and it is stated that "the annual charge for interest and sinking fund amounts to £813," which is not included in the £7,500. That figure should, therefore, be increased to £8,313. This makes the cost of lighting 18 miles of streets electrically exceed by £1,251 per annum the cost of lighting 127 miles by gas.

The report says: "The correct basis on which to compare the relative cost of different types of lamps is *the average total cost per candle-power per annum.*" The committee cannot be aware of the difficulty and uncertainty of making photometric tests in the streets, and of the small practical value they have when made, or they would not have penned that sentence. Mr. Morton, the chairman of the City Streets Committee, gave a much better and a really intelligible basis in his speech at the meeting on May 4 of the London Corporation. He said, "In his opinion the best test of good lighting was a man's own test—that was to say, for a person to himself ascertain which illuminant was best to see by." This was practically endorsed by Mr. Williams and by Mr. Cooper in following speeches.

According to Table II. the average candle-power is given, for what it is worth, at 839 candles per mile of street for gas, and 10,537 for electric arcs. Either the one is woefully deficient or the other is scandalously extravagant. What is the use of a comparison of costs based on candle-power per annum when, according to the figures given, to effectively light the streets by one kind of lamp 10,000 candles must be provided per mile, against 800 with the other. Things that differ to such an extent cannot be compared by saying that the extravagant one costs only 11·328d. while the enormously cheaper one costs 15·862d. per candle-power per annum. Note the exactitude of these figures—to three places of decimals of a penny. In fact, the cheaper article in this case is much the dearer, for no man in his senses would think of buying 10,000 articles at 11d. each when 800 of another kind at 15d. would answer his purpose.

"The proof of the pudding is in the eating," and the proof of the lighting is in the seeing. Will the Corporation set apart a certain representative length of street or streets in the districts of the respective companies, and allow them to light them with incandescent gas, high pressure or otherwise, or both, as the Corporation may decide, with or without a limit of price per mile of street, and in a manner which, if adopted by the Council, would represent to the ratepayers an annual saving equal to at least a rate of 1d. in the £, and which it is contended would compare favourably with present electric arc lighting. If so, the companies will be glad at their own expense to supply and fix columns, lanterns, and burners, to effectively light the places selected, and remove the same after a trial of not less than six months, if not approved; but if the Corporation wish the lighting continued, they shall pay to the companies the cost price of the installation—these being the conditions offered to the City Corporation in connection with Southwark Bridge.

In the report it is stated that, "in aiming at the best lighting of the streets, it is far better that the lamps should be suspended fairly high up, so that the light will be properly diffused, and that it should be out of the line of vision of pedestrians." This presumably refers exclusively to electric arc lighting, as only these lights are "suspended." The principle enunciated is contrary to all experience and practice in gas lighting. Gas lights of moderate illuminating power, 10ft. or 12ft. from the ground and fairly near together, give a result in uniform illumination which is most necessary for the efficient lighting of the streets, and which is utterly unattainable by electric arc lamps.

The report recommends an extension of the arc lighting in order to increase the output of the electricity works, though nothing definite is said about the profit of so doing. But making the improbable supposition that some small profit may be made, it cannot be right to call upon the ratepayers to pay another £7,000 a year for electric lighting, less the fraction saved by abolishing gas, in order to increase the output of the electricity works at little or no profit, or possibly at a loss.

If the Corporation contemplate spending £500 a mile per annum for public lighting by electricity when it can be more efficiently done with gas at less than half the cost, the gas companies make the request that the decision be delayed until after the proposed experiment has been made.

(Signed) CHARLES M. OHREN,
Secretary, South Suburban Gas Company.
WILLIAM W. TOPLEY,
Secretary, Croydon Gas Company.

Sept. 15, 1905.

PERSONAL.

The Swindon Town Council have increased the salary of Mr. J. G. Griffin, the electrical engineer, from £300 to £325 per annum.

The Mansfield Town Council have increased the salary of the assistant engineer, Mr. B. Sankey, from £140 to £155 per annum.

Mr. W. A. Toppin has been appointed superintendent of the meter and installation department of the Greenock Corporation at a salary of £130 per annum.

Mr. J. R. Salter is engaged as consulting engineer to the Heywood Town Council in the supervision and completion of the Hopwood section of the tramways.

The Epsom Urban District Council have voted their electrical engineer, Mr. H. F. Foster, £10. 10s. for extra services rendered by him in connection with the waterworks pumping scheme.

Mr. F. Schofield, the traffic manager of the Bradford City tramways, has been presented with an illuminated address, a barometer, and a cheque, on the occasion of his leaving Bradford to take up the managership of the Leyton tramways.

Mr. P. A. Locke, senior chargeman at Plymouth Corporation electricity works, has been appointed chief lecturer in electricity under the education authority of Bolton, Lancs. Mr. Locke has been senior chargeman at Plymouth for five years, and has for some time been lecturer in electricity at the Plymouth technical schools.

The Burnley Corporation Electricity Committee have appointed Mr. James E. Starkie, A.M.I.E.E. (subject to the approval of the Council), to the position of borough electrical engineer in succession to Mr. Birkett, who resigned in May last to take up a similar position at Southend-on-Sea. Mr. Starkie has been engaged at these works about four years, the last three years of which he has been chief assistant engineer.

LEGAL INTELLIGENCE.

COLLISIONS.

At Wood Green County Court James Chilcott, motor engineer, Hendon, brought an action against the Metropolitan Electric Tramways Co. to recover £91. 10s. for personal injuries sustained and damages in connection with a collison.

PLAINTIFF stated that he had been repairing a motorcar, and on April 6 went out to test it. The owner and another gentleman were in the car. Just as they got upon the tramlines in Edgware-road the engine of the car stopped and he got out to start it. An electric car was approaching and a signal was given for it to stop. It did ease up partially, but forged ahead again and smashed into the back of the motorcar, pitching witness against the wheel of one of Messrs. Carter-Paterson's vans. He was injured so badly that he was confined to his bed for a fortnight; he could not resume work for a month, and he still felt the effects of the accident.

Mr. MANSFIELD, clerk and surveyor to the Kingsbury District Council, stated that he saw the signal given to the tram driver to stop.

Several witnesses for the defence stated that the motor ran about the length of a tram in front of the electric car and stopped. The collision was an accident and unavoidable.

HIS HONOUR considered the accident was brought about by the driver of the tramcar proceeding at a greater rate than he ought to have done and not checking his speed before the collision occurred. The verdict would be for plaintiff, with 40 guineas damages and costs.

At Wood Green Police Court Wm. Charles Wingate, an electric tramcar driver, was summoned at the instance of the police for wantonly driving a car.

P.C. 297 Y stated that he saw defendant driving his car along the Green-lanes near Turnpike-lane, Hornsey. He collided with a cart laden with clay, which had the effect of knocking the horse down and throwing the vehicle upon the footway. The cart in turn collided with a coster's barrow just in front, the occupant of which was thrown out and slightly injured. Defendant did not ring his bell and did not pull up.

THOMAS KEEN stated that he witnessed the affair. The car was travelling 10 miles an hour and the cart was "making its way off the tramlines" when they collided. What surprised him was that the defendant did not pull up.

WM. KITCHENER, driver of the cart, stated that without any warning whatever the tram struck his cart. No bell was rung.

JOHN EDEN, of Park Ridings, Hornsey, owner of the barrow, corroborated.

Mr. HUGHES submitted that the affair was a pure accident. The summons was for "wantonly driving"; that meant wilfully, if anything at all. Therefore, it must be proved that the driver was not guilty of a lack of judgment, but that it was a wilful and wanton act.

DEFENDANT (sworn) stated that he rang the bell four times. Just as he was passing the driver of the cart pulled out to pass the barrow.

JAMES WILLIAMS, of 60, Lordship-lane, Wood Green, said he was in the engineer's department of the Middlesex County Council. He was in the car on the day in question, and he heard the gong sound two or three times. As the tram was passing by the cart turned out; a collision was unavoidable. It was a pure accident. The constable went to the driver three times and told him he was to blame. Witness interfered and told the officer that he was not justified in saying what he did in the presence of persons who might be called as witnesses.

The Magistrates held that "wanton driving" had not been proved, and, therefore, dismissed the case.

ALLEGED LONG-FIRM FRAUDS.

At the Guildhall on Tuesday, before Mr. Alderman Burnett, William Leslie, 40, described as an electrical engineer, and Alice Frances Cheesman, 24, a typist, were charged with conspiring, with others in custody, during the months of May, June, and July, to defraud Messrs. Strode and Co., of St. Paul's-churchyard, and other firms. Particulars of the case have already appeared.

After hearing further evidence Mr. Alderman Burnett remanded the prisoners until to-day.

COMPANIES' MEETINGS AND REPORTS

DICK, KERR, AND CO.

The report for the year ended June 30 last, to be submitted to the meeting on the 28th inst., states that the profits earned during the 12 months amounted to £85,007. Out of this had to be paid debenture and loan interest and trustees' fees, and there has been reserved the sum required to provide for the premium payable on the redemption of the present debenture stock. These items absorb £14,853, leaving a balance of £70,154, to which must be added the profits brought forward from last year—namely, £39,922—making a total of £110,076 available for appropriation. It is proposed to carry to a special reserve for extensions of manufactories or replacements of machinery, etc., or special depreciation of same (referred to below) £23,389, to pay a dividend of 10 per cent. on the ordinary shares, and to carry forward £42,388. During the past year the Company has been fully employed on important contracts both at home and abroad, and the manufacturing departments have been kept busy. The prospects for the current year are encouraging, although the directors think it right to draw the attention of the shareholders to the severe competition which exists in all branches of the business. The directors called attention last year to the fact that the reserve to be set aside, under Clause 31 of the trust deed, had then reached the limit of £150 000 prescribed by that deed, and they now desire to draw the attention of the shareholders to a new reserve which has been begun. In the previous balance-sheet there was shown a special reserve of £32,611, and the directors propose to transfer £16,611 from this reserve and add to it the sum of £23,389, so as to bring the total amount up to £40,000, this reserve to be set aside for the specific purpose of extensions of manufactories or replacements of machinery, etc., or special depreciation of the same.

MEXICO ELECTRIC TRAMWAYS.

The report of the directors of the Mexico Electric Tramways for the year ended Dec. 31, 1904, states that the result of operations, after charging interest on the debentures of the Compañia de Ferrocarriles del Distrito Federal de Mexico, and after payment of the 3½ per cent. guaranteed on the share capital of that company (under the terms of the lease), shows a net profit of the sum of 453 675dol., which, at the rate of exchange of 22¾d., gives the sum of £43,004 to be carried forward to the credit of the London profit and loss account. The interest received on the debentures of the Compañia de Ferrocarriles del Distrito Federal de Mexico (4,000,000dol. of which is held by this Company) and the dividend declared by the Compañia de Ferrocarriles del Distrito Federal de Mexico on its share capital (all of which is held by this Company) is then added, and, after charging expenses and obligations, etc., against the same, a net balance is shown to the credit of profit and loss account of the sum of £53,896, which, added to the balance brought forward from last year of £5,728, gives the total sum of £59,625. Out of this sum the usual dividend of 6 per cent. has been paid on the preference shares, amounting to £30,000, and a depreciation reserve account has been credited with the sum of £15,000, leaving a balance of £14,625 to be carried forward to next year's account. During last year the La Piedad mule line was reconstructed and opened to electric traction on May 30, and also during that year the reconstruction work to electric traction was commenced both on the Tacuba and Atzcapotzalco line, and also on the Peralvillo New Rastro mule line. To meet the requirements of these new lines and the traffic generally, 28 new passenger cars were added to the Company's equipment. In addition to these, four new express cars, 12 express wagons, and 25 freight cars were also added to the service. As already reported to the shareholders, during the year 1904 the purchase of the Mexican Traction Co.'s interests was concluded. This company was the owner of an important town line, called the Baños, and also possessed many other street concessions in the new quarter of the town, all of which now form a valuable addition to the system.

NEW COMPANIES REGISTERED.

British and Continental Traction Syndicate, Limited (35,791). Capital, £500. Object as indicated by the title. Registered office, 53, New Broad-street, E.C.

Lien Registered.

Beberlein Company, Limited (Makers of Engineering and Electrical Supplies, etc., London).—Issue on Sept. 1 of £200 debentures, part of a series created Feb. 29, 1904, to secure £2,500, charged on the company's undertaking and property, present and future, including uncalled capital. No trustees. Total amount previously issued of same series, £1,280.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Florianopolis (Brazil).—The Municipality require tenders for the lighting of the town by Oct. 2.

Spain.—The Arsenal Authorities require tenders for a quantity of copper and lead in sheets and bars. Tenders by Sept. 27.

Martorell (Province of Barcelona, Spain).—The Municipality require tenders for public electric lighting. Tenders by Sept. 23.

Pontypridd.—The Urban District Council invite tenders for (Section B) overhead equipment for tramways; (C) cables for tramways. Tenders by noon on Sept. 30.

Burton-upon-Trent.—The Corporation invite tenders for the supply and laying of feeder cables, conduits, and other works in connection therewith. Tenders by noon on Sept. 25.

Bishop's Stortford.—The Urban District Council invite tendesr for lighting such of the public streets as are at present lighted, for two or three years from Sept. 30. Tenders by 4 p.m. on Sept. 25.

Wemyss (Scotland).—Tenders are invited for the construction of the permanent way of the Wemyss tramways. Tenders to Mr. Stephen Sellon, 36, Victoria-street, Westminster, by 12 noon on Sept. 27.

London, E.C.—Tenders are invited for supply and delivery of electric plant and materials to the East Indian Railway Co. Tenders to Mr. C. W. Young, secretary, Nicholas-lane, London, E.C., by 12 noon on Sept. 27.

Paris.—The Colonial Office, 4 rue Jean Nicot, Paris, require tenders for galvanised iron wire for the Indo-China telegraph service. Tenders by Oct. 10. Specification from Inspection Générale des Travaux publics, room No. 146, at above address.

Manchester.—Tenders are invited for the electrical installation of the new chief fire station and police station, London-road, Fairfield-

Digitized by Google

street, and Whitworth-street, Manchester. Tenders to the Chairman of the Watch Committee, Town Clerk's Office, Town Hall, Manchester, by 10 a.m. on Sept. 27.

Langho (near Blackburn).—The Chorlton and Manchester Joint Asylum Committee invite tenders for the supply and fixing of the necessary telephones and electric bells at the new colony for epileptics at Langho, near Blackburn. Tenders to the Clerk, Chorlton Union Offices, All Saints', Manchester, by Oct. 3.

London, S.W.—The London County Council invite tenders for the manufacture, supply, and delivery of 34 steel single-deck tramcar bodies; maximum traction swing bolster trucks for 34 electric cars; complete electrical equipments for 34 cars; or, alternatively, 34 steel single-deck cars, with trucks and equipments complete. Tenders by 10 a.m. on 29th inst.

London County Council.—The London County Council invites tenders for the manufacture and laying of (*a*) 56 miles low-tension lead-covered, paper-insulated cables, 20 miles dry-core telephone cables, cast-iron feeder pillars, etc.; (*b*) 24 miles extra high-tension three-core, lead-covered, paper-insulated cables, etc. Tenders to Mr. G. L. Gomme clerk, by 10 a.m. on Oct. 3. See advertisement in last issue.

Erdington.—Tenders are required for the construction of Section No. 1 of the Erdington tramways, comprising the laying of the permanent way, including copper bonding, wood block paving, and other works incidental to the laying of about 2½ miles of double-track tramway, for the Tramway Committee. Tenders to the joint engineers, Mr. Robert Green (of Messrs. Pritchard, Green, and Co.), of 37, Waterloo-street, Birmingham, and Mr. Herbert H. Humphries, engineer to the Council, Public Hall, Erdington.

Municipal Board of Mussoorie (India).—The Municipal Board invite tenders for the supply, delivery, and erection at sites, in complete working order, of the following plant: (*a*) steel power pipes; (*b*) water-motors; (*c*) alternators with exciters; (*d*) switchboards with instruments and apparatus; (*e*) transformers; (*f*) induction motors; (*g*) pumps; (*h*) workshop machines. Also for the supply and delivery of the following: (*a*) bare copper wire for overhead mains; (*b*) insulators and lightning arresters; (*c*) arc and incandescent lamps; (*d*) telephone equipment; (*e*) workshop tools; (*f*) general stores. Specifications, form of tender, and general conditions can be obtained on application to Mr. C. H. Shanan, municipal electrical engineer, Municipal Office, Mussoorie, India (telegraphic address, Shanan, Mussoorie), on payment of a deposit of Rs.75 (£5), which amount will be returned on receipt of a bona fide tender. Tenders by Oct. 23.

RESULTS OF TENDERS.

Foreign Contract.—Messrs. Thomas Piggott and Co. have secured an order for 17 of their patent stamped steel tanks for South America.

Croydon.—The Corporation have accepted the tender of T. Harding Churton and Co. for the supply of single-phase induction motors and centrifugal pumps.

Buralem.—The Town Council have decided to order from Dick, Kerr, and Co. a 200-kw. engine and dynamo in place of the set remaining to be delivered by them.

Caerphilly.—The Urban District Council have accepted the tender of Johnson and Phillips, of Old Charlton, London, at £4,247. 16s. 5d., for electric lighting the district.

Hammersmith.—The Borough Council have accepted the tender of the Main Colliery Co. for supply of best through-and-through steam coal up to March, 1906, at 13s. 9d. per ton, delivered at wharf.

Neath.—The Rural District Council have affixed the seal of the Council to a number of documents in connection with the electric lighting undertaking, including contracts with Callender's Cable Construction Co. at £8,449. 17s., and Johnson and Phillips at £9,335. 17s. 9d.

Fulham.—The Guardians have accepted the following tenders for the supply of 5 000 tons of steam coal to the electricity department: Charrington, Sells, Dale, and Co., £1,191. 13s. 4d., 2,000 tons; Orynant Colliery, £716. 13s. 4d., 1,000 tons; Cory Bros. and Co., £704. 3s. 4d., 1,000 tons.

Taunton.—The Town Council have accepted the tender of Babcock and Wilcox, at £1,460, for a new boiler, fitted with superheater and economiser, also high-pressure pipe extensions and sundry ironwork; and that of C. Goodland and Sons for the supply of 2,500 tons Main colliery coal, at 13s. 11½d. per ton, for the electricity works.

Ebbw Vale.—The District Council have accepted the following tenders in connection with the installation of electric street-lighting: W. T. Glover and Co., £3,708, cables; R. Blackwell and Co., £6,159, overhead wires; Electric Glow Lamp Co., £583. 4s. 6d., street lamps; or Nernst lamps, £643. 12s. 6d.; Reason Manufacturing Co. and Messrs. Rumney, meters.

Institution Journal.—The *Journal* of the Institution of Electrical Engineers (part 175), edited by the secretary, Mr. G. C. Lloyd (Messrs. E. and F. N. Spon), contains "The Eddy-Current Brake for Testing Motors," with discussion, by Messrs. D K. Morris and G. A. Lister (Birmingham Local Section); "Alternate-Current Motors in Industrial Service," with discussion, by Mr. P. D. Ionides (Glasgow Local Section); "E.M.F. Wave Forms," by Messrs. E. A. Biedermann and J. B. Sparks (Students' Section); "The Present Electrical Equipment of the London County Council Tramways," by Mr. J. W. Anson (Students' Section); "Application of Electricity to Mines," by Mr. A. C. Anderson (Birmingham Local Section); "Electric Heating: Its History and Development," by Mr. A. E. Jephson (Students' Section); "Equipment of a Generating Station, with special reference to the Chelsea Station of the Underground Electric Railway," by Mr. R. F. Chaffer (Students' Section).

BUSINESS NOTES.

TRACTION.

Nottingham.—An immediate commencement of the Sneinton tramway is promised.

Birmingham.—Good progress is recorded in the reconstruction of the tramways for electric traction.

Leven.—The Town Council have sanctioned the laying of a double line from the starting point to the Royal Bank.

Paisley.—The company has been requested by the Tramways Committee to provide a through service from east to west.

Perth.—All the generating machinery is in readiness, and some trial trips will probably be made on the new cars in a day or two.

Geneva Tramways Co.—The traffic receipts for the month of August were £8,958, being an increase of £106 over the corresponding period of last year.

Leith.—Colonel von Donop last week inspected, on behalf of the Board of Trade, the section from Pilrig to Newhaven, and expressed satisfaction with it.

London United Tramway Co.—A petition having the signatures of 359 residents and ratepayers has been presented against the Richmond-road extension.

Ramsgate.—It is reported that, as the result of the recent accident, expert motormen are being put on the cars to take charge while descending dangerous hills.

Devonport.—Mr. J. W. Endean, who recently resigned his position as manager of the Devonport and District Tramways Co., has been arrested on a charge of embezzlement.

Chatham.—The Town Council have received a letter from the light railway company stating that the extension to Rainham will not be proceeded with until after the winter.

Motor-'Bus Schemes.—It is reported that several new schemes are about to be launched. They provide for linking up coast towns in the South and the East of England and in Wales.

Lowestoft.—The surveyor has been instructed to submit an estimate on the cost of converting St. Peter's-street to double line. The question of laying a double line in the High-street has been deferred.

Anglo-Argentine Tramways Co.—At a Board meeting an interim dividend of 3s. per share, free of income tax, was declared on the ordinary shares of this company on account of the profits for the year 1905.

Greenock.—The Board of Trade, on application by the Corporation, has awarded the sum of £602. 18s. 9d. as share profits due by the tramways company under Article 5 of the Corporation lease for the year ending Dec. 31, 1902.

The Underground.—The process of displacement of the steam trains by the electric locomotives is proceeding apace, and it is stated that the first-mentioned form of traction will entirely disappear from the system within a couple of months.

Thornaby.—The Town Council have decided to press upon the Imperial Tramways Co. the necessity of proceeding with the doubling of the lines between Thornaby and Middlesbrough, as provided for in the recent Act obtained by the company.

Leicester.—The inquest on the body of Mrs. Henton, who was killed by an electric tramcar, resulted in a verdict of accidental death, the coroner remarking that there was no reason to suppose that the driver did not pull up as quickly as possible.

Cardiff.—At the meeting of the Electricity Committee it was reported that the assessment of the tramways had been increased by 200 per cent., representing an additional £2,000 in rates. It was decided to communicate with the town clerk.

Motor 'Buses as Railway Feeders.—At the half-yearly meeting of the Glasgow and South-Western Railway Co. Mr. Patrick Caird (chairman) announced that the directors had placed orders for numerous passenger road motors, which they hoped would act as feeders to the railway.

East Ham.—At the meeting of the Borough Council a resolution was submitted that, instead of the balance of £2,612 on the trams being placed to reserve, a sum equal to a penny rate should be devoted to the general district rate. After some discussion the matter was referred to committee.

Pontypridd.—At the meeting of the Urban District Council a number of tenders were opened for the construction of the permanent way of the tramroad to the junction at Hafod with the proposed Rhondda tramways, and they were referred to Mr. R. P. Wilson, the Council's consulting engineer.

Dundee.—It was inadvertently stated last week that the coal consumption had been brought down to 1·88*l*. per unit. The figure should have been ·188*l*. per unit. The residents along Victoria-road and the neighbourhood have prepared a petition strongly urging an extension of the tramway in their district.

Llandudno Light Railway.—The promoters have obtained an extension of time for constructing their system until Dec. 31 next year. The Board of Trade stipulate that the line shall be open for traffic by that date from Rhos Road to Llandudno, a distance of about four miles. The Board intimate that, failing compliance, the order will be suspended.

Birmingham and Midland Tramways.—The receipts of the Birmingham and Midland and City of Birmingham Tramways show a decrease owing to the omnibus receipts of those companies having hitherto been included. The omnibus business has been sold to the Birmingham and Midland Motor Omnibus Co., which is an associated company of the British Electric Traction Co.

Digitized by Google

Piccadilly, etc., Railway.—On Monday last the directors of the Great Northern, Piccadilly, and Brompton Railway inspected the new cars designed for use on this system. Owing to the restricted space available in the tunnels, the roof is rather low-pitched, but the cars are roomy and comfortable. The body of the car is built of steel, and the interior woodwork has been rendered non inflammable.

Hastings.—The sub-station and car-shed which are in course of erection at Bulverhythe are nearing completion, and as the lines are already laid from the end of the wood paving at West Marina to Bexhill, and in Bexhill itself, the company contemplate commencing a service between Bexhill and Bopeep in a day or two, without waiting for the completion of the front line. The company have applied to the Corporation for sanction to Sunday running, and it is probable that a *plébiscite* will be taken.

Tram Tokens.—At a meeting of the Tramways Committee of the Newcastle Corporation a report was presented from the manager respecting the giving of tram tokens to officials connected with the various departments of the Corporation. It was stated that the tokens had been used otherwise than for the Corporation purposes. The committee decided that the tokens should still be given out, but on condition that they were not used on Sundays, and only when the bearers were on Corporation business.

Hythe.—At a meeting of the Town Council a letter from the Traction Corporation was submitted, offering to construct a tramway on the Kingsland system through Hythe, Folkestone, and Sandgate. The company estimate the cost at £110,000, which would have to be raised by the local authorities. It is suggested by the company that the capital cost of a generating station should be avoided by taking energy from the local supply company, provided that it can be obtained at a cost not exceeding 1d. per unit.

Isle of Man.—The electric railway which runs from Laxey, in the Isle of Man, to the summit of Manxland's highest mountain, Snaefell, experienced last week the first accident since its formation. An up car had stopped about a mile out from Laxey owing to something having gone wrong with the connections. Two down cars were pulled up in consequence close to the spot, but the driver of a third car, rounding a curve at 12 miles an hour, did not observe the block in time, and his car crashed into the stationary vehicles, which were rushed along the line for a distance of 50 yards. Some of the passengers sustained slight injuries by jumping from the cars.

Bradford.—The sub-committee of the Tramways Committee appointed some time ago to inquire into the management of the city tramways, consequent upon certain criticisms which were made, will shortly present their report. The findings of the sub-committee are declared to be wholly favourable to the Bradford management. Not content with mere investigation of the system of control, the sub-committee have gone far afield in order that they might obtain data for comparisons, and the result is that Bradford comes out exceedingly well. The report is stated to represent the almost unanimous view of the sub-committee.

Swansea.—A fatal accident occurred last week, when Mr. A. E. Elcock, a visitor, fell against one of the Port Tennant trams, and succumbed to his injuries. The car was proceeding slowly, as it had only pulled up 20 yards before, and just as it was passing the man fell against the side of the front of the car, and was knocked back into the road. The wheels did not pass over him, but it was evident that his injuries were serious, and the ambulance was sent for from St. Thomas police station. On the arrival of the police the injured man was unconscious and bleeding freely from the nose and mouth and a wound on the right temple. He was conveyed to Swansea Hospital, where he expired shortly after.

Burslem.—At the meeting of the Town Council it was reported that the Tramways Sub committee had received a letter from the company requesting permission to lay 30 yards of tramway on Chell road, in the borough of Burslem, being a continuation of the Chell-street tramline from the borough of Hanley. It was recommended (*a*) that the extension be allowed subject to all agreements and conditions at present affecting the tramways, and to the roadway between the car rails and the kerb on the west side being paved with suitable setts on a foundation of cement not less than 6in. thick to the satisfaction of the borough surveyor; (*b*) that the tramway company be requested to consider the question of introducing ½d. stages between certain points. The recommendations were confirmed.

Belfast Street Tramways Co.—The secretary of the Belfast Street Tramways Co. has issued a notice stating that the company is now prepared to make a further return of 15s. per share on the ordinary shares, and shareholders may receive the amount due upon surrender of the share certificate at the company's office on Oct. 11 or 12. The final payment cannot be made until some outstanding matters have been settled, and as some weeks must yet elapse before that can be the case, it is considered best to make a further return of 15s. per share, and against this payment the share certificate will have to be surrendered. A cheque will be sent for the final payment per share, with an account of the liquidation, but the amount thereof cannot, it is stated, now be determined. It will, however, be only a small sum per share.

Rochester.—After some correspondence between the Corporation and the Chatham and District Light Railways Co. the latter have agreed to extend their line to Delce Grange a continuation to Borstal being considered a matter for future consideration. Tenders are to be called for at an early date. The town clerk reported the result of his interview with the solicitors for the company as to the points of difference in the draft lease, and it was resolved that the settlements of the points in difference be agreed to with the exception of Clause 21, as to which the committee are of opinion either that a clause should be inserted that no improvements carrying a royalty should be adopted without the consent of the Corporation being first obtained, or, in the alternative, that it should be made clear that the Corporation are not to be bound to take over any such improvements.

Yarmouth.—It has been decided to contribute £2,000 towards the cost of the improvement proposed to be made at the Haven Bridge. A penny fare is to be established between the Upper Ferry and the Barking Fishery Inn, Gorleston. The returns for five weeks ended Aug. 31 show: Receipts—Yarmouth section, £2,620. 6s. 5d., net increase, £99. 19s. 5d.; Gorleston section, £2,240 7s.—total receipts for month on both sections, £4 860. 13s. 5d. Passengers carried—Yarmouth section, at 1d., 413,992; at 2d., 105,427; parcels, 245; workpeople, 585; scholars, 4. Gorleston section, at 1d., 161,955; at 2d., 186,389; parcels, 1,781; workpeople, 3,097; scholars, 96. Aggregate—Yarmouth section from April 1, receipts, £5,522. 17s. 5d.—increase, £237. 4s. 3d.; passengers, 1,140,230—increase, 68 752. Gorleston section from July 4, receipts, £3,310. 9s. 3i.; passengers, 480,243. On Oct. 1 penny fares will be resumed on the Yarmouth trams.

Aberavon.—At a meeting of the Highways Committee last week a communication from the Board of Trade was read stating that the Crown officers had returned an opinion that the power conferred on the Board of Trade by Section 5 of the Tramways Act, 1870, of dispensing with the consent of a road authority included the case of a tramway over the whole of which a local authority had jurisdiction as such, and as to part as road authority also, the remainder of such tramway being within the jurisdiction of an independent road authority. The law officers, therefore, considered that in dispensing with the consent of the Glamorgan County Council in the case of the Aberavon order the Board of Trade were acting with their powers. The Board of Trade will accordingly in any similar case arising in the future rely upon this opinion of the law officers of the Crown, and not be bound by the decision of the Select Committee. As a result of this it was decided to again support the scheme to be brought forward in the next parliamentary session.

London County Council.—At a meeting a few days ago of the South London Protest Committee on the House of Lords Rejection of Tramways over the Bridges, the hon. secretary, Mr. Councillor W. Westcott, announced that a very large number of new supporters had joined the committee. The Hammersmith Borough Council made representations to the Board of Trade and the County Council in favour of the adoption of hardwood as the material for paving between the tramrails, and of the overhead trolley system being adopted on the portion of the tramway in this borough. The County Council replied that they could only accede to the application regarding paving to the extent of using wood in the vicinity of churches and hospitals. As to the overhead system, they did not think their Act would permit of this. The Board of Trade have upheld the County Council. There is a movement among the inhabitants for a service from Cricklewood to the Marble Arch, and a recent canvass of frontagers showed that 70 per cent. were in favour of the scheme.

Mitcham, etc., Tramways.—A good deal of interest is being manifested locally in the tramways for connecting the neighbourhood with Croydon, for which the British Electric Traction Co. obtained powers. There are four tramways involved, two being connected with a line from Mitcham to Sutton, the remaining two relating to the line from Sutton to Croydon. The former will run *via* the Mitcham-road, under Angel Bridge, to Sutton railway station. The Croydon line will pass through Waddon, Wallington, and Carshalton, to some extent on the route followed now by the 'buses, and will terminate at the Grapes, or corner of Benhill-street. Croydon and Mitcham, again, will be connected by tram, so that the schemes will form a complete circle. The company received the Royal assent to their Bills in 1902 and 1903, and the works are to be completed by July, 1907, and August, 1908. The company propose to lay double track throughout, and the Surrey County Council and Croydon Corporation are agreeable, but some of the other local authorities favour a single line, contending that the road is not wide enough for a double track.

Belfast.—At a meeting of the Tramways Committee the electrical engineer reported on the application of the National Telephone Co. for permission to supply 31 of their services by means of overhead crossings instead of placing them underground. He pointed out that the company proposed to use insulated cables in these services, and that being the case the Board of Trade would not insist on guard wires being provided. A letter was read from the Post Office authorities regarding the alterations necessary to the telegraph wires consequent upon the establishment of electric traction, the cost of the work (£399) falling upon the Corporation, and, in view of the fact that the telegraph undertaking will shortly pass into the hands of the Post Office, and the like ruling would then apply to the telephone wires, it was considered by the committee desirable to have the telephone wires put in their proper places before the advent of the new ownership, so they declined to accede to the application of the Telephone Company, but, at the same time, they indicated that they would be prepared to consider any individual case where there may be exceptional difficulty in giving the service.

Portsmouth.—At the meeting of the Town Council Councillor Kimber moved the adoption of the report of the Tramways Committee, recommending that the surplus of £13 530. 9s 3d. shown in the balance sheet be carried to a reserve fund. As an amendment, Councillor Hemingway proposed that £4 000 out of the tramway profits should be allocated to the rates. This, he pointed out, would be one way of alleviating the distress. Councillor Dittman, seconding, remarked that the time had now arrived when the Corporation would do what it promised when it commenced trading. Up to the present the Corporation had only handed over £1,000 to the rates. With regard to the tramways, enough had been done for future generations. Alderman Foster pointed out that large sums of money would have to be spent on the tramways in the future, and he suggested that £3,500 should be the amount contributed, which would be equivalent

Digitized by Google

to a penny rate, while £10,000 might be invested. Councillor Hemingway accepted Alderman Foster's suggestion to make his amendment read that £3,500 should be allocated to the rates. The amendment was put to the meeting and carried by 21 votes to 14.

Bristol.—At the inquest upon Morley Gladstone Monks, aged three, who was killed by an electric tramcar at Kingswood, the evidence showed that the child ran from a shop across the path and into the roadway. A witness stated that the child's left shoulder hit the car underneath the gravel box. Deceased was knocked down and carried along over 40 yards. The driver was seen to apply the brake, but witness did not see him throw any gravel down. It appeared that deceased must have been rolled and pushed about 25 yards by the car, and then disappeared underneath, for when the car eventually stopped he was between the metals near the back wheel. Mr. Sidney E Smith, assistant manager to the Bristol Tramways Company, said that he visited the place of the accident within an hour of the occurrence. He there noticed a quantity of gravel on the track. He afterwards went to the Kingswood depôt, and carefully examined the car. He found the brakes in good working order. Further examination showed that the gate and cow-catcher, etc., were in better condition than any other in the depôt, and why they had failed to act during the accident he was unable to tell. The jury returned a verdict of accidental death. The foreman added that the jury unanimously attached no blame to anyone, but they thought that the company might provide jacks on each car, or at certain distances along the routes, in order to lift up the end of the car in case of an accident such as this one.

New York.—A deplorable accident occurred last week on the Manhattan Elevated Railroad, in which 10 passengers were killed and 40 injured. It was between seven and eight o'clock in the morning that the accident occurred, and the train was crowded with men coming into the city to business along the Ninth-avenue line. At Fifty-third-street there is a switch, which turns the trains, when required, along that street and thence to the Sixth-avenue line. Apparently, the signalman, in error, set the points for the train to turn to the left along Fifty-third-street, instead of proceeding straight ahead down Ninth-avenue, and then, realising that he had made a mistake, suddenly closed the points, turning the second car along Ninth-avenue. There was a moment's strain between the first and second cars, and then the second broke away and turned a somersault over the low parapet into the street below. It fell about 30ft., and landed on its end. The impact was so great that the carriage was smashed and the lower end was driven in, pinioning the occupants in a mass of *débris*. Some of the passengers were killed outright. The third car pulled up with a jerk at the junction, and turned off the line also, but the end caught the corner building across the narrow street, and the car hung balanced between the line and the building. The frightened occupants crawled out of the car, gained the ledge of the railroad, and escaped.

Heywood.—At the meeting of the Town Council last week it was decided that the construction of the Hopwood section of the tramways be proceeded with in conjunction with the tramways from Heap Bridge to the cemetery. An application was received from Messrs. Blackwell and Co. for an extension of time until Nov. 14, 1905, for the completion of the tramways. The reply sent—viz., that an extension until Nov. 14 could only be granted as regards the Hopwood section—was approved. The chairman of the Tramways Committee reported upon the heads of agreement with Rochdale and Bury, which have practically been settled, and which have already been referred to in these columns. Mostly the two agreements were the same, but Rochdale differed from Bury, inasmuch as while the Bury agreement was for three years Rochdale suggested that theirs should be for two years; and Heywood fell into line at once on the understanding that it should be optional for them to conclude the agreement at the end of the two years. One or two details, however, remain to be settled. Heywood contend that the mileage should be taken the nearest way—that is to say, in a direct line from Heywood to Rochdale Town Hall, whereas some of the Rochdale cars ran round by Drake-street. In regard to Clause 8, which reads, "Heywood to pay a proportion of the interest and sinking fund on the capital cost of the two cars," the chairman explained that Heywood would pay interest on the car mileage run in Heywood borough, and sinking fund on two cars, which ultimately should belong to Heywood. If there was any portion of the cost unpaid when their agreement with Rochdale fell through, then Heywood would have to pay that balance, and the cars would become their property on that payment. The agreement continues: "If the agreement is terminated, Heywood to take over the two cars and pay the capital cost less the amount contributed towards the sinking fund." In reply to a question as to when the new cars would run, the Chairman said that the service would probably be in operation by the middle of December, perhaps earlier.

Steel Railway Carriages.—At the invitation of the Brush Electrical Engineering Co. a number of visitors attended at the Metropolitan District Railway car depôt at Mill Hill Park on Monday to inspect the first steel railway carriage constructed in this country. Six steel railway carriages have been running for more than two years on the Central London Railway. These, however, were a product of the United States, but recently the Brush Electrical Engineering Co. undertook to supply an all-steel railway carriage to the Underground Electric Railways of London for trial service on the Great Northern, Piccadilly, and Brompton Railway. The new railway carriage has been built to the designs of Mr. G. C. Cuningham, M.I.C.E., general manager of the Central London Railway, who, it is stated, has been successful in making several important improvements on American practice in the British-made carriage. The new railway carriage is claimed to be superior to the standard wooden car in three respects. The first is its absolute immunity from any danger of fire; the second, a considerable reduction in dead weight; and the third—consequential on the second—consists in the material reduction it will effect in expense of haulage. The Brush Electrical Co. estimate that a saving of about 20 per cent. in the weight of the standard type of wooden railway coach will be effected by the substitution of steel carriages. The steel carriage built by the Brush Electrical Engineering Co. is formed of a steel frame with a body of pressed and riveted steel sheets. The sides have a slight outward curve, and are artistically decorated in red and white. Its length over platforms is 49ft. 9½in., its height from rail to roof 9ft. 5¾in., its interior has a perpendicular of 7ft. 6in., whilst its extreme width is 8ft. 9in. The seating capacity of the car is 54, and its total weight 15 tons 17cwt., against the 21 tons 5cwt. of the Metropolitan District Railway coaches, seating 52 passengers, and the 18 tons 16cwt. of the coaches of the Great Northern and City Railway, seating 58 passengers. The interior sides of the steel coach are faced with non-inflammable wood panelling, but this is likely to be superseded in future deliveries by steel or aluminium sheeting. There is nothing in the appearance of the interior to differentiate it from the ordinary wooden carriage. The Brush Electrical Engineering Co. are now building 18 steel cars from this model for the Great Northern and City Railway Co., whilst the London County Council are inviting tenders for 34 steel cars for the underground tramway from Holborn to the Thames Embankment under Kingsway.

LIGHTING AND GENERAL.

Aldrington.—The electric lighting of the town is now in complete working order.

Blackburn.—The Corporation electricity department have been holding a very successful electrical exhibition.

Govan.—It has been decided that ordinary consumers of electricity be given the alternative of a flat rate of 3½d. instead of 4d.

Hindley.—A sub-committee has been appointed to meet Mr. Hopkinson with regard to the Hindley electric lighting order.

Atlantic Cable Laying.—The cable ship "Colonia" has completed the repairs rendered necessary by her recent grounding off Canso (N.S.).

Anglo-Argentine Tramways Co.—An interim dividend of 3s. per share, tax free, is declared on the ordinary shares, on account of the profits for the year 1905.

Bishop Auckland.—The Urban District Council's electric lighting scheme for the town has been completed. This contract was placed with the old Cleveland Co.

Taunton.—An agreement has been arrived at by the Town Council and the Great Western Railway Co. which necessitates a cable being laid through the latter's property.

Thornaby.—An agreement has been signed transferring the electric lighting order obtained by the Council in 1902 to the Cleveland and Durham County Electric Power Co.

Edinburgh.—The National Electrical Construction Co. have obtained authority to transfer their undertaking to the Musselburgh and District Electric Light and Traction Co.

Direct Spanish Telegraph Co.—The directors have declared an interim dividend at the rate of 4 per cent. per annum, free of tax, for the half-year ended June 30, to be paid on Oct. 2.

Woolwich.—It has been decided to wire several of the Council's houses for the purpose of supplying electricity. The cost will be debited to repairs, and be provided out of the rates.

Electrical and Engineering Science.—Prof. Jamieson, M.I.C.E., etc., of Kelvinside, Glasgow, has resumed his correspondence classes for the winter session. Particulars appear in another column.

Electrical Exhibition.—The Lord Mayor, who will be supported by the sheriffs, has fixed 1 o'clock for the opening ceremony in connection with the electrical exhibition at Olympia on the 25th inst.

Greenock.—The total units of electricity generated at Corporation works during the five weeks of July amounted to 195 921, being an increase of 61,294 units as compared with the corresponding month of last year.

Newton.—The Urban Electric Supply Co. intend to apply for a provisional order for the supply of current to Kingsteignton, and have again asked the District Council's permission, which has again been refused.

Electric Lighting and Heating.—A Parisian journal, *Le Batiment*, 14, rue St. Georges, is opening a competition, to be held between Oct. 15 and Nov. 15, in appliances for the lighting and heating of public and private buildings.

Hampton Court.—The Office of Works are making arrangements for an installation of the electric light not only to the private apartments, but to those parts of the palace to which the public have access. The capital outlay will be about £3,000.

Cradley.—The Empire Electrical Co. propose to apply for an order to supply electricity within the Parish Council's area. The Council at their last meeting agreed to let the matter stand in abeyance until the final settlement between the company and the Halesowen District Council.

Penarth.—The District Council have resolved to convert 80 16-c.p. gas lamps into electric lamps using the Nernst lamp of 32 c.p. which the Penarth Electric Lighting Co. offer to supply and maintain for 3 600 hours per annum at a cost of £2. 14s., as against £2. 14s. 8d. previously paid for gas.

Ossett.—The voting at the last Town Council meeting on the electric lighting scheme, on which it was proposed to spend £8,400, resulted in a tie, and the mayor gave a casting vote in favour of the abandonment of the scheme. It was intimated that if it was possible to upset the vote it would be done.

Stock Exchange.—The committee has ordered the undermentioned securities to be quoted in the official list: Folkestone Electricity

Digitized by Google

Supply Co.'s further issue of £25,000 4½ per cent. first debenture stock; Marconi's Wireless Telegraph Co.'s 251,127 shares of £1 each, fully paid, Nos. 1 to 251,127.

Grimsby.—The Town Council have adjourned the consideration of the report of the Lighting Committee, recommending the extension of the electricity station and plant, at an estimated cost of £9,500, and the approval of the engineer's estimate of £8,500 for mains works, etc., required during the next three years.

Eastern Telegraph Co.—A dividend is announced at the rate of 3½ per cent. per annum, less income tax, on the preference stock of the company for the quarter ending Sept. 30 and the usual interim dividend of 1½ per cent. on the ordinary stock, free of income tax, in respect of profits for the quarter ended June 30.

Removal.—The Electrical Trades Engineering Co. have removed their office from York-place, Baker-street W., to their head office and works, the Crown Electrical Works, Maygrove-road, Brondesbury, London, where all communications should be addressed. Telegrams: Eltrenco, London. Telephone, P.O. 958 Hampstead.

Southwark.—The General Purposes and Electric Light Joint Committees have considered offers from private companies to "deal" with the municipal electric light undertaking, and have recommended that "no action be taken." The question was discussed at the last Council meeting, and finally the report was referred back to the joint committee.

Yarmouth.—Twenty-seven applications for 534 lamps in Southtown having been received, which will yield an income of £200, cables are to be laid from Half-Way House to Southtown Station at a cost of £644. The Council propose to expend £500 in placing 10 arc lamps on the front at Gorleston, to be lighted during July, August, and September, at an annual cost of £67.

Rosario Electric Co.—The directors have declared a final dividend of 3s. per share on the 12,000 preference shares of the original issue, making, with the dividend already paid, 6 per cent. for the year ended June 30 last, and of 9·23d. per share on the 8,000 new preference shares, being the equivalent of 6 per cent. per annum from the dates of the respective calls to June 30 last.

Tunbridge Wells.—Strong opposition will be offered at the next Town Council meeting to the resolution advocating the sale of the electricity undertaking, which is to be moved by Mr. Councillor B. M. Woollan, a leading member of the "Ratepayers' League." It appears that a profit of £4,005 has been made and nearly £3,000 has been placed to the relief of the rates.

Dumbarton.—At the last meeting of the Town Council it was proposed that provision be now made for the future lighting of the principal streets of the burgh by electricity to the extent of laying down mains in these streets, and that the matter be remitted to the Public Lamps and Fires and Bills and Electricity Committee with power. After discussion the motion was withdrawn.

Telegraph to Benin.—The telegraph line has been extended to Benin City, Sapeli, and Warri, and offices for the reception of messages have now been opened at the places named. These offices are under control of and worked by the Southern Nigerian Government, and the charge is 2d. per word above the cablegram price to Bonny, the Nigerian Government undertaking the redistribution.

Swindon.—The consideration of the selection of a site for the erection of the weighbridge at the electricity works stands adjourned for three months. The last monthly report of the electrical engineer shows that the number of consumers connected on Aug. 30 was 365, as against 221 a year ago. The number of street lamps converted up to the present date was 187, as compared with 143 a year ago.

Heywood.—The consumption of electricity for the month of July was 3 182 units, as against 2,943 units for the corresponding period of last year, showing an increase of 239 units. The chairman and vice-chairman have been instructed to report as to what allowance should be made to the staff at the electricity works for extra services being rendered in connection with the laying of the new cable for electric tramways.

Pontardawe.—The Council some time ago decided to ask Mr. John Morgan, Cardiff, to report on a scheme for lighting the populous parts in the Pontardawe area. Mr. Morgan estimated the cost at about £32 000. An offer has been received from the Brynamman Electricity Supply Co. stating they were prepared to light the Caegurwen district at £3. 14s. 3d. per lamp of 32 c.p. per annum. The matter is under consideration.

Lighthouses.—The *Revista Maritima Brazileira* for June, 1905, contains an exhaustive article on lighthouses, illustrated by means of coloured plates, in which a different design is used to designate the colour and character of each light used in the various lighthouses on the Brazilian coast. In a table the distances are worked out at which lights up to 10 000,000 c.p. are visible in clear, medium, and foggy weather respectively.

St. Andrews.—The Electric Supply Corporation on Friday inaugurated the electric light and power scheme for the city. Mr. K. A. Scott-Moncrieff London, the general manager, presided, and Mrs. Murray, wife of the provost, switched on the light. The electricity works at Southfield were afterwards visited, where the method of production and working of the plant were explained by Mr. Drummond, the resident engineer, and other officials.

St. Marylebone.—With regard to the change-over at St. Marylebone referred to in another column, it is explained that to lay down new cables would have cost the Council £400,000, while the replacing of the low voltage installations by high-voltage appliances will cost £70,000. Six thousand houses are affected by the change. It is estimated that altogether 100,000 electric lamps will have to be changed, and about 1,500 electrical appliances of 400 doctors will have to be replaced.

Glasgow.—A meeting was held on Tuesday under the auspices of the National Society of Telephone Employés, at which Mr. Wilson presided. It was stated that there were now some 1,500 members of the society in London, Liverpool, and Manchester. A resolution was passed to the effect that the meeting was of opinion that they should join the Society of Telephone Employés to protect and promote the interests of their class.

Durham.—The Consett Iron Co. are about to provide their Chopwell and Gateshead Collieries with an electrical installation. The current will be generated at the Chopwell Colliery at a pressure of 625 volts, three-phase. Part of it will be raised to a pressure of 5,000 volts and transmitted 2½ miles to the Gateshead Colliery, at which point it will be reduced again to the working pressure of 625 volts. This will be one of the first high-tension installations carried out to the new Home Office rules.

Finchley.—Sanction has been received to the borrowing of £23,360 for electric lighting purposes. In arriving at this amount the Board have deducted the sum of £100, representing the difference between the cost of the cooling tower and deep well (£1,600), which were now omitted, and that of the proposed additional boiler and superheater (£1,500) as desired by the Council, and a sum of £40 for the removal of pumps from their present temporary position to a permanent position in the boiler-house. The loan is to be repaid in 16 years.

Bray.—At the last Urban District Council meeting it was proposed that application be made for sanction for a loan of £2,621 for extensions of a capital nature at the electric lighting works, and that the electrical engineer be instructed to prepare the necessary plans, estimates, and specifications showing the probable amounts required, the same to be forwarded to the Local Government Board with as little delay as possible. After discussion, it was decided that a trading account for three years to March 31, 1905, relative to the electric works be prepared.

Farsley.—The District Council have received an offer from the Yorkshire Electrical Distribution Co., who propose to apply for a electrical lighting provisional order for a supply for lighting at 4d. a unit. The company also offered to guarantee to the Council that the cost of electricity for street-lighting would not exceed 2d. a unit. The District Council have now decided to ask the West Riding County Council to consider the advisability of promoting a Bill whereby the public bodies in their area might join forces to meet the electric demands of the West Riding.

Cardiff.—The South Wales Electrical Power Distribution Co. have complained of the action of the Council's committee in supplying power outside their radius in the case of the Ely Paper Mills. The matter has been referred to the electrical engineer and the town clerk to consider. The Cardiff Property Owners' and Ratepayers' Association have written to the Electrical Committee pointing out the advantage of lighting the roads, etc., in Cathays Park with incandescent gas lamps. When the matter came up for discussion, the mayor remarked that an exhibition on a large scale was to take place at an early date at Olympia, London, where the latest improvements in electrical appliances would be shown. They were anxious to be abreast of the times, but they could not commit themselves to the suggestions made until they had seen the latest in electricity.

Fulham.—The Council have decided to support the Poplar Council in the endeavours *re* wiring of consumers' premises mentioned in another note. Permission has been given during the recess to the Postmaster-General to lay two underground telegraph lines in the borough. The arbitration before Mr. Swinburne, the architect under the electric lighting contract for the baths, relative to the question of damages claimed by the Council from the contractors, the National Electric Construction Co., being in the nature of reimbursement for the costs, damages, and expenses incurred by them by reason of the two fatal accidents in December, 1902, has been held. The arbitrator has until Dec. 31 next to make his award. It is expected that he will make the award in the form of a special case, finding certain facts and stating the questions of law for the opinion of the King's Bench Division of the High Court.

Lewesteft.—During August four new consumers were connected to the mains, representing 228 8-c.p. lamps. One motor was connected during the month. There are now connected to the mains 643 consumers, representing 32 410 8-c.p. lamps. The engineer has been directed to dispose of the Old Harbour cables at the best price obtainable. A joint meeting of the Electric Lighting and Tramways Committees recently discussed the subject of an amalgamation of the Electric Lighting and Tramways Committees, with a view to the reorganisation of the office work now undertaken by the committees' and the accountant's office, and came to the conclusion that there was no advantage in an amalgamation of the two committees, but recommended that the Special Finance (Inquiry) Committee should consider whether some economy can be effected by a rearrangement of the work in the offices of the electric lighting and tramways undertakings and the department of the borough accountant.

Harding Churton Motors.—We have received from Messrs. Harding Churton and Co. copies of their recent revised lists of alternating-current motors. We understand that the makers' works are full of orders, and that among the contracts on hand are the following: the Corporation of Croydon, for three single-phase induction motors of the slip-ring type, to be direct coupled to centrifugal pumps, for the Norwood sewage farm; Messrs. McCorquodale and Co., for installation of two-phase motors for driving their extensive printing works; Messrs. Albion, for the entire driving of their clothing factory; Messrs. Whitley Partners (Leeds), a 45-b.h.p. two-phase motor (the fourth motor supplied); Messrs. Bateman's Machine Tool Co., a 25 b.h.p. two-phase motor (the fifth supplied). Messrs. Harding Churton have also recently supplied their alternating-current motors to the Corporations of Leeds, Sheffield, Huddersfield, Burton-on-Trent, Bristol, the Bournemouth and Poole Electric Supply Co., and others.

Digitized by Google

Swansea.—Mr. A. Ellis, electrical manager, in his last report states that at the end of August the premises of 1,160 consumers were connected to the mains, with a total equivalent of 140,101 8-c.p. lamps. The total at the corresponding period last year was 113,672, an increase of 23 per cent. in total connections. The estimated revenue from street lighting was £633. 7s. 5d., and from private supply £1,435. 12s. 3d., a total of £2,098. 19s. 8d. The estimated revenue for the corresponding month last year was £1,965, the present being, therefore, 7 per cent. more. The Swansea Council recently applied for power to borrow a further £7,000 for extensions in the municipal telephone system. They have received a similar reply as that mentioned in another column with regard to the Brighton extensions, and have deputed the chairman of the Municipal Telephones Committee to confer with the Postmaster-General on the subject.

Epsom.—The total amount of electricity generated during the last quarter was 32,449 units, as compared with 27,199 in the corresponding period last year. Of this amount 26,517 units were sold for private and public lighting, as compared with 22,191 units of last year. The income from public lighting was £336, as against £299, and from private lighting £324, as against £245. A statement of accounts for works costs and income for the quarter showed the expenditure to have been £440. 9s. 11d., and the income £749. 5s. The estimates of income and expenditure of the electric light undertaking for the ensuing six months were: income, £1,679; expenditure, £1 154, which included provision for improving the lighting power of 50 columns by the substitution of tantalum lamps for the 8-c.p. lamps now in use at an increased cost of 12s. 6d. a column, also £40 for eight additional lamps to be erected.

Pembroke.—The Urban District Council have received sanction to the extension of the electric lighting system in the town, and it is understood that the laying of about eight miles of cable will be begun at an early date. In the main streets existing incandescent, electric, and gas lamps will be replaced by powerful arc lights. The scheme further provides for laying down cables for household supply, and possibly for generating power in Sandymount and Sydney-parade districts, and the Shrewsbury, Aylesbury, Sandford, Burlington, and Anglesea roads and adjoining thoroughfares. A number of applications have been received for private installations. The question of further reducing the charge of 4½d. per unit for lighting purposes is also under consideration. The plant at the station now in use will be amply sufficient to meet the proposed extensions. The whole scheme is to be completed long before the international exhibition in Herbert Park takes place.

Cricket.—On Saturday last members of the cricket section of the General Electric Co. Athletic Club from Witton Works, Birmingham, journeyed from Hammersmith to play the annual cricket match with the Robertson Electric Lampmakers. We are informed that although Birmingham brought with them an extra strong team, they finally suffered defeat by 18 runs. The finish of the match was very exciting, the last six wickets of the Birmingham team falling for seven runs. After the game both teams and their friends were invited to dinner at the Brook Green Hotel, where an excellent spread was provided. The chair was taken by the president of the Robertson Lampmakers' Club, Mr. C. Wilson. After the dinner a smoking concert was held, at which several artists, including members of both teams, appeared. The Birmingham contingent left at 12 40 a.m. on Sunday for Birmingham, after a very pleasant outing, with a very good impression of the cricket abilities of their fellow employés at Hammersmith.

Radcliffe.—The amount of electricity generated during July was as follows: lighting section—generated, 6,230 units; used at station, 2,570 units; used in the Council's departments, 108 units; tramways section, 27,187 units. The following amended charges will come in force on Oct. 1—namely: Lighting purposes—for consumption not exceeding 250 units per annum, 5d. per unit; exceeding 250 units, but not exceeding 500 units per annum, 4¾d.; exceeding 500 units, but not exceeding 1,000 units per annum, 4½d.; exceeding 1,000 units, but not exceeding 1,500 units per annum, 4¼d.; exceeding 1,500 units, but not exceeding 2,000 units per annum, 3¾d.; exceeding 2,000 units per annum, 3½d. Power purposes—for consumption not exceeding 60 units per brake horse-power per quarter, 2d. per unit; exceeding 60 units, but not exceeding 125 units per brake horse-power per quarter, 1¾d.; exceeding 125 units per brake horse-power per quarter, 1½d. Heating—2d. per unit. All to be subject to a discount of 5 per cent. if the account is paid within 21 days from date of demand.

Ashton-under-Lyne.—In consequence of the receipt of a letter from the Ashton under-Lyne and District Property Owners' Association, the Local Government Board have written to the Guardians as follows: "I am directed by the Local Government Board to advert to your letter of the 5th ult., in which you apply for an order authorising the Guardians of the Ashton-under-Lyne Union to borrow a sum not exceeding £5,000 to defray cost of electric lighting works at the workhouse. I am directed in the first instance to state that in ordinary circumstances the Board consider it desirable the Guardians should obtain electric light from a public source, rather than they should themselves construct generating works. I am to inquire, therefore, whether the Guardians consider the question of obtaining a public supply of electricity before deciding to instal the proposed works, and, if so, on what grounds they desire to adopt the latter course. I am also to inquire whether there are any special reasons for lighting the new infirmary and part of the workhouse by electricity, seeing that, as the Board understand, these buildings are already lighted or fitted for lighting by gas. In this connection I am to forward for the observation of the Guardians a copy of a communication which the Board have received from the Ashton-under-Lyne and District Property Owners' Association. I am to add that the Board should be furnished with full details as to the works to be covered by the proposed expenditure.—I am, sir, your obedient servant, Noel Kershaw, assistant secretary." The matter has been referred to the Electricity Committee, the chairman of which has stated with regard to getting the current from the public authority that 2½d. per unit was being charged to the infirmary, but by spending the money they now proposed on a complete plant they could manufacture their own electricity at a cost not exceeding 1d. per unit. In that way, therefore, there would be a great saving.

Manchester.—The following statement of work done recently in preparation for the winter's load on the Corporation electricity plant has been presented to the Electricity Committee: At the Dickinson-street station superheaters have been added to the boilers to decrease the consumption of coal and increase the steam capacity of the station. Two 750 kw. turbines have been added, capable of supplying current for both traction and light purposes. Owing to the fact that it is impossible to increase the boiler capacity at that station for want of space, it is intended to receive there a portion of the high-tension three-phase current from the Stuart-street station, and transform it for supplying the city. For this purpose three 500-kw. motor converter sets have been fixed, with high-tension and low-tension switchgear. Bloom-street station is now working to its full capacity, and is pronounced to be in a highly efficient condition. At Stuart-street, the largest station, two 6,000-h.p. sets, forming the extension of the station, have been practically completed, and for a few days one of them has been running on the town load very satisfactorily. The plant in the original station at Stuart-street has been thoroughly overhauled, and together with the six engine sets in use there has been put in a condition for meeting the winter's load. More plant has been installed at several sub stations in order to deal with the increasing demand. Additional balancing machinery has been fixed at Hunt's Bank and Piccadilly, with a view to improving the general distribution of pressure on the network of mains. By far the most important work carried out this year has been the large extension of the underground mains. Many miles of fibre ducts have been laid, by means of which wires for further extensions can be laid without disturbing the streets and inconveniencing the public. Eight new 1in. pressure fibre ducts have been run in various parts of the city from the Dickinson-street station, so that the Corporation is in a position to deal with any increased demand which is likely to be made for a few years to come. Considerable attention has been devoted to improving the system of mains, and steps have been taken to secure the prompt location of faults should they arise. The electric lighting order for Gorton has been taken over, and the greater portion of the mains have been laid in that district, including those necessary for street lighting in Hyde-road, Wellington street, and Cross-street. The reduction in the price of electricity from 5½d. to 4½d. a unit comes into force on Oct. 1, and a very large increase in the demand for current is anticipated as a consequence. Many orders have, in fact, been already given. Laying the new mains has entailed an expenditure of £13,000, and the contracts entered into and work done have amounted to £25,000.

Hammersmith.—The premises of 44 additional consumers, representing a maximum of 1,674 8-c.p. lamps, have been connected to the mains, and 24 consumers have been disconnected. The present number of consumers taking current from the mains is 1,650. Mains are to be extended to supply new consumers at a cost of £150, £130, and £55 respectively. The London County Council have requested that the Borough Council should lay certain proposed electric light mains at a depth of at least 3ft. 6in. below the surface where such mains pass under the route of the tramways authorised to be constructed by the County Council; also that in future the Borough Council should lay all electric mains under the footways in roads where there are tramways or which are likely to form part of tramway routes, or, where it should be necessary to place the mains in the carriageway, to lay them as near to the kerb line as possible. The electrical engineer has reported that at the present time mains were being laid practically in accordance with the suggestions of the County Council, with the exception of the depth below the surface of tramway routes, to which the committee consider there is no objection, and they have agreed to comply with the requests of the London County Council. It has been decided to support the Poplar Borough Council, who are urging upon the London County Council the desirability of inserting clauses in its next General Powers Bill empowering borough councils to wire and fit consumers' premises for the use of electrical energy and to obtain loans for this purpose. The electrical engineer has presented a report upon the advisability of modifying the present system of discounts with a view of encouraging an increased demand for power from the Council's station, in which he points out that, in considering any reduction in the price to be charged for an article, there are several things to be considered, the chief item being competition; in addition, the cost of production, the value of the article, and the amount of business to be done must also be borne in mind; that the present price of 1½d. per unit with restrictions as to the period of use is too complicated, and does not tend to encourage the use of electricity for power as much as he hoped. The system of discounts (although very liberal and lower than the prices charged by adjoining undertakings at the time they were arranged) is now somewhat high. Other systems of producing power have advanced very rapidly during the past year or so, therefore it is necessary that the prices for electricity should be revised in order to encourage the use of the Council's supply for the large amount of power used in the district. That the charges can be further reduced and still show a profit is proved by last year's accounts, wherein the works cost per unit (including power and lighting) is only ·8d. per unit sold to consumers. The actual cost of the power units being very much less than this, say not more than ½d. per unit, a selling price of 1d. per unit will leave a handsome profit providing that sufficient units are sold, but it must be remembered that the output is the governing factor, as a profit of ·25d. per unit on 1,000,000 units is only just over £1,050; and that after very carefully considering this subject he had come to the conclusion that a uniform rate of charge with discounts will meet the

Digitized by Google

circumstances in a more satisfactory manner than any system of maximum demand with restrictions as to the period of use. In consequence, the following resolutions were submitted at a special meeting on Wednesday: "That from and after the reading of the meters at the end of the Michaelmas quarter a uniform rate of 1½d. per unit be charged for electricity supplied for power purposes, subject to the following discounts: on accounts exceeding £10, but not exceeding £25 per annum, 10 per cent.; on accounts exceeding £25 but not exceeding £50 20 per cent.; on accounts exceeding £50, but not exceeding £100, 30 per cent.; on accounts exceeding £100, 33⅓ per cent.; and that in the case of a large consumer whose accounts for power supplies by the Council amount to over £100 per annum special arrangements be made, if so desired by the consumer, to supply current for both power and lighting purposes at the rate of 1½d. per unit less 33⅓ per cent. discount, provided that the amount of current used for lighting does not exceed 20 per cent. of the total consumption per annum, and subject to the consumer entering into an agreement to drive the whole of his machinery by means of the power supplied by the Council for a period of not less than five years."

PROVISIONAL PATENTS, 1905.

SEPT. 11.

13312. Improvements in and connected with telephone exchanges working on the central microphone battery system. Hermann Oppenheimer, 55 Redcross-street, Barbican, London. (Aktiengesellschaft Mix und Genest, Germany.)

SEPT. 12.

13368. Improvements relating to automatic electrical time switches. John Berg and Frank Clemens Wilson, 104, Colmore-row, Birmingham.

13375. Improved means for connecting tubular electrical conduits together and to their fittings. James William Brooks, trading as the Walsall Hardware Manufacturing Company, and Albert Edward Read, 128, Colmore-row, Birmingham.

13380. An improved cut-off attachment for telephones. Edwin Wright, 88, High Holborn, London.

13381. Reversible galvanic battery. Charles Bernard Askew, 55, Chancery-lane, London. (Complete specification.)

13384. An improvement in magnetic motors. Thomas Grainger, Oak Tree, Rogerstone, Monmouthshire. (Complete specification.)

13401. Continuous-current machine with cord winding and reversing poles. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens-Schuckertwerke G. m. b. H., Germany.) (Complete specification.)

13403. Improved incandescence bodies of tantalum wire for electrical glow lamps. Siemens und Halske Akt.-Ges., Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Oct. 13, 1904, being date of application in Germany.) (Complete specification.)

13419. Telephone improvement and relating to. Joseph Skwirsky, 36, Newman-street, London.

13424. An electric plug adaptor. Oliver Zimmer, 82, Mark-lane, London.

13427. Improvements in and relating to apparatus for purification of water by electrical means. James Franklin Lester, 77, Chancery-lane, London. (Complete specification.)

13432. New or improved electric lighting apparatus for use in connection with cycles and the like. Jacob Lewy, 31, Bedford-street, Strand, London. (Complete specification.)

13447. Improvements in electric motor-starting and controlling switches. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

13448. Improvements in controlling means for automobiles. The British Thomson-Houston Company, Limited, 83 Cannon-street, London. (The General Electric Company, United States.)

SEPT. 13.

13459. Improvements in connection with electricity supply systems. George Wilkinson, Tower-chambers, Halifax.

13484. Improvements in electrodes and in methods of making same. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

13485. Improvements in electric fuses. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

13519. Improvements in and relating to electric control systems. The Allgemeine Elektricitäts-Ges., 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Sept. 13, 1904, being date of application in Germany.) (Complete specification.)

SEPT. 14.

13528. Improvements in electric heaters. George Davis, 15, Victoria-street, London.

SEPT. 15.

13620. Improved slow-speed operating mechanism for electric motor starters and like resistance switches. Verity's Limited and Arthur Edgar Gott, 11, Burlington-chambers, New-street, Birmingham. (Complete specification.)

13634. Improvements in devices for mechanically and electrically connecting tubes or conduits to fittings or other parts. George Whitehead, jun., 33, Chancery-lane, London.

13646. An improved ball joint or socket suitable for supporting electric light fittings and for other purposes. Hugo Hirst and John Hillery Collings, 71, Queen Victoria-street, London.

13673. Bracket for carrying a light on the head and electrical fittings for use therewith. Orazio Mullauro, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

13685. An improved electrical alarm for indicating a stoppage or shortage in the cooling water supply of gas-engines. Hans Pastow, 40, Chancery-lane, London. (Complete specification.)

13694. Improvements in and relating to type-printing telegraph transmitters. Frederick Herbert William Higgins, 18, Southampton-buildings, Chancery-lane, London.

13697. Improvements in inspection boxes and fittings for use with steel conduits for electrical purposes. Charles Edward Gunner, "Elmbank," Kemble-road, Waddon, Croydon.

SEPT. 16.

13751. Improvements in and connected with electrical resistances. Michael Chapman and George Luther Stone, 18, Southampton-buildings, Chancery-lane, London.

NOTES.

University College, London.—The work of the engineering school at University College, London, will begin on Tuesday next. The prospectus of the school shows some important developments in its work since last year. The three years' course for students qualifying for the diploma or for the degree in engineering has now been fully organised. In connection with the department of civil engineering and surveying an important new departure has been taken in the form of enlisting the services of eminent engineers in practice for special courses. For instance, Mr. H. Deane, M.I.C.E., is to give a course in railway engineering, and Mr. A. T. Walmisley, M.I.C.E., in waterways, roads, street paving, and tramways. By this means the teaching of the school will be brought into direct touch with present-day practice.

The Institution.—The issue of the *Journal* dated September contains papers on "The Eddy-Current Brake for Testing Motors," by D. K. Morris and G. A. Lister (Birmingham); "Alternating-Current Motors in Industrial Service," by P. D. Ionides (Glasgow); "E.M.F. Wave Forms," by E. A. Biedermann and J. B. Sparks (Students' Section); "The Present Electrical Equipment of the London County Council Tramways," by J. W. Anson (Students' Section); "Application of Electricity to Mines," by A. C. Anderson (Birmingham); "Electric Heating: its History and Development," by A. E. Jepson (Students' Section); and "Equipment of a Generating Station, with special reference to the Chelsea Station of the Underground Electric Railway." Members are reminded that the volume now consists of two volumes annually.

Wireless Telegraphy.—The Berkshire cavalry camp has become a centre of attraction by reason of an installation of wireless telegraphy. The instruments are carried on the body of a cart, to which another cart containing the dynamo can be attached. The apparatus is in full operation, and is connected with an installation at Aldershot. Other stations are being equipped throughout the manœuvre area, and Sir John French is able to communicate from his headquarters with almost any portion of his command. Another account of the utility of the ethergram comes from New York, where members of the Stock Exchange are having wireless telegraphic receivers installed in the tonneau of their motorcars. By this means and a transmitting apparatus installed at the railway station by the Exchange it is stated that they are enabled to conduct their daily business from the open country, communication with Wall-street having been maintained over a distance of 20 miles, which, the report states, may be increased to 50 miles.

The British Association.—The South African party of the British Association are homeward bound on the "Durham Castle," armed with mementoes of every description, from tomahawks and assegais to ostrich eggs and birds' nests. All the members expressed themselves delighted with the tour, but latterly they have felt the effects of the constant travelling. Scarcely had the visitors embarked at Beira, however, than it devolved upon them to return to shore in order to attend a reception by the Governor. Prof. Darwin, in proposing the health of the Portuguese Sovereign, said it was easy to recall the battlefields on which British and Portuguese arms had fought side by side, but science was now devoted to the pacific arts. Senhor Rapozo, president of the Beira Chamber of Commerce, proposed the health of the association, and Prof. Darwin, in responding, acknowledged the cordial reception which Beira had given them. The party subsequently re-embarked in the "Durham Castle," which left in the afternoon. The tour is voted a great success; numbers of papers were read by eminent scientists, various places of interest were visited, in the course of which the party witnessed the opening of the bridge over the Victoria Falls, and, by all accounts, the visit has imparted a decided impetus to education, and especially scientific education, in South Africa.

Over-Bridge Tramways.—It is something of a novelty to find the London County Council and the City Corporation marching hand in hand, but the favourable reception accorded by the latter authority at their meeting this week to the overtures from Spring-gardens in regard to the Embankment tramway scheme suggests that the House of Lords will find themselves confronted with a still stronger case for sanctioning the County Council's scheme when it again comes before them next session. This is the more likely to be the case seeing that since the summary rejection of the measure by the Upper Chamber in the last session of Parliament the London Traffic Commission has reported favourably upon such a scheme. The Corporation have referred to the Bridge House Estates Committee the Council's suggestion that the City authorities should simultaneously introduce a Bill for the rebuilding or widening of Blackfriars Bridge, with power to obtain expert advice, and as there is likely to be another conference on the whole subject between the Council and the Corporation, it is evident that the former body is more determined than ever to gain its object. It is scarcely necessary to remind our readers that since the rejection of the measure some of the borough councils have also assured the County Council of their support, and with the strong expressions of opinion that have been delivered by a substantial portion of the public the Peers are likely to at any rate give the subject more careful attention than was the case last time.

Municipal Economics.—The fourth year of operation of the East Ham Corporation tramways shows a satisfactory result, and, as sometimes happens in such circumstances, the councillors are not of one accord concerning the allocation of profits. The gross surplus was £11,394, and after providing for interest and sinking fund charges, there remains a net balance of £2,612. Now considering that the capital outlay to date totals £156,253, prudence would suggest placing this sum to the depreciation and reserve fund, which course was, in fact, decided upon. At a recent meeting, however, that resolution was rescinded, and the matter was referred to committee to report upon a proposition that a sum equal to a penny rate should be voted to the relief of the general district charge. The advocates of this step refer to the neighbouring borough of West Ham as a justification for the course proposed. We are not sure that the latter undertaking did well to devote such a large sum as £7,000 to the relief of the rates, but the circumstances were somewhat exceptional, since a profit of over £10,000 was made on the first year's working, and the grant to the rates was made after setting aside over £3,000 for depreciation. The sum shown as placed to depreciation and reserve at East Ham for the preceding year is £342, which is not a great deal in relation to the capital outlay, and the Corporation will be well advised to think well before making the users of the trams pay rates twice over, especially as, even from the ratepayers' point of view, such arrangements may prove to be but robbing Peter to pay Paul.

Wages in Electrical Works.—A strike of considerable magnitude has been threatened in the German capital, and Messrs. Siemens and Halske and the Allgemeine

Digitized by Google

Elektricitäts-Gesellschaft, taking time by the forelock, last Friday closed the departments affected, some 8,000 men being placed on the unemployed list. The workmen in these factories contend that, owing to the cost of living having considerably increased, it is necessary to have a minimum wage of 27s. per week. The companies maintain that the ruling prices are too low to permit of an increase in wages of 15 per cent., especially as the working day has been reduced from 10 to 9 hours. They are prepared, however, to grant an increase of 5 per cent., and have intimated their willingness to reinstate the men as far as possible if their representatives withdraw all other demands. At the moment of writing it is not certain whether the offer will be accepted. The situation is of considerable interest to manufacturers in this country, for wages are the determining factor in cost of production, and this has hitherto formed the chief handicap to British manufacturers, the price of materials being pretty much the same in both countries. A few years ago the Kaiser declared Socialism to be "an ephemeral phenomenon,' despite which it is making considerable headway within his realms, with a consequent equalising tendency in the cost of manufacture. The companies in question, however, decided to combat its inroads, for which purpose concerted action was agreed upon. It is difficult to exaggerate the detrimental effect which these conflicts between capital and labour exercise upon a nation's commerce, and the statement in the recent Board of Trade report that, though several disputes of this kind occurred during the past year, they were nearly all settled by conciliatory agencies without cessation of work affords some cause for gratification at home. Later information from Berlin indicates that, instead of coming to an end, the dislocation is likely to extend.

Wolverhampton Tramway Finances.—Alderman C. T. Mander, chairman of the Wolverhampton Corporation Tramway Committee, has indited a somewhat lengthy reply to criticisms upon the form of traction in use in that town and his own predictions as to the profit which would accrue from the introduction of the tramway. He acknowledges that the Lorain surface-contact system consumes ·24 of a unit more energy per car mile than is the case with 39 other undertakings referred to, but points out that even so the total operating costs are ·3d. less. Beyond this it is claimed that the cost of repairing faults is less with the Lorain than the overhead system, and that, apart from æsthetic considerations, the danger to the public is less. The chairman remarks, too, that this additional current consumption is not an unmixed evil, as the Electricity Committee has the benefit of it. This is certainly the case, though it seems a rather doubtful sort of argument when discussing the tramways on their merits. The alderman proceeds to state that the amount spent last year on renewals was something over £3,000, not £4,790, but, as showing the soundness of Wolverhampton tramway finance, he adds that a further sum of £4,790 was charged to renewals account, and that the Tramways Committee have an accumulated reserve of £8,800 in hand to meet renewals of permanent way, etc., which may not need renewal for some years. Mr. Mander also states that according to the standard form of tramway accounts the Corporation made a gross profit for the past year of nearly £16,000 and a net profit of nearly £5,000, while had the system been owned by a company the surplus would have easily permitted of a 5 per cent. dividend after making liberal allowance for depreciation. The alderman's reply is not altogether devoid of an element of self-satisfaction, for which there is some justification, as the Lorain system has not yet proved the dismal failure that some opponents of the surface-contact system predicted, though it renders connection with neighbouring tramways difficult. It was an innovation on the part of the Corporation, which may or may not turn out an expensive one, but it will at least have contributed to a solution of the claims of the various systems; and, meanwhile, Wolverhampton people have the consolation of knowing that they are in a more favourable position than some undertakings using the overhead system.

Mexico.—English manufacturers in quest of new fields have latterly been casting their eyes eastward, but it is not only in the Orient that the merchant may find another outlet for his wares. If he turns to the West he will find the phenomenon of regenerated Mexico scarcely less remarkable than that of awakened Japan, and this journal has joined in the effort to direct attention to that part of the world—a region which, by the way, is already appreciated by our Canadian cousins as well as Brother Jonathan. The great water power of Central America offers great scope for the adoption of electricity, and American capital is taking advantage of the opportunity. One of the latest schemes to be launched from the United States is that of the Mexican-American Power Company, which will erect several electric power plants near the city of Mexico, and build transmission lines for the purpose of providing power for operating industries there and in a number of towns in the vicinity of the power plants. It is one of the largest electrical projects to be undertaken in Mexico, the amount to be invested being estimated at £2,000,000. It is stated that the first instalment of £300,000 in cash has been paid up, and that all preliminary plans are completed for the immediate construction of the power plants. The main plant will be located on the Malinaltenango River, at the foot of the Snow Mountain, near Toluca. Other power plants will be erected on the Meyuce and Tizates Rivers. According to the reports of engineers who have investigated the water supply and fall of these rivers, the three plants will be able to generate not less than 90,000 h.p. The initial plant will have a capacity of 10,000 h.p. The falls in these rivers are so great that it will not be necessary to construct dams or long canals. By digging a short canal the water from the Mallnaltenango River will be dropped into a barranca, or basin, a distance of 820ft., and thus afford the necessary power for the electric generating plant. It is stated that aluminium will be used for the transmission lines. The generating plants will be situated at an altitude of about 10,000ft. In addition to the transmission line to this city, others will be built to Toluca, El Ora, and a number of other towns and mining centres in that part of the country. Until recently outside enterprise has been handicapped by fluctuations in the Mexican currency, but now that a practically settled standard has been adopted this difficulty has been in a large measure overcome, and we hope to see English manufacturers make a larger bid for trade in this quarter.

Rubber.—A recent contribution in one of the dailies supplies some further information anent the rubber-growing industry—an industry whose prospects have been a matter of considerable divergence of opinion lately. It is tolerably clear, however, that it is one of the relatively few branches of commerce in which the supply scarcely equals the demand. This is not entirely because the conditions would not have permitted of greater production—on the contrary, there are large tracts of suitable territory in our equatorial colonies—but rather because the industry has been neglected, or pursued injudiciously. Hitherto the main source of supply has been South America, but latterly Ceylon, the Malay States, and Central America

Digitized by Google

have been looked upon as likely fields. The position in regard to the last-named is a matter of some uncertainty, but an undoubted advance has been made both in Ceylon and the Malay States. At present the yield from those regions bears only a small proportion to the world's production of some 56,000 tons per annum, but trade conditions point to their eventually becoming the headquarters of the industry. Three years ago the rubber grown in Ceylon amounted to no more than seven tons, which last year advanced to 35 tons, but there are now planted in that island and the Malay States some 80,000 acres, estimated to yield by 1911 about 16,000,000lb. Even this represents only 12½ per cent. of the world's present output, which, as already mentioned, is hardly adequate to the demand, and the demand, largely owing to the needs of motorcars and 'buses, is steadily increasing; but a great incentive is afforded to Eastern planters to proceed with the industry apace. Largely through unskilful treatment, the supply from South America is becoming less, besides which the more up-to-date methods employed in Ceylon yield a higher grade of rubber. The Eastern product is found to contain 95 per cent. of pure rubber against 75 or 80 per cent. from that raised in the districts surrounding the Amazon. In addition, the article can be cultivated much more cheaply in the East. An impetus has been given to the industry in Ceylon by the discovery that, contrary to previous theories, swampy land is unnecessary, and this has induced tea planters to undertake the cultivation of rubber with a view to augmenting their profits. The rubber trees serve as a shade for the tea plants, though the results are naturally less favourable than with plantations on virgin soil. The other conditions in Ceylon and Malay are quite favourable, as not only is the rainfall suitable, but land can be acquired upon advantageous terms, and the thick Hindoo population is available for labour, so that a reasonable degree of enterprise should result in the development of a substantial industry.

Technical Education.—The Board of Education have issued a circular containing some interesting information in regard to the advantage which accrues from co-operation between employers and managers of technical institutes. As there is considerable variety in the character and amount of such co-operation, the Board have compiled a table of some typical forms of co-operation as showing what has been found actually possible under present conditions. Perhaps the simplest and most common method of co-operation is that in which the employer pays the fees of employés or apprentices taking an approved course suited to the circumstances of the special industry concerned. In many cases students attending approved evening courses are allowed some reduction on the ordinary hours of work without loss of pay. This plan has been extensively adopted, and students have been enabled to attend such classes from about two hours per week to as much as six months in the year in special cases. The care exercised in the selection of the students has, naturally, to be increased as the concession increases. Many large engineering firms employing a number of apprentices make arrangements for their attendance one day per week, or two half days per week, or two or three hours one afternoon or early morning per week, at an approved course of instruction at a technical school. These arrangements are found to work admirably, but still better results are obtained when the total time thus allowed per week approximates to one working day. In certain cases students who have passed successfully through an approved course of study qualify for an increase of pay, and recognition of increased efficiency is also sometimes marked by preference in the matter of promotion. Occasionally employers, or a federation of employers, have selected a few specially qualified students for scholarships, or maintenance fees while attending a two or three years' full-time course specially arranged to bear on their industry. Very carefully thought out schemes for promoting the higher technical education of selected employés have been prepared in particular cases. Certainly not the least valuable form of co-operation is that found in certain districts where committees of employers keep the curricula of the institutes under observation. Where such committees exist it is found advantageous that some of the members should also be members of the institute committee. Such arrangements facilitate another form of co-operation, as where the employers are satisfied of the value of the instruction given at the school, they will often give a preference to the students in dealing with applications for admission to their works. The Board rightly point out that the development of the bond between technical education on the one hand and the practice and commercial aspect of our industries on the other, is a necessary part of further industrial progress. Financial help from employers is of great assistance, but its value is very largely enhanced where the employers take a personal part in supervising the course of instruction, and, by bringing their own experience to bear, ensure that the studies are directed into the proper groove.

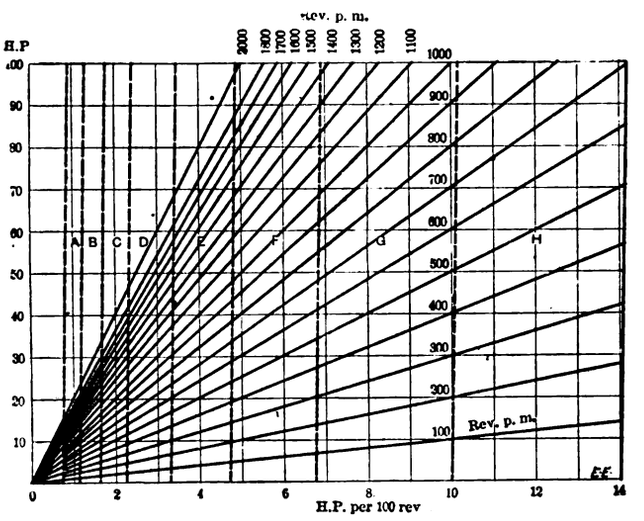
Cardiff Trams.—The report of the borough electrical engineer and tramways manager, Mr. Arthur Ellis, for the year ended March 31 is to hand, and reflects the general tale of trade depression during the 12 months. It also voices the handicap under which the department labours of high capital charges and low fares, in regard to the latter of which the Corporation have decided not to make any alteration. Under these circumstances the undertaking might have done worse than come out with a slight balance on the right side. The total working expenses amounted to £74,301, and loan charges represented £33,438, in addition to which the suspense account absorbed £4,448, leaving a net balance of £20. 17s. 6d., without, however, making any allowance for depreciation. In order to counteract the high capital charges and low fares, the management was compelled to resort to economies in operating expenses, with which object a substantial reduction was made in the car mileage, happily without any proportionate loss of revenue. A considerable saving was also effected in the matter of the working staff, and this was facilitated by the adoption of automatic overhead frogs and point irons, enabling the drivers to work the junction points from the car platforms, thus dispensing with a large number of signalmen and point boys. In regard to costs of operation the Cardiff figure of 5·948d. per car mile compares favourably with such large systems as Liverpool, Manchester, Newcastle, Nottingham, Hull, and Bolton, but the income per car mile does not show to advantage in consequence of the low fares. Mr. Ellis takes the opportunity of reiterating that if the system is to show a fair return on the capital outlay, the fares must be adjusted on a fair basis. He estimates that if these were raised so as to produce another 1d. per car mile on the average receipts, the revenue would be increased by £11,000 per annum. In any case he is strongly in favour of a revision on certain sections, notably the Splott route, where passengers are carried some 2½ miles for a penny. We think the Corporation will be well advised in taking heed of the warning given by the president of the Municipal Tramways Association last year against too low fares, at any rate until a sub-

Digitized by Google

stantial reserve has been accumulated. After investigating the experience of other towns, Mr. Ellis is not inclined to recommend the introduction of a parcels service, especially as Cardiff tradesmen appear to have their own arrangements in this respect. The parcels system is one, we think, possessing considerable possibilities, but it is comparatively young at present, and litigation is pending as to the limits of tramway undertakers' powers in this respect, so that the Cardiff Corporation are perhaps wise in deferring an experiment of this kind. The report contains some interesting remarks in regard to the rolling-stock, the car wheels in some cases having run a total of 78,000 miles, and axle bearings which have been in use for two years are still in good condition. Wear has reduced the diameter of the wheels from 30in. to 26¾in. All these old wheels are being retyred and fitted with deeper tyres, making the diameter 31¾in. In a few cases chilled cast-iron wheels have been tried, but apparently have not given unmixed satisfaction. As the works costs are expected to be further reduced during the current year, an increased balance may be anticipated with some confidence.

Education in South Africa.—The remarks made by the Rev. W. E. C. Clarke to Section L of the British Association, taken in conjunction with the address of Mr. W. Cullen, president of the Chemical, Metallurgical, and Mining Society of South Africa, throw considerable light upon the educational system of Cape Colony and the Transvaal. From the address of Prof. P. D. Hahn to the Education Section of the British Association, referred to in our issue of the 15th inst., it will be noticed that considerable steps have been taken of late years in improving education in the Colony, but the system of primary instruction, which should be the basis of the higher education, appears to still be imperfect. Mr. Clarke gave an interesting *résumé* of the difficulties experienced in the early history of the Colony, when education was pretty much at a discount. A decided advance was made in 1839 by the introduction of the "Herschel system," which gave a stimulus to education, and led to the adoption of the Act of 1865, the basis of the system now in operation. In 1873 a university was established, and a number of high schools have been founded. On the technical side a school of mines was instituted at the South African College in 1896, and the students now complete their course at the Johannesburg Technical Institute. Mr. Clarke considers that the Rhodes scholarships, if made post-graduation scholarships, will not only benefit the holders, but will further higher education. South African education has been gradual of development, and has, perhaps, been a gainer thereby, as it has been the policy of the authorities to benefit by the experience of other countries. One drawback has been the unsatisfactory position of the teacher, and until this has been improved the best results cannot be expected. There are indications that this fact is being recognised. Mr. Cullen had not a very hopeful tale to give in regard to technical education in the Transvaal. He found that, although the inducements offered were very good, the young colonists did not enter the workshops in any numbers, and 90 per cent. of their skilled hands came from oversea. He thought the cause could be traced to the lack of an organised system of apprenticeship, though he was pleased to learn that several private engineering firms had a definite system, which worked excellently. On the mines, however, apprentices were regarded as a nuisance, which is a lamentable state of affairs, and one which, we trust, will be remedied at no distant date. Mr. Cullen quoted the following finding from the report of the commission appointed by the Cape Colony Government: "From the evidence adduced, the commission finds that in almost all professions and trades in respect of which evidence has been given before the commission the more capable and technically trained men have not been trained in this Colony, but have come from other countries; and that a high standard of work in the various trades is hardly attainable by locally-trained artisans owing to the absence of provision for technical education. The absence of any such training debars the Colonial youth from attaining that degree of efficiency which would enable him to compete with the man who has had a technical training elsewhere." It seemed to Mr. Cullen that if this were the state of things in Cape Colony, the Transvaal was in a much worse position. It is consoling, therefore, to learn that the visit of the British Association has imparted a stimulus to education in the Transvaal, and that the establishment of a technical university is probable in the near future. To this Sir Richard Jebb has added his assurance that a keen desire has become manifest in South Africa for a scientific system of education, which, it may reasonably be expected, will have the effect of mitigating the evils complained of by Mr. Cullen.

Motor Rating.—A concise and convenient method of expressing the characteristics of a complete line of motors of one type but of various speeds and outputs is outlined diagrammatically by Mr. C. P. Nachod in the *Electrical World* of New York. In the accompanying illustration the areas A, B, C, etc, correspond to the sizes of frames comprising the line of motors. The radial lines denote speed in revolutions per minute and their ordinates horse-power.



To use the curves, suppose the designer or estimator has an inquiry for a 30-h.p. motor at 1,100 r.p.m. The intersection of the horizontal line passing through 30 h.p. and the line denoting 1,100 r.p.m. falls in the area marked D, whence this is the frame needed. Suppose it is required to find the speed of a motor on an F frame to give 40 h.p. Following the 40-h.p. horizontal until it intersects the line bounding the areas F and G, the intersection is seen to be traversed by the radial line denoting 600 r.p.m., which is, therefore, the lowest speed at which that output could be obtained. Or let it be required to find the horse-power that can be gotten from an E frame with a motor speed of 600. The intersection of the boundary line between E and F with the speed curve for 600 r.p.m. is seen to have an ordinate of 28 h.p, which is the maximum output. It will be seen that in this diagram every motor is represented by a point, whose ordinate is the horse-power, whose position in certain areas is the frame, and whose position on the radial lines is the speed. The boundary lines between the areas are not hard and fast, since one combination of slots and conductors is more

Digitized by Google

effective than another; and also since there are only a limited number of combinations available. When a motor rating falls on or very near a boundary line, that rating cannot be positively assumed, but must be checked by a further calculation of the motor. In constructing such a set of curves for a particular line of motors it is only necessary to know the maximum torque, or, what is proportional to it, the maximum horse-power per 100 revolutions for each size of frame. The output of a motor giving 10 h.p. per 100 r.p.m. at 500 r.p.m. is 50 h.p. Therefore, the speed curve for 500 r.p.m. passes through the point whose co-ordinates are 10 h.p. per 100 revolutions and 50 h p. It also passes through zero, and is a straight line; and is thus completely determined. By noting that at the abscissa 10 the speed curves intersecting the vertical are those of 10 times the corresponding ordinate, the curves can be drawn without calculation. The lines marking the frame areas, denoting the maximum horse-power per 100 revolutions, are drawn not quite vertically, but with a slight inclination to the right. This is to allow a higher torque for the higher speeds, due to the improved ventilation, the same heating limit being presupposed for all cases. In all strictness, these may not be straight lines; and the amount of slewing may be difficult to determine. In the line of motors from which these curves were made and used, the motors are so graded that the maximum torques for each frame are approximately in a geometrical series.

Single-Phase Traction. — The first single-phase railway in the southern division of the United States was recently installed between Marietta and Atlanta, at the instance of the Atlanta Northern Railway Company. Energy is generated at a hydro-electric station about 18 miles from the Atlanta terminus at a pressure of 22,000 volts. The trolley line construction is of the general type used in direct-current practice, except that specially heavy insulators suitable for the higher voltage are employed. Within the city limits of Atlanta the trolley voltage is 550, while over all other portions of the railway it is 2,200. A single 4-0 trolley wire forms the entire 2,200-volt distributing system. The trolley wire is suspended from cross spans secured to wooden poles set 90ft. apart on straight track, and about 45ft. apart on curves. The high-voltage trolley line is divided into three sections, each fed from one leg of the three-phase transmission system through oil-insulated self-cooling transformers. There are two transformer stations in each section connected to the same phase, making a total of six stations located approximately 3½ miles apart. The transformer stations are each equipped with one 150-kw. Westinghouse oil-insulated self-cooling transformer, together with the necessary lightning arresters, choke coils, switches, and fuses. The transformer in Atlanta and one in a car-barn near the limit of this city supply the 550-volt section of the trolley, and in order that all transformers may be interchangeable, each is wound so that the secondary voltage of either 2,200 or 550 may be used. As these stations contain no moving machinery, no attendants are required. An occasional inspection of the stations is all that is necessary. The passenger cars are equipped with four Westinghouse 50-h p. motors. The equipment of these cars is notable for its simplicity. The circuit from the trolley passes to an auto-transformer through a double-throw oil switch, which connects it to either one of two taps on the high-tension winding of the transformer according to whether 2,200 or 550 volts is used on the trolley. After leaving the auto-transformer, the circuit passes directly to the ground. The motors may be connected to various taps on the low-tension winding of this transformer, giving five different running points. The connections are made by a drum-type controller, one controller being mounted on each platform. Each controller consists of three drums, one for reversing the relative connections of the field and armature coils of each motor, and the other two, which are directly geared together and operated simultaneously, for varying the voltage impressed upon the motors. The motors are of the conductively compensated type, and are connected permanently two in parallel, the voltage impressed upon each pair of motors being regulated by one of the controller drums mentioned above. The feature of particular interest in connection with the operation of the controller lies in the means employed for preventing sparking in the controller when the connections are changed from one tap to another on the auto-transformer. There are on this transformer six intermediate taps corresponding to voltages 144, 174, 204, 234, 266, and 288 respectively. There are, however, only five running points corresponding to voltages 159, 189, 219, 240, and 277 respectively. It will be noted that these voltages are in each case midway between the ones of the transformer taps. The running voltages are obtained from the neutral point of a so-called "preventive coil"—an inductive coil—which is connected across adjacent taps of the auto-transformer. The segments on the controller drums are so arranged that, in changing the preventive coil from one pair of transformer taps to the next adjacent pair, the circuit is never opened simultaneously at both ends of the coil. In parallel with the preventive coil is connected a "preventive resistance," through one half of which flows the major portion of the current to the motor when the controller is being moved from one running position to another. The preventive resistance is so designed that it takes but little current when subjected to the small voltage between adjacent transformer taps (30 volts), and yet absorbs but little voltage when carrying the full current of the motor. It is evident, therefore, that the motor circuits are never completely opened during operation, and yet there is no direct short-circuit produced between adjacent transformer taps. On the highest running notch of the controller the preventive resistance is cut completely out of circuit, so as to eliminate entirely the loss occasioned by the current due to the voltage between adjacent transformer taps. The freight car is equipped with four motors similar to those used on the four passenger cars with hand control, but in order that this car may be operated on any part of the city system as well as over the company's own tracks, the equipment is arranged for operation on either direct or alternating current. It can be run from a standard 550-volt direct-current trolley, the 550-volt alternating-current trolley in Atlanta, and the 2,200 volt alternating-current trolley between Atlanta and Marietta. To meet these widely different conditions, a combination of rheostatic and voltage control is used instead of pure voltage control as on the passenger cars. The motors are connected permanently, two in series, and the two groups thus formed may be connected to any one of three different taps on the transformer. In starting the car, the motors are connected first to the lowest tap, then to the middle tap through a resistance, next to the middle tap without the resistance, then to the highest tap with the resistance in circuit, and, finally, to the highest tap with the resistance short-circuited. With this equipment three different running points are obtained. When operating on direct current, the motors are connected all four in series and rheostatic control only is used. There are thus four resistance points in addition to the "full-on" position.

OLYMPIA.

According to programme, as our excellent friends the Japanese would say, the Electrical Exhibition at Olympia was opened on Monday last by the Lord Mayor. Appropriately enough, the Electrical Engineers' Volunteer Corps provided a guard of honour for the occasion under Captain O'Shaughnessy, and a most serviceable body of men they looked drawn up for the reception, after which an inspection of the exhibition was made, lord mayors and mayors from the provinces and the mayors of several London boroughs taking part. That over, or as much of it as time allowed, there was a pause for the formal ceremony of declaring the exhibition open, and then luncheon. The latter was presided over by Mr. E. Cunliffe-Owen. As for the toasts, little can be said here. They were apparently not considered of great importance, as no provision seems to have been made to facilitate reporting them. We were told to sit where we liked, and soon discovered that meant sitting where we could. "Success to the Exhibition" was proposed by the Lord Mayor, and responded to by the chairman; "The Electrical Industry" was proposed by Sheriff Sir G. Vesey Strong, and responded to by Colonel R. E. Crompton on (behalf of the electrical manufacturers), the Mayor of Hammersmith (on behalf of municipal electrical undertakings), and Mr. W. H. Patchell (on behalf of electric supply companies).

Our first impressions of the exhibition as a whole were distinctly favourable. It is something more than a collection of trade exhibits, containing that element which should render it popular among those who seek information as well as diversion. It appeals, then, not only to the trade, but also to the general public, and the advertisement obtained should serve as a stimulant to the electrical industry. Gas has had its say, and now it is Electra's turn. Gas engineers have flattered the electrical industry by imitations, but their devices would seem unable to stand the test of time. It needs no photometric measurements to show the rapid decrease in volume of light emitted by their imitation arc lamps, for example, whereas the yield of the real article could scarcely be improved upon for constancy. The flame arc especially wants a lot of beating, and will doubtless find readier preference over gas lamps when mean efficiency becomes the recognised standard for comparison. Then, again, the ascendancy of electricity for domestic purposes is brought into prominence by the exhibition—its superior adaptability for artistic effects, its convenience, its cleanliness as a cooking agent and for heating purposes generally—not to mention the advantages which these several attributes bring in train. The average consumer knows little and cares less about improvements tending to reduce the cost of producing electricity; the price charged per metered unit is his starting point, and after that, ways and means of economical use should be (but are not always) his care. Inferior lamps and motors have in numerous instances brought electricity into disrepute. Many complaints, too, may be traced to the practice, through ignorance, of using electric incandescent lamps beyond their economical life. It is to the interest of the whole industry that these causes of complaint should be minimised. Hence the educational value of an exhibition such as the one under notice is not an unimportant consideration. At Olympia the consumer is brought into touch with first-class material and the latest means of effecting economy in the use of electricity. Moreover, he can rely upon competent assistance in selecting the best for his particular purpose.

But apart from the purely business point of view, the exhibition is, as we have said, an attractive one. What will appeal, perhaps, as much as anything to the casual visitor is the manufacture of Ediswan and Robertson incandescent electric lamps in progress. This sight alone would well repay a visit. Then there are other popular items, such as electric cooking, which cannot fail to draw crowds—not to mention good music and entertainments of a supplementary character. We have never seen an exhibition more complete on the opening day. Practically there remained nothing to do but clear away a few packing cases and a litter of paper here and there. Complaint was certainly made as to the lack of an adequate supply of current for power purposes, but it was the ear rather than the eye that was conscious of this deficiency. Such unreadiness on the part of the management is to be deplored, but should be capable of speedy remedy—the hum of motors must be added.

The exhibition affords an exceptionally good opportunity of noting the progress made in the various branches of electrical engineering and for reviewing the possible lines of further developments. To draw valuable conclusions in the latter direction, it is necessary to take a general view of the exhibits of a particular class and to see what the most progressive firms are doing. We have arranged for a number of experts to assist us by the preparation of special articles, which will give not only reviews of progress made, but also indicate generally what may be expected from the latest developments. For this purpose many subjects have been selected, and in this week's issue will be found articles on prime movers, direct-current dynamos, electric fittings, and electric illuminants. The experts responsible for these articles have been given a free hand, and their opinions are their own. With these articles as a guide a more comprehensive view of the numerous stands will be possible. We would recommend those of our readers who have not already visited the exhibition to purchase a catalogue of the exhibits before doing so, and to mark on the plan those stands they specially wish to visit. Otherwise the attractions on every hand are so numerous that they may come away without seeing what they desire to do. The catalogue gives a good *résumé* of what is to be seen on each stand. It should also be remembered that lectures have been arranged for several nights each week. This list up to date is as follows, the first lecture commences at 8 p m., and the time for the others will be announced later:

Friday, Sept 29.—"Wireless Telegraphy"; W. DUDDELL, member of Council I.E.E.

Tuesday, Oct. 3.—"Development of the Use of Electric Motors"; Colonel R. E. CROMPTON, C.B., past-president I.E.E., M.I.C.E.

Friday, Oct. 6.—"Domestic Electric Lighting"; J. SWINBURNE, past-president I.E.E., M.I.E.E.

Tuesday, Oct. 10.—"Electricity Meters"; S. Z. de FERRANTI, member of Council I.E.E., M.I.C.E.

Wednesday Oct. 11.—"Electric Heating"; H. J. DOWSING, M.I.E.E.

Friday Oct 13.—"Electric Telegraphs"; A. MARTIN, Postal Telegraphs, Cambridge.

Tuesday Oct 17.—"Electric Arc Lighting"; Mrs. AYRTON, M.I.E.E.

Wednesday, Oct. 18.—"Electric Traction"; W. M. MORDEY, vice-president I.E.E, M.I.C.E.

Friday, Oct. 20.—"Telephones"; F. GILL, member of Council I.E.E.

DIRECT-CURRENT MACHINERY AT OLYMPIA.

BY P. K FRIEDLANDER.

Quite a large proportion of the exhibitors are showing samples of direct-current generators or motors, and although no examples of the largest size are to be seen, there is a fairly representative collection of smaller machines. Great novelty of design or construction is not to be looked for, but sufficient variety still exists to give interest to a survey of the productions of the different firms, and here and there novelties occur which may become the standard practice of the future.

The class of machine which is by far the most commonly met with is the favourite protected type of motor, of which samples are shown by some 30 firms, including Messrs. Siemens Bros., Messrs. Crompton, the Lancashire Dynamo Company, the Phœnix Dynamo Company, the General Electric Company, the Electric and Ordnance Accessories Company, Messrs. Vickers, Sons, and Maxim, the Lahmeyer Electric Company, the Brush Electrical Engineering Company, the Union Electric Company, the Morris-Hawkins Company, etc. These motors have much in common—*e.g.*, the magnets are almost always of the four-pole type with a cast-steel yoke projected so as to form the end protection, laminated pole-pieces, slotted armatures with the "straight out" or barrel type of block winding, field coils taped up and generally without special supporting formers, self-oiling bearings, carbon brushes covering from two to four commutator plates, and a brush gear which, if not absolutely fixed, is at least not intended for adjustment.

Digitized by Google

Variations only occur in such comparative details as the shape of the end covers, the methods of supporting the bearings and the brush gear, the details of the brush gear, and also in the over-all dimensions for a given output.

The four-pole construction is retained up to quite large sizes, such as 200-kw. dynamos, by some makers, but the majority pass to six poles at outputs between 100 kw. and 200 kw. at normal speeds. This question of the number of poles has always been more or less a matter of choice, and the correct number for any particular case is greatly dependent on the peripheral current density or number of ampere conductors per inch adopted. The Continental makers, as a whole, are still in the habit of employing more poles than the average English makers, though not necessarily with any consequent improvement in design or price. The introduction of high-speed turbo-dynamos (which, by the way, are unrepresented at the exhibition), of course, tends to reduce the number of poles employed for a given output, in order that the number of magnetic reversals and the core losses may be kept down, and here four poles are found sufficient even for the largest sizes made.

Another cause which will tend to keep the number of poles down is the rapid introduction of reversing or commutating poles, for these more or less remove the limit in the ratio of armature ampere-turns to field ampere-turns previously fixed by sparking considerations. The general

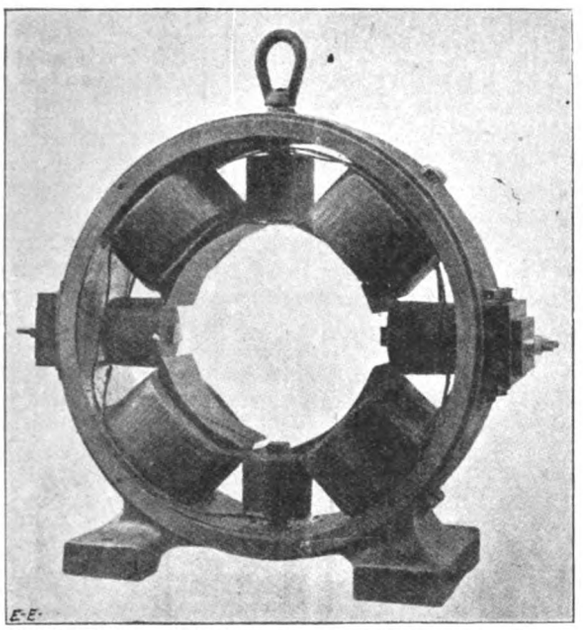

FIG. 1.—Field Frame of a Phœnix Dynamo with Commutating Poles.

action of such poles has been understood for quite 20 years, but it is only during the last two or three years, especially in connection with turbo-dynamos, that they have been at all generally adopted. They offer the very definite advantages of permitting much higher values of the reactance voltage—in other words, fewer commutator plates—to be employed and of compensating for the armature reaction at the commutation point, and so avoiding sparking with fixed brushes over an almost unlimited range of current or speed variation. If the simple reversing poles are replaced by the more elaborate compensating windings of the Dè i or Ryan pattern, as adopted by Messrs. Parsons for their turbo-generators, the further advantage of the prevention of all armature distortion is obtained. The increased expense and clumsiness of the last arrangement, however, more than counterbalances its advantages except in certain extreme cases, and the present tendency for ordinary work seems to be towards the use of small series-wound magnet poles springing from the yoke and acting on the armature at points midway between the main poles. Examples of this type of reversing pole are shown at the exhibition by the Phœnix Dynamo Manufacturing Company (Fig. 1), by the Morris-Hawkins Company (Fig. 5), by the British Electric Plant Company, and by Messrs. Lahmeyer, and several other firms are experimenting in this direction even if they do not employ them in their present standard machines.

The arrangement adopted by the Phœnix Dynamo Company will be seen to consist of a small pole whose face is only a fraction (about one-quarter) of the armature length, and is shaped as shown in Fig. 2. In this way the self-induction of the armature coil during commutation is not increased unduly, as it might be if the pole extended the whole length of the armature At the same time the increased area of the pole behind the neutral line (in a

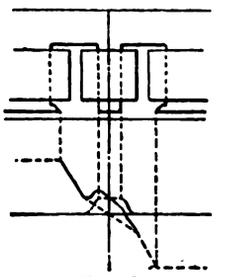

FIG. 2.

dynamo) serves to keep the rate at which the flux is cut (and therefore the reversing voltage induced) constant during the whole time of commutation. The resultant flux curve obtained with a reversing pole equally wide behind and in front of the neutral line is indicated in Fig. 3, whilst the corresponding result with a pole shaped as in Fig. 2 is shown in Fig. 4. A somewhat similar result is sometimes obtained in the machines of the British Electric Plant Company, Alloa, by boring out the reversing pole eccentrically, so as to give a smaller air-gap at one edge than at the other.

The constancy of the reversing field over a fair angular distance is of importance, not only because it permits brush shifting and a consequent adjustment of the compounding effect in dynamos or of the speed in motors, but

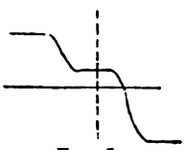

FIG. 3.

also because it is the necessary condition for a straigh commutation curve—*i e*, for a constant rate of change of current in the commutated coil—and this constant rate ensures that no excessive current density will occur at any part of the brush contact area during commutation.

In the Morris-Hawkins machines the cores of the reversing poles are placed near the outer edge of the yoke instead of directly between the main poles, and this avoids any increase in the diameter of the yoke. The main pole-pieces have slanting edges, so that a more extended neutral zone may be produced and the reversing poles (which extend the whole length of the armature) slant correspondingly.

Messrs. Lahmeyer show a variable-voltage direct-current booster fitted with rectangular reversing poles placed midway between the main poles, and extending over the whole length of the armature. Each reversing pole is excited directly by the current of the set of brushes which

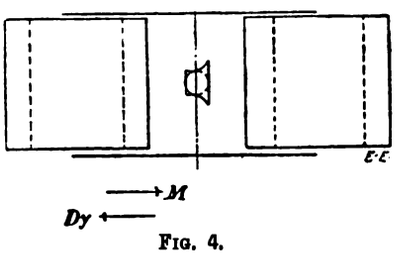

FIG. 4.

it influences. In most cases the peripheral span of the reversing pole is made from 1½ to 3 times the slot-pitch. The use of a very narrow pole-piece, though sufficient for commutation purposes, is not advisable, as experiments carried out by Dr. Breslauer, of the British Electric Plant Company, have shown that such poles are liable to be set in violent vibration by the changes of flux which occur, as slots and teeth alternately pass opposite the pole.

Digitized by Google

Although a well-designed generator or motor can be made to comply with most modern requirements without the use of reversing poles—as is evidenced, for instance, by Messrs. Vickers, Sons, and Maxim's planing-machine motor (Stands No. 19-40) which gives a 3 or 4 to 1 speed variation by shunt regulation without any special devices*—yet this is often at the expense of a somewhat lavish use of copper and iron, and it seems highly probable that reversing poles, or some equivalent arrangement, will shortly become the rule rather than the exception, especially for the higher voltages (over 250 volts) and speeds.

The above machines with reversing poles, perhaps, form the nearest approach to novelty in this branch of the exhibits, but there are many other machines of more or less general interest to which reference might be made. Thus, on Stand No. 94, Messrs. Lahmeyer have a collection of large machinery in operation, including a complete haulage plant driven by a three-phase motor, a motor-alternator set, etc. Messrs. Davey, Paxman, and Co. have one of their high-speed Peache engines direct coupled to a 220-volt, 1,300-ampere Parker dynamo, used for the direct-current supply of the exhibition. Messrs. Crompton, besides a large assortment of smaller machinery and apparatus, show a direct-current dynamo driven by a 30-h.p single-phase motor, and supplying the arc lamps on the stand. Electromotors Limited (Stand 101) show drills, buffing machines, a boot-polishing machine, and other small motor-driven machinery, besides a complete line of protected and enclosed motors fitted with their compact new brush gear, of which a full description appeared in last week's *Electrical Engineer*. Messrs. W. G. Walker and Co. exhibit one of their motor testing air brakes (Fig. 7) in operation on Stand No. 199. This apparatus is supplied in the form of a steel support suitable for clamping to any diameter of shaft in place of the pulley, and fitted with two rectangular aluminium blades, whose distance from the centre is readily adjustable. With the three sets of blades provided motors of from $\frac{1}{4}$ h.p. to 26 h.p. at normal speeds can be tested, the horse-power developed being read off the calibration curves supplied with the apparatus.

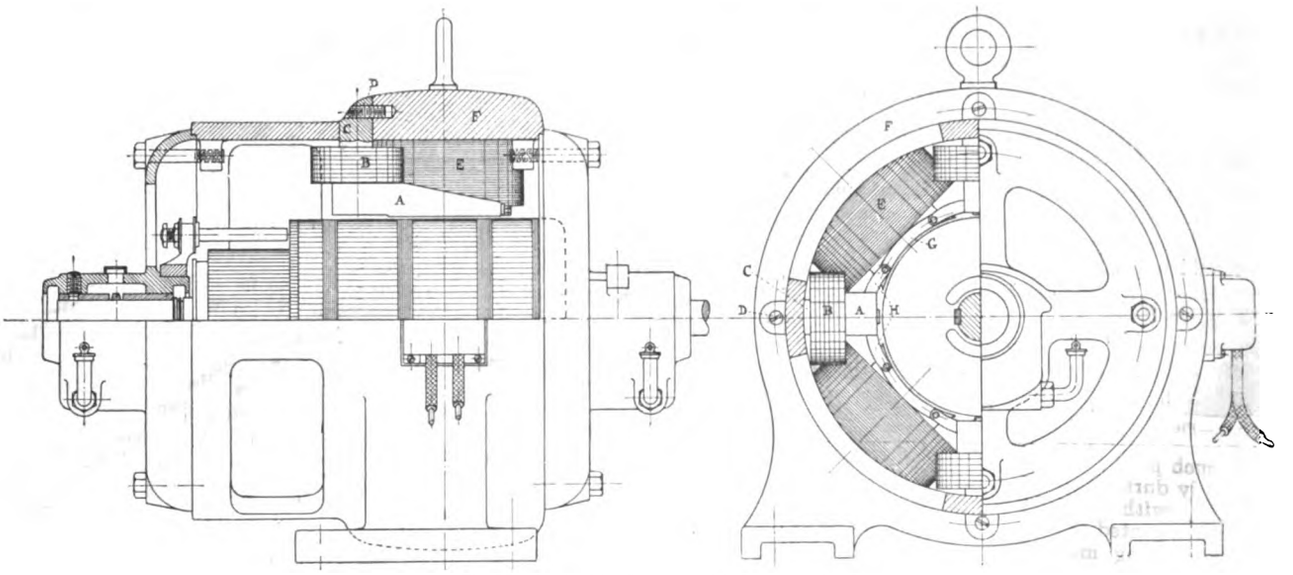

FIG. 5.—The Morris-Hawkins Dynamo with Commutating Poles.

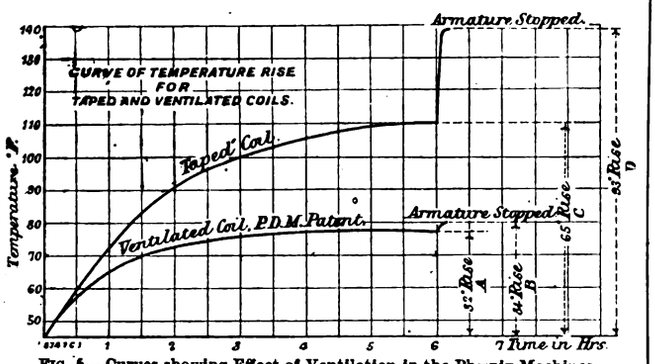

FIG. 6.—Curves showing Effect of Ventilation in the Phœnix Machines.

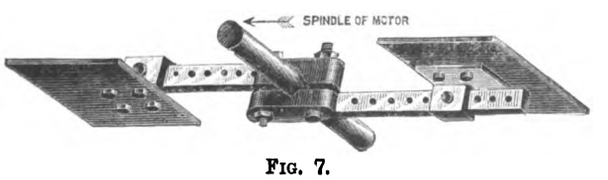

FIG. 7.

On Stand No. 119 the Lancashire Dynamo Company show, amongst an assortment of motors and other apparatus, one of their reversible battery charging and discharging boosters (Turnbull and McLeod patent), a photo of which we reproduce in Fig. 8. This booster has a completely laminated field to allow rapid changes of flux to take place, and is fitted with four field windings: (1) a shunt winding across the booster brushes tending to keep the sum of battery + booster volts equal to the line volts whatever may be the state of the battery; (2) a main winding in series with the battery and the booster armature, compensating for the booster armature reaction; (3) a shunt winding connected across the mains; and (4) a series winding carrying a current proportional to that of the main generators, and acting in opposition to shunt (3). The combined effect of these windings can be arranged either to keep the output of the main generators constant at any desired value, or else to allow the generator current to rise and fall, within certain limits, in proportion to the external load, whilst the battery looks after the whole, or the greater part of, the variations from the normal external load—discharging at times of overload and becoming charged when the external load falls below the normal. The booster shown is capable of giving 120 volts

Digitized by Google

200 amperes continuously, 300 amperes for one hour, or 60 volts 400 amperes for five minutes, all at 800 r.p.m.

Messrs. Wade and Jones show a number of their self-contained lighting sets consisting of an oil-engine (consuming ordinary commercial petroleum) directly coupled to a direct-current dynamo, and forming a convenient combination for country-house lighting or similar work.

It will be seen that on the whole a satisfactory collection of direct-current machinery has been brought together, but it is to be regretted that more of the small motors are not shown actually at work on the machines of the various trades to which electrical driving has now been so widely applied.

RECENT PROGRESS IN ELECTRIC LIGHTING AS INDICATED BY THE OLYMPIA EXHIBITION.

BY FRANCIS H. DAVIES.

Of the hundred odd years which intervene between Davy's discovery of the arc and the present date, the last thirteen—those which separate the Crystal Palace Electrical Exhibition of 1892 from its successor at Olympia—have been by far the most eventful in the history of electric lighting. At that time there existed simply two practical means of obtaining light from electrical energy: the open arc lamp in its various forms and makes, and the incandescent carbon-filament lamp priced at 3s. 9d. and limited in pressure to 100 volts. These, as far as one could see, represented finality—that is to say, in general principles—and few anticipated and fewer still had any conception of the improved and more efficient methods with which we are now so familiar.

Electrical exhibitions have been much in evidence during the present year, and have served a decidedly useful purpose in bringing before engineers and the general public many of the most recent improvements in electrical methods and apparatus. Their scope, however, has naturally been somewhat restricted, as without exception they have been of a local nature, and intended in the first place more as an advertisement for the electricity supply authority than for the manufacturer. The Olympia Exhibition, on the other hand, is essentially one of broad scope, and it therefore offers a considerably better opportunity for noting the many and varied developments in the commercial application of electricity with which the last few years have been so closely associated. To treat of one department only—that of electric lighting. The visitor cannot fail to be struck with the fact that the keynote of all the progress which has been made is efficiency. Better methods of manufacture have been introduced, with the result that the finished product—arc or incandescent lamp—has been cheapened, and entirely new systems of converting electrical energy into light have been devised, with the sole object of lowering the cost to the consumer by giving him the use of more efficient appliances.

In the field of arc lighting there is much, indeed, to chronicle if a comparison be made between existing methods and those of 13 years ago. But the greatest strides of all have undoubtedly been made in comparatively recent years, and it is naturally these which are most in evidence at Olympia and round which the largest amount of interest centres. In arc lamps improvements have taken place along three lines: (1) perfection of feeding mechanism; (2) lengthening of hours of burning without recarboning and adaptation of the single lamp to circuits up to 230 volts; (3) increase of efficiency by the admixture of certain chemicals with the carbon, or by the use of materials other than carbon for the electrodes. In most of the lamps exhibited the first of these improvements is marked. Not only is arc lamp mechanism now, on the whole, much simpler than it was a few years back, but it is also better designed, less liable to derangement, and capable of withstanding comparatively rough usage. The finish, on the other hand, is not so good, and there are evidences in all modern arc lamps of competition and the cutting of cost of production. That this has in no way deteriorated their action is creditable to the designer, who nowadays only provides for fine finish on the parts where it is of practical value, and reduces those parts to a minimum. The arc lamp of to-day compares unfavourably with those of 10 years back with respect to beauty of workmanship, but it is a better burning and much cheaper lamp, if not quite so lasting, and that is what is wanted.

The long-burning enclosed arc lamp is shown in varied forms by several manufacturers. The chief and most valuable improvement, and one which is embodied in most of the lamps exhibited, lies in the abandonment of the inner and air-tight globe, the large and formerly outer globe being made air-tight instead. From the point of view of efficiency this is a considerable advance, since there is thus less absorption of the light. It would appear that the difficulties which formerly existed in this direction have been finally overcome; in which case the enclosed arc lamp may now be deemed nearly the equal of the open arc in efficiency, being at the same time its superior in other directions owing to its well-known characteristics.

The Reason Manufacturing Company are showing lamps of the "Lewis" single-enclosed type which operate—any number in series—without the use of shunt coils. Such lamps constitute one of the most notable advances in arc lighting, since they combine increased efficiency with a large reduction in the number of working parts. Twin-carbon lamps are much in evidence, and are obviously popular. No less than 180 lamps of this type, made by Messrs. Verity, are used for the illumination of the exhibition, and the Reason Manufacturing Company, the Union Electric Company, the Brockie-Pell Company, and Defries and Sons are all showing twin-carbon lamps. The various types differ chiefly in the arrangement of the feeding mechanism, but it is satisfactory to note that simplicity has been the result aimed at in every case—a certain sign of progress when it is combined with good working results.

The Midget arc is rapidly coming into universal use, and is, perhaps, the electric lamp from which the gas companies have most to fear. Here, again, simplicity of mechanism is the keynote of success, and complication of any sort in such lamps cannot be too strongly deprecated. In this respect, midget arcs of British manufacture are far in advance of similar foreign lamps, which usually are more complicated in mechanism and do not provide sufficient radiating surface to get rid of the heat effectively. The claim of the British-made miniature arc to precedence will be obvious if two representative lamps, British and foreign, be compared side by side. There is a great future before the midget arc both for street and interior illumination, and it is evident that manufacturers recognise this.

The well-known lamp of the "flame" type represents the third great improvement in arc lighting, and at Olympia there is a very fine display of these, particularly by the Union Electrical Company, Messrs. Verity, Oliver, Crompton, Braulik, and Arc Lamps, Limited. The improvement which has been effected in the steady running of such lamps is very marked, and in this and other directions they show a considerable advance, particularly gratifying since it has taken but a comparatively short time to effect. Early lamps of this type were distinguished by very few good features beyond the colour of their light, but it is no exaggeration to say that the reproaches which formerly attached to them have to a great degree been removed, and the flame lamp of to-day is a thoroughly commercial product, and should prove a very serious competitor to other forms of lighting. It is particularly interesting to note the ingenious manner in which long burning is effected by the automatic magazine principle of construction. In the "Oriflame" arc of Messrs. Oliver and Co. there are two magazines, one for positive and the other for negative carbons. These are arranged in the upper part of the lamp, inclining to each other in the form of a letter V, so that the arc takes place horizontally between the lower ends of the two carbons. A solenoid in the lamp body acts upon a movable core, which is mechanically connected to the magazines, and serves for striking and regulating the arc as well as for controlling and feeding downwards each pair of carbons consecutively. The "Oriflame" arc lamp burns from 40 to 50 hours, and the carbon ends are discharged automatically one after the other as they are consumed.

Digitized by Google

The efficiency of the flame arc is very high, as may be seen from Fig. 1. This represents the results of a photometric test carried out by the Westminster Electrical Testing Laboratory on three types of arc lamp—a representative enclosed lamp, a representative open lamp, and the "Excello" flame arc of the Union Electrical Company. The mean consumption of these lamps was respectively 485, 476, and 382 watts, and the mean hemispherical candle-power (shown in the diagram by three lines between the candle-power lines) was 338,633 c.p. and 1,325 c.p. respectively.

It has been found impossible so far to enclose flame lamps of any description entirely, owing to the smoke and gases given off by the chemically-treated carbons. This is the direction in which we must look for progress. Magazine methods are both ingenious and effective, but they introduce a certain amount of complication, and cannot be looked upon as a final solution of the long-burning problem. Perhaps no form of electric lamp has progressed so quickly as the flame arc—that is, passed from the stage where it was little better than an experiment and somewhat at a discount, to one where it is almost universally appreciated. The original difficulties which arose out of the formation of slags from the chemically-treated carbons seem to have disappeared, which in conjunction with perfected mechanism is no doubt responsible for the improved performance of the lamps.

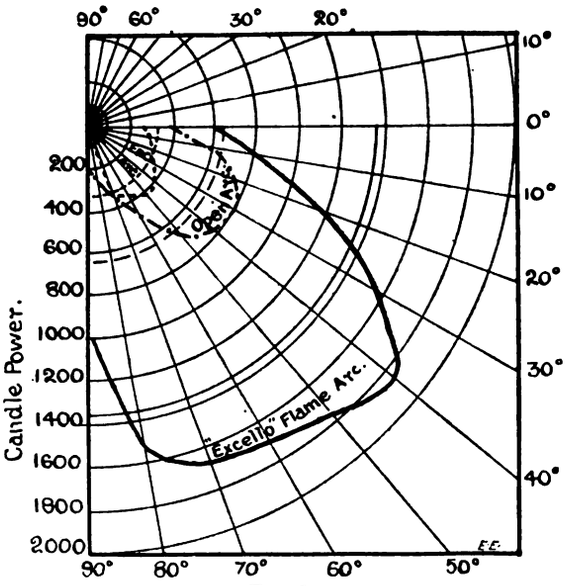

FIG. 1.

The hot-wire type of arc, which is as much in evidence as other recent improvements, dispenses altogether with solenoid control, the expansion and contraction of metal strips with varying lengths of arc, current, and therefore heat, having been substituted as the governing force. Lamps of this description are, of course, suitable for both alternating and direct current circuits, and most satisfactory independent results have been obtained with them. The simplicity of their design and construction is distinctly in their favour, and engineers have not been slow to recognise that such are points of the highest value.

The magnetite arc of Steinmetz is not represented at the exhibition, doubtless due to its present undeveloped state. It is, however, a highly interesting phase of arc lighting, and one of which it is reasonable to expect we shall hear more in the future. The characteristic feature of the magnetite lamp is the use of black oxide of iron mixed with chemicals calculated to increase the life for the negative electrode and copper for the positive. It has been found by experiment that the magnetite pole burns away at the rate of about $\frac{1}{2}$in. per hour, the copper pole being unaffected. The efficiency of the lamp is about twice that of the carbon arc, and lamps have been constructed which by a small sacrifice of efficiency will burn from 500 to 600 hours per one 8in. electrode.

The use of the arc light for blue printing and photographic purposes generally has greatly increased in the last few years. Modern apparatus, compared with the somewhat primitive arrangements that were usual when the arc was first applied to this purpose, show considerable progress, both in the economy of the operations and the quality of the work turned out. Mr. Leonard Shaw is showing a blue-print outfit which possesses some decidedly good points, and, it is claimed, turns out prints of a perfectly even nature with a minimum expenditure of energy in the shortest possible time. The arc lamp, instead of passing slowly from top to bottom of the printing cylinder, and then having to be hoisted and started again, is kept moving quickly up and down, quite automatically, by a small motor. The result is a good diffusion of the light and even prints. Other arrangements provide for the automatic performance of practically all the necessary operations.

The desirability of better diffusion of the light has become recognised in all branches of photographic work to which the electric light is applied. This is specially the case in photo-engraving, where lamps constructed to maintain a very long arc are now often employed. By this means the diffusion is necessarily very much improved and better results attained.

(To be continued.)

PRIME MOVERS AND AUXILIARY PLANT AT OLYMPIA.

BY E. G. BEAUMONT, A.M.I.C.E.

Having regard to the limit imposed by the space available for exhibitors and the variety and number of the purely electrical exhibits, it is not, perhaps, a matter for surprise that those engaged in the construction of engines of all sorts and in the production of important auxiliary plant are not as well represented as could be desired. With few exceptions the engines exhibited are of small powers, but it may be remarked that, on the whole, they are typical of the different classes in general use, and that in one or two instances the internal-combustion engines are of a novel type and design. Apparently, the many prominent firms associated with the construction of steam-turbines are too busily occupied, or have, at all events, for various reasons been unable to provide examples of the type of prime mover now so rapidly coming to the front and claiming so much attention. There is only a notice of the Curtis turbine of the British Thomson-Houston Company, and a reminder in the form of a photograph of the Brush-Parsons type on the stand of the Brush Electrical Engineering Company.

Messrs. W. H. Allen, Son, and Co., Limited, have contributed the largest collection of steam-engines, and the only one in the exhibition representative of the double-acting, enclosed, forced-lubrication, high-speed type. They show one, two, and three crank engines of respectively 30 b.h.p., 130 b.h.p., and 440 b.h.p., the last of these being a three-cylinder compound, and a fine example of an interesting design of engine, of which further particulars will be given later. They are all suitable for steam pressures of 200lb. per square inch, and are of the fixed expansion throttle-governed type with crankshaft governors. A three-throw crankshaft from one of Messrs. Allen's 600-b.h.p. high-speed engines which has been in continuous service for seven years, and has during that time run for 12 hours a day during 300 days per year, exemplifies the remarkable freedom from wear of the running parts of this type of engine when both design and workmanship are excellent. On the journals and crankpins of this shaft there is in some places no measurable wear at all, and the maximum wear on these parts is less than three-thousandths of an inch on a shaft diameter of 6in. The examples of condensing plant shown include a surface condenser, having a thousand square feet of tube surface, designed to deal with 10,000lb. of steam per hour; a three-throw Allen-Edwards air-pump arranged for direct driving by electric motor, and capable of dealing with 25,000lb. of steam per hour, and a vertical steam-driven twin Allen-Edwards air-pump to deal with the quantity of steam condensed by the surface condenser shown. The air-pump barrels of this direct-driven steam set are 10in. diameter, and the compound engine cylinders

Digitized by Google

are 5in. and 8in. diameter, the stroke being 7in. As illustrating the small floor space occupied, it may be mentioned that the over-all length and width are only respectively 4ft. 3in. and 3ft. 6in.

The only steam-engine observed running is the 420-b.h.p. Paxman-Peache engine which is supplying light and power for the exhibition. It is of the three-crank, tandem, compound, single-acting type direct coupled to a Parker multipolar continuous-current generator. Except for detail changes and those necessitated by larger dimensions, it is of the same type as the group of Peache engines which for the past eleven seasons have supplied light and power at the Earl's Court exhibitions, and which form striking examples of the reliability of this design of engine.

On the stand of the Lister Electric Manufacturing Company a two-crank two-cylinder engine of Messrs. Sissons's standard type is exhibited coupled to one of Messrs. Lister's 45-kw. 480-volt multipolar generators. This engine is the only example of the high speed type with variable expansion governor controlled gear, and which, requiring the use of only two cylinders, may be expected to show economical results.

Messrs. Verity's show a little single-crank Reavell engine with a cylinder 5in. diameter and a stroke of 4in., coupled to a 12-kw. multipolar generator, the speed of the set being 500 r.p.m.

Messrs. E. S. Hindley's exhibit comprises several small throttle-governed engines of the opened and enclosed high-speed types. The largest of these is a 50-b.h.p. compound vertical engine with cylinders 7in. and 12in. diameter, with a stroke of 7in.

Of other allied exhibits, to some of which detailed reference will be given in our next issue, those of Messrs. E. Green and Son, Limited, who show their familiar type of economiser with certain detail improvements, and Messrs. McPhail and Simpson, who exhibit an interesting collection of superheater and parts, claim attention.

Messrs. Babcock and Wilcox have, as usual, an interesting stand, and, in addition to models of their standard type of water-tube boiler and specimens of wrought-steel pipework, they also show as a working exhibit one of their silent gravity bucket conveyors with an ingenious pawl driving gear with a semi-human motion which is fascinating. Messrs. Babcock and Wilcox are also responsible for the supply of steam to the exhibition, and have one of their marine type boilers at work. It has 2,218 square feet of heating surface, is fitted with a chain-grate stoker, and there is also a feed-water heater.

The Davies Patent Boiler, Limited, call attention to their segmental or tube element boiler, and among other exhibits show the Premier boiler tubes. The latter may be briefly described as a development of the Galloway tube system, and permits of a considerable increase of the heating surface of boilers of the Lancashire and Cornish types, and an improved evaporative efficiency of boilers fitted with these tubes.

With, for the present, passing reference to the exhibits of accessories such as those provided by the makers of lagging materials and protective coverings, among whom may be mentioned Messrs. Hobdell, Way, and Co. and the Cape Asbestos Company, and to those who, like the Price Patent Candle Company, supply interesting information respecting lubrication and the quality and properties of lubricants of many kinds, and Messrs. Avery, who exhibit their automatic coal-weighing machinery, preliminary mention must now be made of those showing internal-combustion or gas, oil, and light oil or petrol engines.

Messrs. Crossley Bros. show three engines, the smallest of which is a 4¼-b.h.p. oil-engine, which, though small, suffices to show the features of this type. It has a constant measured oil feed to the vaporiser, with governing by varying the number of working strokes. Engines of this type using paraffin or the heavier or crude petroleums are made in sizes up to 50 b.h.p. A 27·5-b.h.p. engine direct coupled to a continuous-current generator and a smaller engine of 16 b.h.p. of the same type are shown in operation; the second of these is being run with ordinary town gas. The larger engine is interesting as the only example in the exhibition of an engine running on producer gas and with its suction plant complete. With the producer gas it develops 21·5 b.h.p., as compared with the 27·5 b.h.p. obtained when running with town's gas of higher calorific value. Welsh anthracite is the fuel used in the producer, and with an engine of this size 0·875lb. is used per brake horse-power hour. At a cost of 21s. 4d. per ton this means that the cost of fuel is but 1d. per 10 brake horse-power hours—a remarkable result. I hope to be able to supply some particulars of the results of running of these engines and their producer plants.

The National Gas-Engine Company also show three engines, one of which develops 20 b.h.p. when supplied with producer gas. With this engine a guaranteed consumption of 1lb. of Welsh anthracite per brake horse-power hour is given, and this with fuel costing 22s. per ton is equivalent to practically 10 brake horse-power hours per 1d. The weight of the engine with flywheels suitable for electric lighting or power work is 98cwt. A small 2-b.h.p. National gas-engine is shown direct coupled to a multipolar dynamo. It is totally enclosed, has a cylinder 4in. diameter, and a stroke of 4½in., and runs at 650 r.p.m. with tube ignition. A 6·5-b.h.p. oil-engine is shown, governed by variation of supply of oil to the vaporiser. There is no positive tube or electric ignition, the charge igniting spontaneously on completion of compression. Regularity of ignition is ensured by a peculiar formation of the vaporiser end of the cylinder and of the piston, and by a communicating port.

The Diesel Oil-Engine Company exhibit one of their interesting engines of 20 b.h.p. At the time of my visit it was running quietly and regularly on a very light load. The engine shown is one of those constructed by Messrs. Sulzer, of Winterthur, and the fuel used is crude Texas oil, a heavy petroleum or petroleum residue. The fuel costs with these engines are, like the suction producer-gas supplied engines already referred to, remarkably low. With crude oil costing 2d. per gallon the consumption is only 0·42lb. per brake horse-power hour, equivalent to 10 brake horse-power hours per 1d. The weight of the engine is approximately six tons.

The two-cylinder 12-16-h.p. Wade and Jones oil-engine exhibited by Messrs. A. P. Wright and Co. is one of those earlier referred to as possessing novel features, which will make it necessary to give fuller particulars in following issues. The whole design is very compact, it is as far as possible balanced, and it is run at 700 r.p.m. Among other interesting features of the design is the means provided of starting up without any of the usual preliminary heating required by the majority of oil-engines by utilising petrol as fuel until the vaporiser has been sufficiently heated by the exhaust gases, when, with the engine running on load, the change from petrol to paraffin fuel may be made. Forced lubrication to all bearings at an oil pressure of 30lb. per square inch is adopted. Ignition is on the accumulator and induction-coil system with sparking plugs—that in common use for automobile petrol engines. The floor space occupied with the engine coupled to a continuous-current Parker dynamo is only 6ft. by 3ft.

Messrs. G. Braulik exhibit on their stand the Hillen-brand gas-engine. On a single base-plate and on a floor space of 6ft. by 3ft. a complete 5-b.h.p. gas-engine and suction producer-gas plant is mounted. The heat contained in the exhaust gases is partly utilised to form and warm the air and vapour on its passage to the producer and to dry the steam required in the usual way. By thus utilising some waste heat, and by attention to a particular degree of cooling of the producer gas, an extremely economical engine is obtained, free from difficulties by deposition or separating out of the tar from the gas and fouling of the valves. The consumption of anthracite fuel is claimed to be only 1lb. per brake horse-power-hour in this small engine.

Other small engines to be hereafter referred to include the two-cylinder enclosed Gardner engine shown by Messrs. Crompton and Co. direct coupled to one of their dynamos, and an extremely compact petrol electric combination, consisting of a four-cylinder 18-24 Blake engine and a four-pole Siemens continuous-current dynamo.

SOME NEW DESIGNS IN ELECTRIC LIGHT FITTINGS AT OLYMPIA.

[BY OUR SPECIAL ARTIST].

Of all the goods displayed at Olympia, perhaps those which appeal most directly to the public are the electric

FIG. 1.

light fittings, by reason of their utility and the gracefulness of their lines. The average visitor, when non-technical, sees many mysterious coils of wire, castings, and rotating

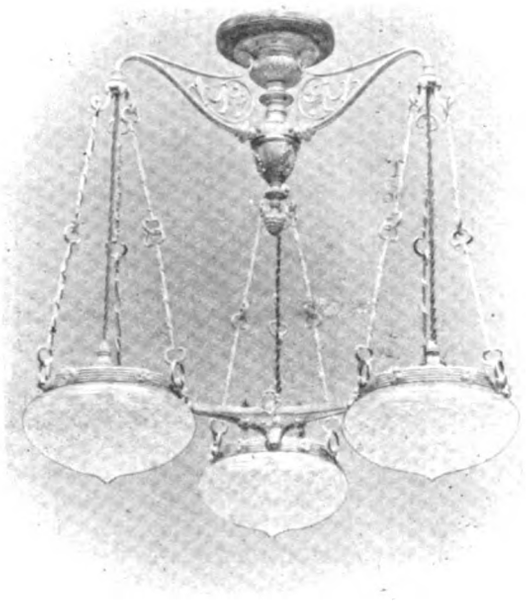

FIG. 2.

masses, but he takes their utility for granted for providing him with the electric light. He does not trouble as to how they do it, but looks on their existence as a means to an end. The electric light fittings are, however, quite different, being the settings for the lamps which give him a healthy and convenient form of light. Perhaps one day every man will be a scientist, and understand the why and wherefore of the generating plant; certain it is that philistinism in art is on the wane, and every man is now (or thinks he is) an artist. The outrageous creations of the Victorian era have been relegated to limbo and the rooms of seaside landladies; the modern man has been educated up to something

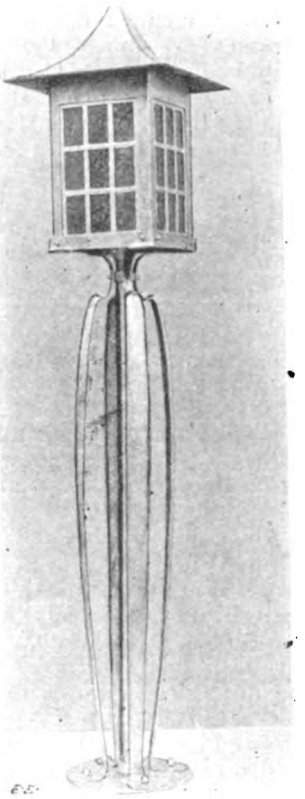

FIG. 3.

higher by his artistic surroundings, that have been evolved out of the brains of a host of designers in furniture, papers, tapestry, and metal work. Having passed through a period of threatened lunacy at the time of the "new art" craze, he now finds himself in a congenial artistic environment, where colours, lines, and ideas are happy and restful.

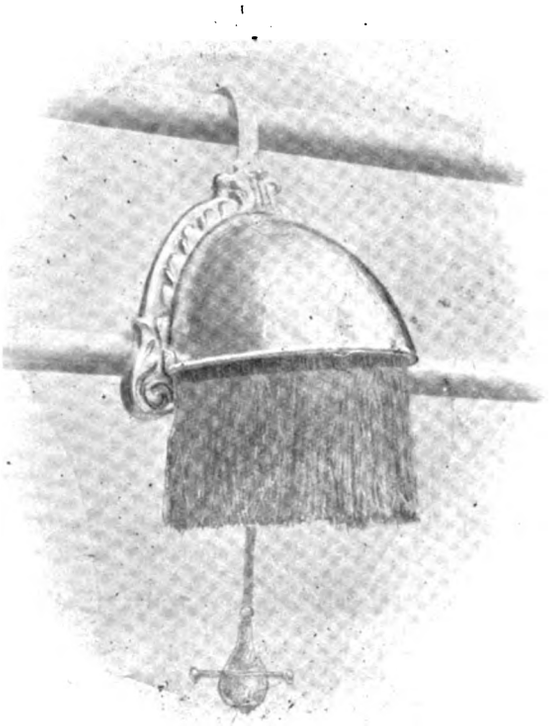
The designers of electric light fittings in this country

FIG. 4.

never developed those mad things that were to be found on the Continent; the temptation during the reaction from the converted gas fitting was no doubt severe, but it passed, and we have now at Olympia an insight into the revival of

Digitized by Google

craftmanship that the last few years have evolved. The following illustrations and remarks describe in a few words only some of the many beautiful designs that are to be



IG. 5.

found. The visitor, be he of the public or the "trade," will do well to see the stands for himself, as no illustrations can reproduce the effects of electric lighting.

Messrs. Verity's, Limited, of King-street, Covent Garden, and Birmingham, have some new and pleasing designs on

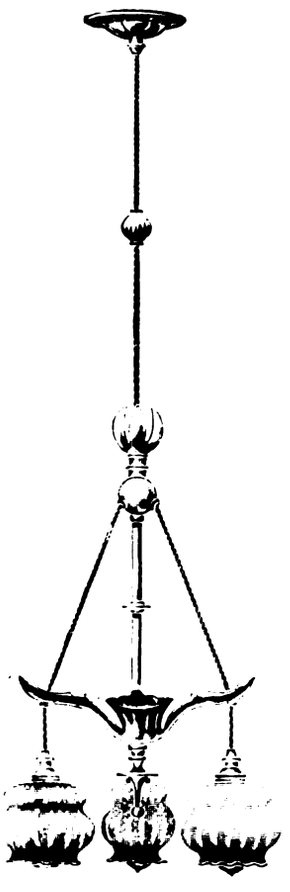


FIG. 8.

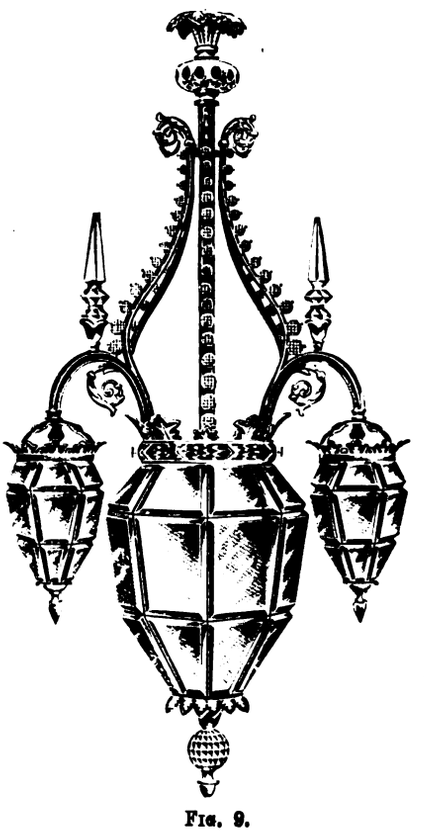

FIG. 9.

view and in their catalogue. For those who treat the electric light as a luxury as well as a necessity, there are fittings which reflect the light on to the ceiling, and thus produce a soft effect unobtainable by other means. Fig. 1 shows such an inverted pendant fitting for one light.

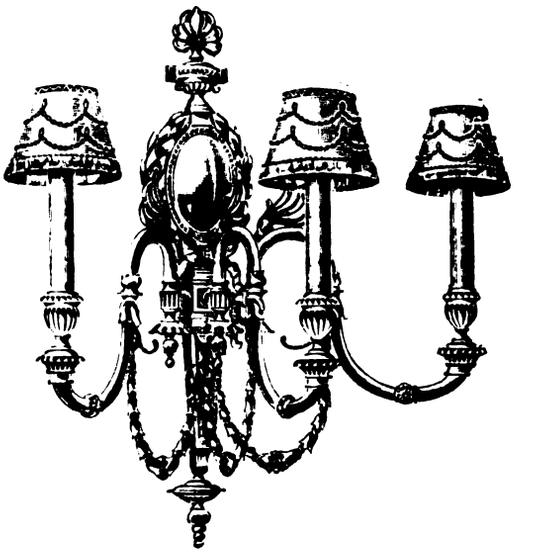

FIG. 6.

Halfway down the cord a metal plate is secured by a grip, and from this depend four chains, which hold a metal bowl of quaint design, with two handles. Fig. 2 shows a more elaborate fitting in the "Adams" style. It is

FIG. 7.

of a very light and graceful design, the three arms that hold the lights being particularly pleasing. The

Digitized by Google

dishes for reflecting the light are shown in cut glass, but can be supplied with satin finish if desired. For those who affect the antique in halls, the newel standard shown in Fig. 3 will commend itself. It comprises four hammered strips of metal, surmounted with a leaded glass lantern. The company are selling a novel patent portable table lamp (shown in Fig. 4), being provided with a knuckle joint at the top, whereby the light may be always vertical; it is also suited for hanging on the wall. The hump in the base contains a universal tumbler switch, which is worked into the design of the fitting. A neat and useful little fitting is that shown in Fig. 5. This has been principally designed for hanging on bedrails, for those who practice the habit of reading in bed. A presser switch is attached by a flexible cord. This fitting is also made without a hood for fixing over doorways, steps, etc.

The stand of Messrs. Falk, Stadelman, and Co., Limited, of Farringdon-road, contains, perhaps, a larger display of fittings than any other in the exhibition, and the designs shown herewith give but a small idea of the selection on view. Fig. 6 shows a three light candle bracket in the "Adams" style, for which there is now a considerable demand. It is finished in ormulu, and may also be had for two lights. A handsome fitting suitable for a study or smokeroom is shown in Fig. 7, which is made of repoussé brass with oxidised silver finish; the spread is only 15in. Fig. 8 shows a pretty little three-light pendant for similar situations; in this the spread is 9in., and the metal work is finished in antique brass. A handsome design of hall fitting for those whose taste inclines towards the massive is shown in Fig. 9. This fitting consists of a cut-glass centre lantern and two side pendants to match. The metal work is richly chased brass, finished ormulu.

(To be continued.)

CALCULATION OF ALTERNATE-CURRENT TRANSFORMERS FOR MINIMUM COST.

BY DR. R. POHL AND H. BOHLE, BRADFORD.

The merit of a transformer is judged by the cost of the active material, the efficiency, the drop, and the temperature rise. The latter may be kept within reasonable limits by using suitable methods of cooling, and the drop by dividing primary and secondary windings into a sufficient number of sections. The problem before us consists, consequently, in constructing a transformer at a minimum cost for a given efficiency. This result has hitherto been obtained as follows: We assumed various inductions, current densities, and core diameters, calculated the number of conductors, weight, and price of the active material, and the losses, and altered one or more of the assumed quantities, until, finally, after much labour, we obtained a design which fulfilled our expectations. This method was naturally tedious and wasteful in time; moreover, it did not give us a guaranty that we had actually obtained the most economical transformer.

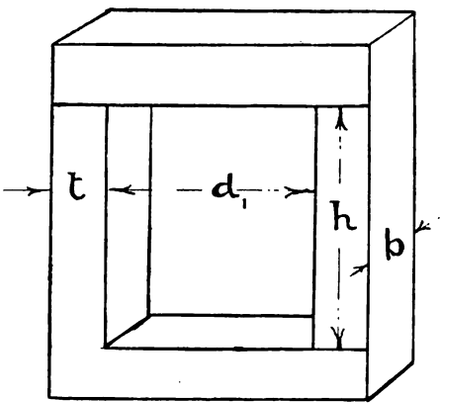

FIG 1.

Undoubtedly, there is only one design for each output which will give the most satisfactory results. The question remains whether a solution of the mathematical problem is possible, and, if so, whether such a method would be sufficiently simple to justify its introduction. The authors believe that in the present article they have described a method which produces the most economical transformer in the first attempt, and which is entirely devoid of mathematical difficulties. For a series of standard designs the greater part of the calculation may be reduced to curves, and one assumption only—that of the efficiency—is sufficient. The latter, which determines also the temperature rise, is easily justified.

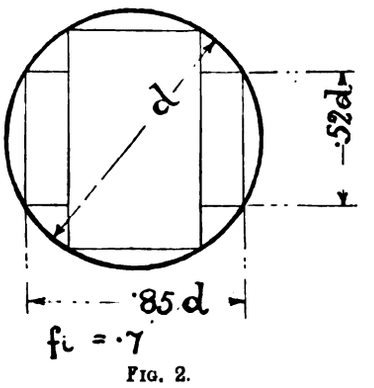

FIG. 2.

If we look through the lists of high-class transformer manufacturers, we find that the efficiency becomes more and more standard, consequently, also, the methods for cooling; because the efficiency is roughly inversely proportional to the losses. For transformers below 50 kilovolt-amperes, natural air cooling is chiefly employed, unless oil is used, principally for insulation purposes. For larger sizes, artificial cooling is almost essential, as otherwise the transformers would become too heavy and costly. The assumption of the efficiency being justified, we may proceed with the mathematical investigations, beginning with the unknown quantities. The same consist of four linear dimensions: t, d_1, h, and b (see Fig. 1), and two specific densities: the current per square millimetre = S, and the number of magnetic lines per square centimetre = B.

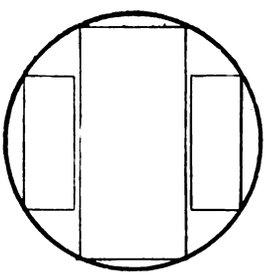

FIG 3.

For a core transformer the relationship between t and b is easily settled. The most suitable shape of the core is evidently a circle, as the ratio of its circumference to area is smallest for such a figure. In practice, however, we cannot make the shape a perfect circle, as we should require sheets of too many different sizes. The latter are limited to two or three from a manufacturer's standpoint, and we employ consequently shapes as shown in Figs. 2, 3, and 4, and which are circumscribed by circles of diameters d centimetres. The effective area of the cross-section of a core may then be expressed by the area of the circle, which

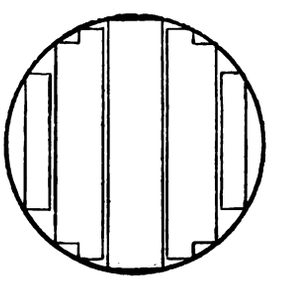

FIG. 4.

Digitized by Google

has to be multiplied by a factor, f_i, called the space factor, and which takes into account the insulation of the sheets and the waste of space due to the imperfect circular shape of the core. The factor f_i will be known for every shape of core cross-section and the kind of insulating material we intend to employ. The two unknown quantities, t and b, are thus replaced by a single one—the diameter, d, of the circle circumscribing the core. The space between two such circles is left for the copper windings. The ratio

$$\frac{\text{area taken up by the copper}}{\text{total available area}}$$

is called the space factor, f_c, of the coils. The same depends upon the primary and secondary pressures and the output of the transformer. For a design of about 50 kilovolt-amperes, and transforming in the ratio of 10 to 1, the value of f_c may be taken from Fig. 5. For larger sizes, f_c will be a little larger, for smaller designs smaller.

Next we consider the most favourable distribution of the losses. It is well known that the iron losses become a minimum when the induction is constant—*i.e.*, when $B_{core} = B_{yoke}$. Similarly, the copper losses are least when the current densities in the primary and secondary coils are equal; or, when $S_1 = S_2$. This does not say how we must distribute the total losses.

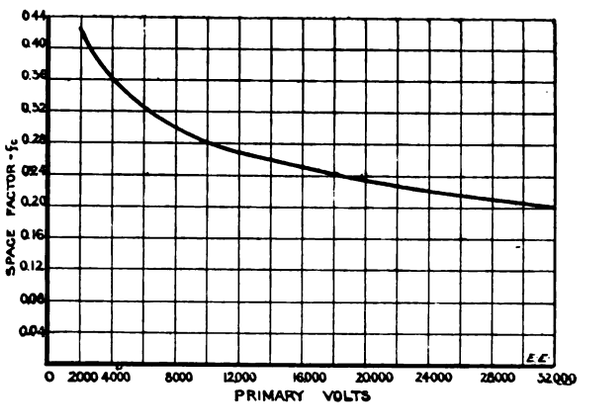

FIG. 5.

Let us assume we are considering a complete transformer. The loss per kilogramme of copper of the primary coil

$$W_{c1} = \frac{I_1^2 r_1}{8{\cdot}9 \times 10^{-5} \times a_1 l_1 w_1},$$

where I_1 = primary current;
r_1 = primary resistance;
a_1 = cross-sectional area of the primary conductor in square millimetres;
l_1 = mean length of a primary turn in centimetres;
w_1 = number of primary turns.

But $$r_1 \frac{\rho \times l_1 \times w_1}{a_1},$$

where ρ is the specific resistance, the value of which at 15deg. C. is about ·0174 ohm per metre length and square millimetre cross-sectional area. Substituting, we find

$$W_{c1} = \frac{I_1^2 \times {\cdot}0174 \times l_1 w_1}{8{\cdot}9 \times 10^{-3} \times a_1^2 l_1 w_1}.$$

Now $$\frac{I_1}{a_1} = S_1 = \text{current density}.$$

Hence $$W_{c1} = \frac{{\cdot}0174\, S_1^2 \times 10^3}{8{\cdot}9} = 1{\cdot}95\, S_1^2.$$

The loss per kilogramme of copper of the secondary winding is found similarly. We have

$$W_c = 1{\cdot}95\, S_2^2.$$

So far we have not taken into account the rise in temperature and the influence of eddy currents in the copper. The effect of the latter is also equivalent to an increase in the ohmic resistance, and which varies between 5 and 25 per cent. It is mainly dependent upon the magnitude of the leakage flux and the size and shape of the conductors. Seeing that S_1 and S_2 should be equal for a minimum copper loss, we may now express the loss per kilogramme of copper by a general equation

$$W_c = K_1 S^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

For a temperature rise of 40deg. C. and a mean supplementary loss of 15 per cent., the value of the factor K_1 is 2·6. Multiplying W_c by the weight, G_c, of the copper conductors, we find the total copper losses of the transformer

$$W_c = G_c \times K_1 \times S^2 \quad . \quad . \quad . \quad . \quad . \quad (2)$$

The iron losses are due to hysteresis and eddy currents. The former vary proportionally to the 1·6th, the latter to the second power of the induction. The loss per kilogramme may be expressed as follows:

$$W_i = K_2 B^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

The factor K_2 is evidently not constant, but decreases with increasing B. For the iron mostly used for transformers, with plates ½mm. thick, K_2 may be taken from

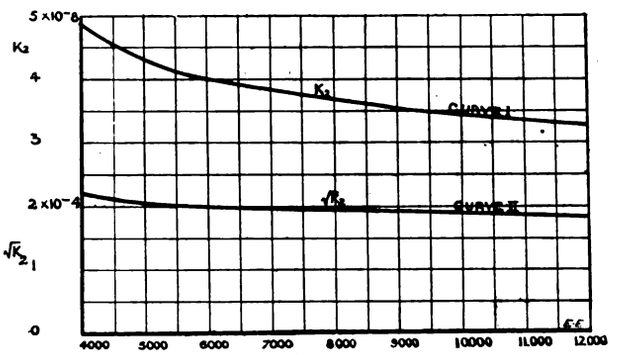

FIG. 6.

Curve I. of Fig. 6. The total iron losses are now given by

$$W_i = G_i \times K_2 \times B^2 \quad . \quad . \quad . \quad . \quad . \quad (4)$$

Let, further, p_c and p_i represent the percentage copper and iron losses respectively, thus that $p_c + p_i = 1$. Then

$$W_c = G_c \times K_1 \times S^2 = p_c \times W_v,$$

and $$W_i = G_i \times K_2 B^2 = p_i \times W_v,$$

where W_v is the total loss. Multiplying and extracting the root, we obtain

$$W_v = \sqrt{G_c \times G_i \times K_1 \times K_2 \times \frac{S^2 B^2}{p_c \times p_i}} \quad . \quad . \quad (5)$$

The power of a given transformer may be expressed by the equation:

$$W = K_0 \times S \times B,$$

where K_0 is a constant involving the number of turns, the frequency, and the cross-sections of the iron and copper. Dividing now the loss by the power, we find

$$\frac{W_v}{W} = \sqrt{\frac{G_c \times G_i \times K_1}{K_0^2}} \times \sqrt{\frac{K_2}{p_c \times p_i}} \quad . \quad . \quad (6)$$

This equation informs us that the percentage loss of a given transformer is a minimum when $\sqrt{\frac{K_2}{p_c \times p_i}}$ is a minimum. If $\sqrt{K_2}$ were constant, which is not the case (see Curve II. of Fig. 6), W_v would be a minimum for $p_c = p_i$—*i.e.*, when the copper losses are equal to those of the iron. It will be seen that the latter should be slightly greater than those of the copper.

By making the assumption that $p_c = p_i$, we do not introduce a great error, as $\sqrt{K_2}$ varies only from $2{\cdot}2 \times 10^{-4}$ to $1{\cdot}8 \times 10^{-4}$ for inductions varying from 4,000 to 12,000. Consequently, for all practical purposes, we may say that the total losses are a minimum when those of the iron are equal to those of the copper. This statement must be modified for transformers which are only occasionally fully loaded; for instance, for transformers used for lighting purposes only. For these it is advisable to make the copper and iron losses as nearly equal as possible for the average load, as far as the drop and the temperature rise of the copper at full load will allow. For the design of such transformers the working conditions must be known beforehand. To reduce the annual losses, we must make the constant ones, the iron losses, as small as is compatible with the average load. For any transformer the working con-

Digitized by Google

ditions of which are known, the distribution of the losses is thus settled. For power transformers we make $p_c = p_i = \cdot 5$, and for lighting designs we reduce p_i and increase p_c.

Of great importance is also the distribution of the weights—*i.e.*, the ratio

$$\frac{\text{weight of iron}}{\text{weight of copper}} = \frac{G_i}{G_c} = K_g.$$

Let P_c be the price of the copper, P_i that of the iron, and p_c' and p_i' the percentage copper and iron prices, such that $p_c' + p_i' = 1$. Let, further, S_c be the price per kilogramme of insulated copper, S_i that per kilogramme of stamped iron sheets, then

$$P_c = S_c \times G_c = p_c' \times P,$$

and

$$P_i = S_i \times G_i = p_i' \times P.$$

By multiplying and extracting the root, we find

$$P = \sqrt{\frac{G_c \times G_i \times S_c \times S_i}{p_c' \times p_i'}}.$$

Consider, now, a transformer the iron and copper volumes of which may be increased or decreased by adding or taking away sheets, respectively conductors, without altering either the mean length of the magnetic circuit or the mean length of a copper convolution (see Fig. 7). Assuming, further, that the current density and the induction are constant, the power of a transformer may be expressed by

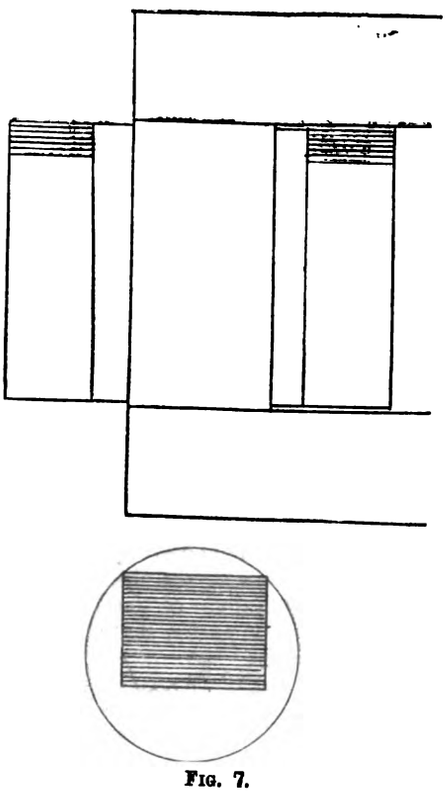

FIG. 7.

$$W = K_a \times G_c \times G_i,$$

whence

$$G_c \times G_i = \frac{W}{K_a}.$$

Substituting this value for $G_c \times G_i$ in the last equation, we obtain

$$P = \sqrt{\frac{W \times S_c \times S_i}{K_a}} \times \sqrt{\frac{1}{p_c' \times p_i'}} \quad . \quad . \quad (7)$$

From equation (7) we find that for a given output the price of a transformer will be a minimum when $p_c' \times p_i'$ is a maximum, or when $p_c' = p_i'$—*i.e.*, when the price of the copper is equal to that of the iron. We may consequently write

$$\frac{G_i}{G_c} = \frac{S_c}{S_i} = K_g{}^{*} \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

The above proof is not very elegant, but its truth may easily be verified by an actual example. Equation (7) holds for all kinds of transformers of the shell and core types, and its truth is independent of the distribution of the losses.

For lighting transformers it may sometimes be found necessary to make K_g smaller than $\frac{S_c}{S_i}$, as otherwise the temperature rise of the copper may become excessive. The ratio $\frac{G_i}{G_c}$ is then probably accurately stated by

$$\frac{G_i}{G_c} = \frac{S_c}{S_i} \times \frac{p_i}{p_c}.$$

This does not influence the price of the transformer to a great extent, as the curve which shows the relationship between $\frac{G_i}{G_c}$ and the price of the transformer is very flat for such values of $\frac{G_i}{G_c}$, which lie between $\cdot 5 \times \frac{S_c}{S_i}$ and $1 \cdot 5 \frac{S_c}{S_i}$.

After having determined the most favourable relationship between the weights of the copper and the iron, the solution of the problem has become possible. For the five unknown quantities we are able to deduct five equations:

I. $F_1 (d\ d_1\ h\ s\ B) =$ output.
II. $F_2 (d\ d_1\ h\ B) =$ iron loss.
III. $F_3 (d\ d_1\ h\ s) =$ copper loss.
IV. $F_4 (d\ d_1\ h) = \frac{\text{weight of iron}}{\text{weight of copper}} = \frac{\text{price of copper}}{\text{price of iron}}$.
V. $S \times B =$ a maximum.

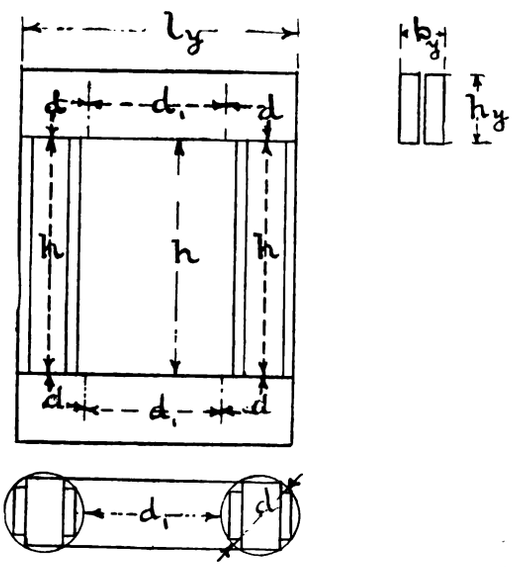

FIG. 8.

The maximum possible, S B, will naturally produce the cheapest transformer. The functions, F, must next be settled. The power of a transformer is given by

$$\text{K.V.A.} = \frac{E_1\ I_1}{1{,}000} = 4 \cdot 44 \times C \times w_1 \times I_1 \times N \times 10^{-11},$$

where E_1 = primary pressure;
C = frequency;
N = flux per core.

But $N = A \times B$, where $A = f_i \frac{d^2 \pi}{4}$ is the effective area of the core, and $I_1 = a_1 \times S$. Hence

$$\text{K.V.A.} = 4 \cdot 44 \times C\ w_1\ a_1\ S\ B\ A \times 10^{-11},$$

or,

$$w_1\ a_1\ S = \frac{\text{K V.A.} \times 10^{-11}}{4 \cdot 44 \times C \times B \times A}.$$

The space between two cores is taken up partly by primary, partly by secondary turns. As the primary and secondary ampere-turns are practically equal, we may write

$$w_1\ a_1\ S + w_2\ a_2\ S = \frac{2\ \text{K.V.A.} \times 10^{-11}}{4 \cdot 44 \times C \times B \times A}.$$

* This law was deducted by R. Pohl in 1900.

Digitized by Google

From Fig. 8, it follows that

$$a_1 w_1 + a_2 w_2 = h\, d_1 f_c,$$

where f_c denotes the space factor of the windings. Substituting, we obtain

$$S B h d_1 d^2 = \frac{2 \text{ K V.A.} \times 10^9 \times 4}{\pi \times 4{\cdot}44 \times C \times f_i \times f_c} = \frac{5{\cdot}7 \times 10^8 \times \text{K.V.A}}{C \times f_i \times f_c} = \alpha \quad . \quad (9)$$

h, d_1, and d are here in centimetres; S in amperes per square millimetre.

Next we consider the weights of the iron and copper. We have

$$G_i = f_i \frac{d^2 \pi}{4} \times 7{\cdot}8 \times 10^{-3} (4d + 2d_1 + 2h) =$$

$$\cdot 012 f_i d^2 (2d + d_1 + h)^* \quad . \quad . \quad (10)$$

By a similar equation we may express the weight of the copper—

$$G_c = 2 \times 8{\cdot}9 \times 10^{-3} f_c \left(\frac{d d_1}{2} + \frac{d_1^2}{4}\right) \pi h$$

$$= \cdot 028 f_c \left(d d_1 + \frac{d_1^2}{2}\right) h \quad . \quad . \quad (11)$$

The values of G_c and G_i may also be deducted from equation (5). We find

$$G_c = \frac{W_v}{S B} \times \sqrt{\frac{p_c \times p_i}{K_1 K_2 K_3}} \quad . \quad . \quad . \quad (12)$$

and

$$G_i = \frac{K_3 W_v}{S B} \times \sqrt{\frac{p_c \times p_i}{K_1 K_2 K_3}} \quad . \quad . \quad . \quad (13)$$

By combining equations (11) and (12), respectively (10 and (13), we obtain

$$S B d^2 (2d + d_1 + h) = \frac{K_3 W_v}{\cdot 012 f_i} \times \sqrt{\frac{p_c \times p_i}{K_1 K_2 K_3}} = \beta \quad (14)$$

and

$$S B \left(d d_1 + \frac{d_1^2}{2}\right) = \frac{W_v}{\cdot 028 f_c} \times \sqrt{\frac{p_c \times p_i}{K_1 K_2 K_3}} = \gamma \quad (15)$$

Considering a new design the efficiency and distribution of the losses of which are known, and the space-factors of which have been fixed, the values of the factors α, β, and γ are determined. The equations (9), (14), and (15) may now be used for the solution of the problem—viz, as follows. In all the equations we have the unknown quantities S and B in the product S B. The latter we treat as a single unknown quantity, and we find then from equations (9), (14), and (15):

$$d_1 = 2 d \left(\frac{\gamma}{\alpha} d - 1\right) \quad . \quad . \quad . \quad . \quad (16)$$

$$S B = \frac{\beta - \frac{\alpha}{d_1}}{2 \frac{\gamma}{\alpha} d^4} \quad . \quad . \quad . \quad . \quad . \quad (17)$$

and

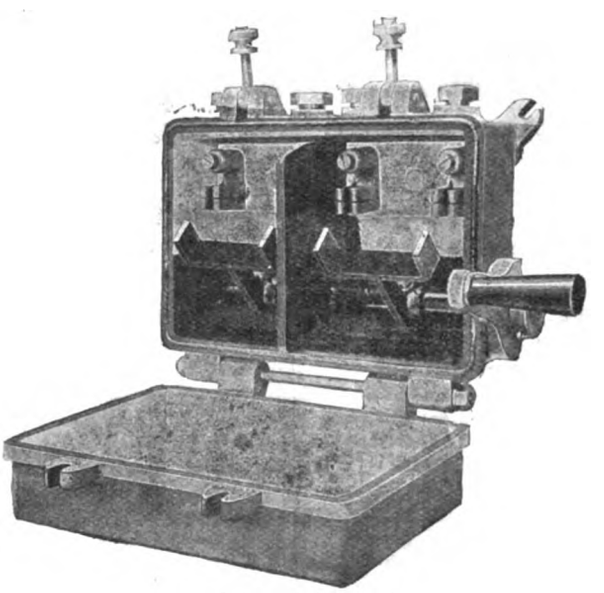
$$h = \frac{\alpha}{S B d_1 d^2} \quad . \quad . \quad . \quad . \quad . \quad (18)$$

(To be continued.)

TRADE NOTICES AND NOVELTIES.

J. and P. Specialities.

The switch shown in the accompanying illustration is of a type manufactured by Messrs. Johnson and Phillips, Limited, Old Charlton, Kent, for mining work, etc. This switch is suitable for circuits up to 600 volts, and is provided with a quick-break movement, durable in every detail. The case is of cast iron, lined with asbestos, and it will be seen that the switch, which is provided with an outside handle, has a long break. It cannot be left in any intermediate position between "on" and "off." Each pole is mounted on a separate porcelain base, a substantial insulating partition being provided between the poles. The spindle passes through a gas and watertight gland into the case. The hinged lid is provided with a rubber ring, so that when closed a perfect joint is made between the lid and box. Suitable rubber glands are provided where the cables enter the box. The holes can be screwed required for gas, simplex, or other threads, to customers' requirements. Details are also to hand of a gas-tight type of direct-current motor starter made by the same firm. This starter is operated through a ratchet and pawl motion, preventing too rapid starting up, arranged so that, although the operator keeps his hand on the starting handle, an overload or absence of voltage breaks the circuit.



Gas and Water-Tight Type Switch.

Catalogues, etc., Received.

Electric Locomotives.—It is well known that Messrs. Mather and Platt, Limited, Salford Ironworks, Manchester, have given considerable attention to the design and construction of electric locomotives, and as these extremely useful adjuncts to mines, collieries, shipyards, and the like are coming more into use, the short illustrated description which the company are issuing of several types supplied by them to fulfil varied conditions of working will, no doubt, prove welcome to many. It is, therefore, with pleasure that we bring it to the notice of our readers.

Armoured Plugs.—An illustrated list which we have received from Mr. A. P. Lundberg, Pioneer Electrical Works, London, N., deals with plugs of various useful types. Among these we notice armoured plugs for use with Lundberg standard "Dot" and "Universal" surface and flush sockets. These plugs are constructed of metal and porcelain only. The brass containing shells are of stout metal, to withstand rough treatment and protect the porcelain parts from injury.

The Electrical Company's Publications.—The Electrical Company, Limited, 121-125, Charing Cross-road, London, W.C., have sent us two sheets illustrating the use of lifting magnets for heavy transport work in ironworks, etc. One illustration shows a square lifting magnet fitted with movable poles, for lifting iron or steel having uneven surfaces or elevations exceeding 1in., while a crane fitted with a compact form of lifting magnet for transporting warm blocks of steel is shown in another. From the same firm we have a sheet dealing with commutators for tramway motors and contact fingers for tramway controllers.

Moving-Coil Instruments.—Three new lists of moving-coil instruments are to hand from Messrs. Evershed and Vignoles, Limited, Acton-lane Works, Chiswick, London, W. These lists deal respectively with sector and edgewise pattern instruments, round-pattern instruments, and portable ammeters and voltmeters. In the last-mentioned a useful type of combined portable ammeter and voltmeter is included. We note that this pattern of instrument has been adopted by the Admiralty for use in H.M. ships. It may be added that these lists are excellently arranged and printed.

Switches.—From Messrs. Ernest F. Moy, Limited, we have a new list dealing with switches of their various standard types.

Finsbury Technical College.—The winter evening classes at this college reopen on Monday, Oct. 2. In the advanced course Mr. H. H. Simmons will lecture on Mondays on alternating-current work, and Prof. S. P. Thompson on transformer design, arc lamps, and dynamo design. In the elementary course Prof. Thompson will lecture on Wednesdays on the magnetic properties of iron and steel, and Mr. P. M. Hampshire on the electric circuit and on galvanometers. The building of the new wing is almost complete, and the equipment of the drawing office and heat laboratory is in progress. It is intended to open these to students at the New Year.

* We assume here that the height of the yoke is about equal to the diameter of the core. Even if this is not absolutely correct, the error is very small.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

Post Free, Payable in Advance.)

Bound Volumes of "THE ELECTRICAL ENGINEER," *containing half-year's copies, bound in Dark-Blue Cloth, Gold-Lettered, price 8s. 6d. New Volume, January to June, 1905 now ready.*

FACTORIES AND THEIR SITUATION.

We regret the position taken by our contemporary *Engineering* on this question because it knows better, and knows that its leading article of last week consists largely of mere clap-trap played to the gallery. Its policy, however, has led to commendation by the *Evening Standard and St. James's*—a combination possessing all the demerits of two papers and none of their merits. It is, however, with the broad teaching of *Engineering* we wish to deal, and to attempt to show the absurdity of that teaching. Of course, the article is cleverly written, too cleverly, perhaps, in that almost every statement of a definite kind is accompanied with exceptions which render the whole indefinite. The text of our contemporary may be gathered from its opening sentence: "One of the causes contributory to the increase of the unemployed in London and other large cities is the *retention* [the italics are ours] of factories *within crowded areas*, and no opportunity should be lost of directing attention to the fact." There is enough that is misleading in these words to warrant a whole book in explanation. What, in the name of all that is good, is one of the most fruitful causes of crowded areas if it be not the erection of factories? And, again, what in the first place induced the erection of factories in the originally uncrowded areas? The retention or non-retention of a particular factory in a particular place is determined by the special circumstances of that case. The writer of the article, we more particularly refer to, assumes that in the first place a factory is dropped upon a particular site by mere chance, that the men concerned in the work of that factory do not know their business, and that it is as easy to move a factory as to fly a kite. On the other hand, let us assume that the men who build and equip factories do know something of their business. Surely, then, before they commit themselves to expenditure they duly consider *all* the circumstances of the case, and finally act in the manner which after this consideration seems best. The one point they cannot altogether consider is what is going to happen half a century in the future. Assume, further, that the capital is found by a limited liability company, and is successful. The reasons for the building of one factory may similarly cause that of a dozen others, each of which may be successful, and the area become crowded. The charges incurred by the local authority of the area arise very largely because the factories are brought into that area. Are we then to contemplate a continuous migration of factories whenever the contributions levied by the authority reach a certain maximum? As regards the unemployed, will it make any difference to the total number of unemployed wherever the factories are situated, provided the total amount of work or the total population remain the same? Still further, will the migration of factories from the crowded areas lead to an equivalent migration of population, but will it not rather lead to an increase in the unemployed in the area from where the migration occurs? Hundreds of similar questions arise in the discussion of the retention or non-retention of factories. The moral to be deduced from our contemporaries' teaching is something to the effect that no factory should be erected within an area where the density of population is greater than a figure not given. We know that Cadbury and Lever and others advocate ideal conditions and ideal villages or towns, but all these are special cases, and not generally applicable. A factory cannot in general be dumped down anywhere. Babbage long ago proved this, as has the natural trend of business; hence we find aggregation of certain manufactures and certain businesses in certain areas. The development of the electrical

Digitized by Google

industry shows how carefully the conditions are considered when opening up a new industry. The various factories are spread over the country, and where placed lead to a greater density of population and a greater local expenditure in the area in which they are placed. The fact of the matter is that *Engineering* in its desire to point out the claims of Kettering—a good, nay, an excellent and laudable object—to the consideration of men about to build factories, has blundered into the farcical view that factories are to be condemned in crowded areas and only supported in sparsely populated areas. The number of the unemployed in crowded areas is a question of quantity of work within that area. The expenditure within given areas is very largely in the hands of those who live within those areas, and if the ratepayers are fools enough to kill the geese that lay the golden eggs they ought to suffer for their short-sightedness. Half of our contemporary's statements we heartily endorse because they are true. Our general condemnation is because text and moral are illogical and untrue.

IMPERIAL NOTES.

Wellington, New Zealand.

Wellington, the capital city of the colony of New Zealand, is situated in the provincial district of Wellington on Port Nicholson, at the southern end of the North Island. It is now the seat of Government, where are the principal parliamentary and Government buildings. On April 1, 1903, its area was extended so as to include the borough of Melrose, which borough consisted of 10 scattered townships or districts adjoining the original city on the south and west The population of the extended city is now about 50,000, its area is 6,174 acres, its unimproved rateable value is £6,611,305, and its capital rateable value £10,840.688.

Public Lighting.—In a previous issue under the above heading we gave an account of the undertaking of the City of Wellington Electric Light and Power Company, Limited, and of the extraordinary success of same. Our special correspondent informs us that the City Council have, with the consent of the ratepayers, recently determined to undertake the lighting of the public street themselves. All lighting wires and cables are now fixed overhead, but it is intended to place the high-pressure wires underground, to place 2,000-c.p. arc lamps on each alternate centre trolley pole, and to light the narrower streets with smaller arc lamps. There are now within the city 33 arc lamps of 2,000 c.p., and over 800 incandescent lamps of 20 c.p. each, but the company also light several suburban districts as far as 3½ miles distant from their station. The incandescent street lamps are charged for at the rate of £3. 10s. each per annum.

Tramways.—The old system of horse tramways was purchased by the Council about four years ago by arbitration at a cost of £20,000. This has been entirely done away with, and a very good system of electric traction has taken its place. There are in all 20 miles of track laid down in double and single lines over about 11 miles of streets, and arrangements are now being made for laying a further length of five miles of single track to the suburbs of Island Bay, Brooklyn, and Kilbirnie in the Melrose district. The overhead trolley system has been adopted, with central poles where the streets are wide enough, with side poles and span wires in part, and elsewhere with single side poles and long bracket arms. It has been necessary to incur considerable expense in raising and altering telegraph, telephone, and electric lighting wires, as these are everywhere in the colony carried overhead, much to the disfigurement of the cities.

Permanent Way —The track is laid to a gauge of 4ft., with standard girder rails weighing 95lb. and 101lb. per yard, on a concrete foundation, and with Chicago copper bond. The pavement of the track in the main streets of the city is of jarrah timber in blocks 5in. deep by 3in. wide, whilst in the outlying districts it is formed with tarred metal surfaced with tar asphalt. The grades are all fairly easy, there being only two or three sharp rises of short length, but which in no case exceed 1 in 12.

Power-House.—The power-house is situated in Jervois Quay, in the centre of the city, and close to the harbour, from which the condensing water is taken. The buildings are substantially erected in brickwork, and cost, with foundations (which were exceptionally heavy and expensive), but exclusive of site, £21,000. The chimney is 134ft. in height, and has an internal diameter of 9ft. 6in. at the base and 10ft. at the top. The plant at present consists of three 300-kw. and one 150-kw. sets. The engines are by Messrs. Belliss-Morcom and the dynamos by the Electric Construction Company. There are three Lancashire boilers, each 30ft. long by 8ft. diameter, with a steam pressure of 160lb. on the square inch, superheated to a total of 500deg. F. Each boiler is of 600 b.h.p., and evaporates 15,000lb. of water per hour. The boilers are fitted with Erith underfeed automatic stokers, and are under forced draught. The coal bunkers will contain 130 tons of coal, which is raised to the stokers by means of an elevator. It is intended to add to this plant at a very early date.

Car-Sheds, etc —The car-sheds, repairing shops, and offices are situated at the Newtown terminus of the system. The shed is built in two bays, each 384ft. long by 52ft. in width, and is of brickwork on concrete foundations, with iron roofs supported centrally on H-iron stanchions. There are eight tracks with inspection pits under, and a traverser at the south end. Adjoining, and at the end of the shed, are the usual workshops, etc., consisting of armature repair shop, fitting shop, painters' shop, blacksmiths' shop, and stores. In the blacksmiths' shop there is provided a wheel press and a small travelling crane, and in the fitting shop the usual gap lathe, grinding lathe, drills, etc. The cost of the car-shed and workshops, exclusive of site, was £19,000, and of the offices which adjoin on the south £3,600.

Cars, etc.—The cars are 34 in number and of various types, some being single-deck enclosed, others, unfortunately, double deckers (which seriously interfere with a quick service), and yet again others of the combination type enclosed at one end and with open cross seats at the other. Fares range between 1d. for a single section and 4d. for the whole distance. Stopping places are defined, and the cars stop only at such places.

Traffic.—The system was only completed in December last, so that the results of a full year's working cannot yet be given; the cars are, however, carrying at the rate of about 12,000,000 passengers per annum, and the revenue per car mile is 11 77d. The number of passengers carried will be found to be very much greater per 1,000 of the population than it is in English towns, but it must be remembered that there are in Wellington practically no poor, the ordinary labourer receiving 8s. per day.

General.—The estimated receipts for the current year from the electric tramways are put down at £68,710, but they will more likely reach about £75,000. The working expenses are placed at £45,145, whilst interest and sinking fund will swallow up £18,000. It will be of interest to note that the working charges in the production of energy amount to only ·7d. per unit, and this notwithstanding the fact that coal costs 17s. 6d. per ton, and the rate of wages is practically double that paid in England. The total expenditure on the tramway system has been as near as possible £300,000.

Christchurch, New Zealand.

The city of Christchurch is situated in the South Island of New Zealand, on the River Avon, about five miles from the sea, and is only 16ft. above sea-level. Recently it has enlarged its area by amalgamating with the adjoining suburban boroughs of Sydenham, Linwood, and St Albans. Its population is now 48 737, its area 4,598 acres, its capital rateable value £6,936,149, and its unimproved rateable value £3,095,928.

Electricity Supply.—The Council, about three years ago, expended a considerable sum in the erection of an up-to-date refuse destructor. This was built by Messrs. Meldrum

Digitized by Google

Bros. on the lines of the Beaman and Deas patents. There are two units, or four back-to-back cells fed from the top with combustion chambers, and the heat generated is used for raising steam in a Babcock and Wilcox boiler. Electric generating plant has been provided in connection with this installation, and a considerable portion of the centre of the city is now supplied with light as well as with power. The destructor has been erected at a very short distance from the centre of the city, and though at first there were some complaints of offensive fumes, these appear to have died out. The chimney is 150ft. in height above the level of the ground. The demand for light and power has already increased to such an extent that the Council have been compelled to double their plant, and, as a consequence, it is necessary to burn coal as well as town refuse. Although this plant is still relatively small (two units of 100 kw. each), the revenue is sufficient to pay all working expenses, together with interest and sinking fund and depreciation, and yet to leave a fair profit. The charges made for the supply of electric current for lighting are: under 500 units, 6d. per unit; from 500 to 1,000 units, 4d. per unit; for each unit over 1,000, 3½d. For power and heating 2½d. per unit is charged. It is safe to assume that further extensions will have to be undertaken by the Council at no very distant date. The present arrangement can be but a makeshift at best.

Tramways.—A Tramway Board has been recently created, which, having acquired the old horse and steam tramways, now deals with the whole system within Christchurch and to and within its suburbs. A portion of the new system of electric tramways was opened to traffic on June 5. The work has been carried out by the New Zealand Electrical Construction Company, which commenced operations on Sept. 29, 1904. The amount of their contract was £249,876, but the work is estimated to cost over £300,000, whilst the Board has power to borrow £405,000.

Permanent Way and Equipment.—When completed there will be in all 32 miles and 26 chains of track. The gauge is 4ft. 8½in., and the rails are of the girder type, 92lb. and 95lb. per yard (in 40ft. lengths), while some small quantity for car-sheds and special work are 72lb T-rails. The whole are laid on wooden cross sleepers. The overhead equipment is carried by steel and wooden poles. The trolley wire (63 miles) is of hard-drawn copper with a working strain of 15,000lb. and a breaking strain of 70,000lb. per square inch. The feeder cables—of which there are 22 positive and negative (65 miles in length)—are of insulated copper stranded wire.

Power Station.—The power station has been erected in Falsgrave-street. It is built in brickwork, and has a frontage to that street of 110ft. The value of the site was £2,500, and the contract price for the building was also £2,500. The engine-room and boiler-room are each 46ft. by 40ft., and the coal bunkers occupy a space of 46ft. by 20ft., and will hold a supply of 600 tons. The trucks are hauled from the railway siding by means of an electric winch. Water is supplied from an artesian well 425ft. deep, with a flow of 200 gallons per minute, and runs into a concrete tank capable of containing 8,000 gallons. There are three Babcock and Wilcox water-tube boilers (each capable of evaporating 6,000lb. per hour), with a working pressure of 150lb. per square inch, and these are fitted with Babcock patent automatic chain-grate stokers driven by a small vertical engine. An economiser is also provided, as well as a condenser of the Alberger type, with cooling tower 33ft. high by 22ft. diameter, and with a cooling capacity of 80,000 gallons of water per minute. The fans in connection with this tower are 8ft. diameter, and are electrically driven. The dynamos are driven by Curtis turbo-generators, two of which are installed. One of these is, however, sufficient to meet all ordinary demands, and the other is kept in readiness as a stand-by. These turbines occupy each a floor space of only 8ft. in diameter, and have a normal load capacity of 500 kw., their overload capacity being 750 kw., or 1,000 h.p. each. The shaft has a speed rotation of 30 revolutions per second, and the current is generated at 600 volts. The switchboard is made up of 28 enamelled slate panels, and is 47ft. in length by 7ft. 6in. high. The current for lighting purposes is generated at 220 volts by a 20-kw. dynamo directly coupled to a 30-h.p. high-speed steam-engine. Over the engine-room is a 10-ton travelling crane run on roller bearings.

Car Sheds, etc.—The contract price for this building was £8,882, and the cost of the site was £788. There are three bays, each 106ft. wide by a length of 160ft. The tracks are 10 in number, 140ft long, with inspection pits below. The machine and repair shops adjoin the car-sheds on the western side. The machine shop is 118ft. in length, with overhead travelling crane and jib cranes at each end. There are also provided smiths' shop, armature-room, general store, wagon-room, stable, etc, together with the general offices of the Board.

Rolling-Stock.—There are five different types of cars in use—viz.: (*a*) four-wheel combination, with middle enclosed and two open cross seats at either end (two 25-h.p. motors); (*b*) double-bogie combination, one end enclosed and the other open, with seven cross seats (two 40-h.p. motors); (*c*) four-wheel vestibule cars, entirely enclosed (two 25-h.p. motors); (*d*) double-deck cars (two 40-h.p. motors); (*e*) double-bogie box car, entirely enclosed, with compartment at one end for baggage. The Board has also converted some of the old cars into trailers as an experiment. In addition to the ordinary brakes, the cars are fitted with air-brakes, and at each end are attachments of the cow-catcher type for the prevention of serious accidents. All the cars are fitted with electric heaters, which are placed under the seats.

THE TRANSMISSION OF POWER BY ALTERNATING CURRENTS.

BY ALFRED STILL, M.I.E.E., A.M.I.C.E.

(Continued from page 369.)

Capacity of Transmission Lines.—In the case of a concentric or other underground cable conveying alternating currents, the capacity effects may be very great. A large capacity is generally objectionable in practical working, although, as is well known, the effects of capacity tend to balance those of self-induction, and so bring the power factor nearer to unity. If K is the capacity in microfarads of any system of two conductors, n the frequency, and E

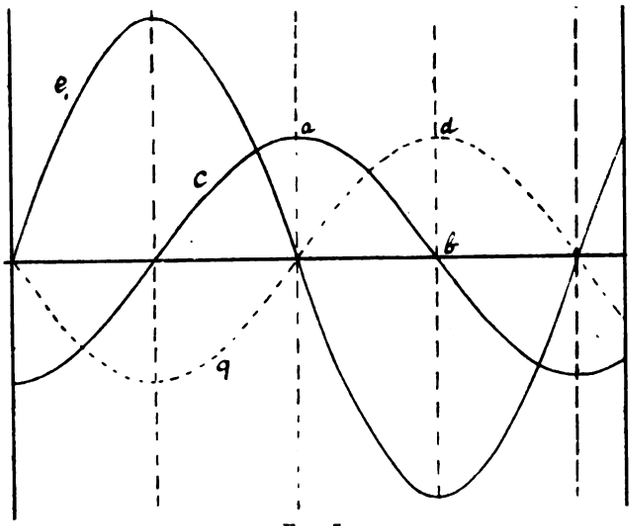

FIG. 5.

the potential difference between the conductors, then the *charging current—i.e.*, the alternating current which will pass between them irrespective of the load at the distant end—will be

$$C = 2\pi n K E \times 10^{-6},$$

on the assumption that the wave form of the E.M.F. is a sine curve. This current is in quadrature with the E.M.F., being 90deg *in advance* of the applied potential difference.

Thus, in Fig. 5, C is the *condenser current*, and the dotted curve *q d* represents the variations in the actual charge of electricity (which must necessarily always reach its maximum value when the current is changing in direction). The *condenser E.M.F.*, or back E.M.F., the direction of which, at every instant, must be such as to tend to *expel* the

Digitized by Google

charge, is represented by the curve e_1. The curve of the applied potential difference has not been drawn, but it will evidently coincide in phase with the curve $q\,d$, being exactly *opposite* in phase to the condenser E M F., which it must balance. It will, therefore, lag behind the current wave by a quarter of a period.

The formula given above enables us to calculate the capacity current without any difficulty, on the assumption of the E.M.F. following the simple harmonic law of variation, provided the capacity, K, can be correctly predetermined, or ascertained by actual measurement; but when we come to consider the various wave forms found in actual practice, it is not possible to calculate the capacity current with any degree of accuracy. The sine curve wave will be found to give the smallest condenser current of any possible wave form, and the most intricate mathematical methods will not enable us to accurately predetermine the capacity effects due to alternating currents of irregular or unsymmetrical wave forms.

The two diagrams (Figs. 6 and 7), reproduced by kind permission of Mr. A. Whalley, of the British Insulated and Helsby Cables, Limited, show the extraordinary distortion of the wave forms due to the introduction of capacity in the circuit of an alternator which does not, under all conditions of load, give a difference of potential at the terminals following the simple harmonic law of variation.

In Fig. 6, V is the pressure and A the current when the alternator is supplying 29·5 amperes at 2,040 volts to a transformer on a nearly non-inductive load, whereas Fig. 7 shows the altered pressure curve and the resulting charging current when the same alternator is supplying a current of 6·04 amperes at 1,980 volts between the two conductors of an insulated cable having a capacity of 4·9 microfarads.

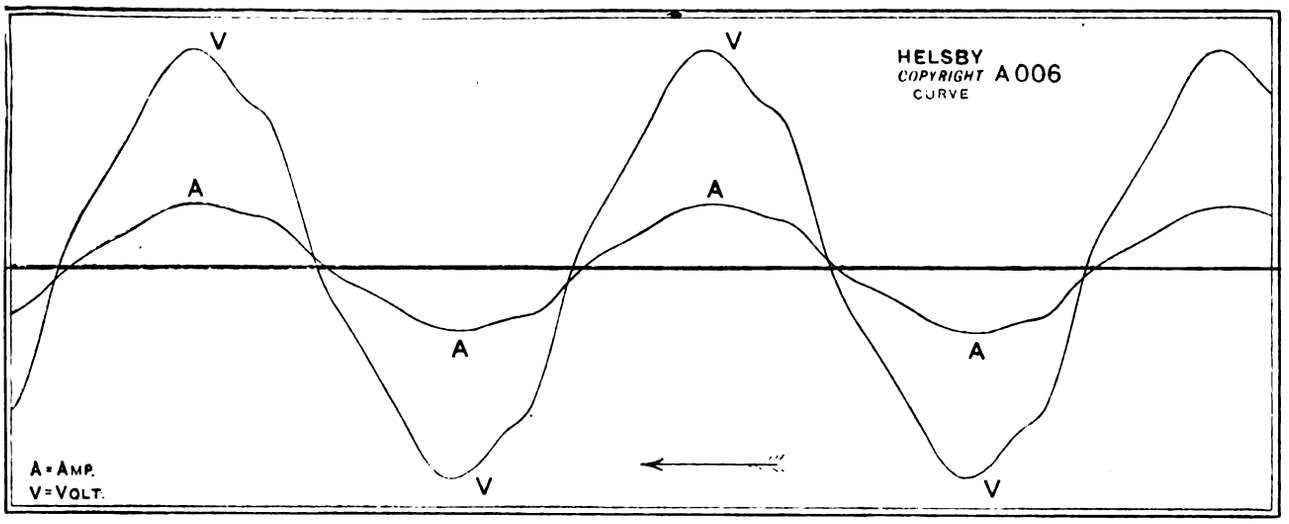

FIG 6.

It is interesting to observe how the smallest ripple in the original curve may become distorted and magnified. The fact that the maximum values of the E.M.F. (and, therefore, of the charge) invariably occur at the instant when the current is changing its direction, should also be noted.

In the case of overhead lines the capacity effects are generally small, and sometimes negligible. The calculation of the capacities between wires, even when symmetrically arranged, appears to offer considerable difficulties to mathematicians, but the formula

$$K = \frac{\cdot 0194}{\log_{10} d/r}$$

applies to the case of a single-phase overhead line.*

Here K = the capacity per mile of circuit in microfarads;
d = the distance between wires;
r = the radius of the wires.

Vector Diagram of Single-Phase Transmission Line taking into account Resistance, Self-Induction, and Capacity.—In Fig. 8 the generator is shown supplying the total current, C, at the initial pressure, E, through the transmission lines to the distant end, where the load is supposed to be partly inductive. The current delivered at the end of the line is C′, and the pressure E′; the coefficient of self-induction of the transmission lines is 2 L, and their resistance 2 r. It will be noticed that the whole of the capacity is shown as being concentrated at the end of the line. This assumption leads to a calculated capacity current somewhat in excess of what would be obtained with the same total capacity distributed along the line, but it simplifies the vector diagram. A closer approximation to actual conditions

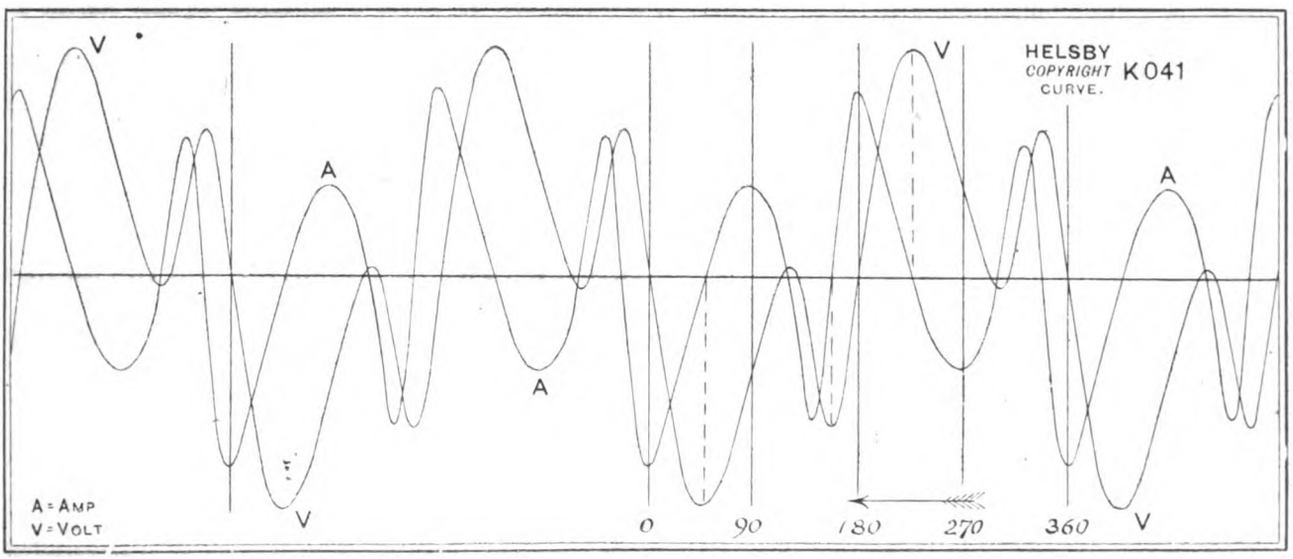

FIG. 7.

* Mr. G. H. Baillie in the *Electrician*, Aug. 8, 1902.

Digitized by Google

would be obtained by supposing the capacity to be concentrated at the centre of the line (or, perhaps, rather near the receiving than the transmitting end); or if still greater accuracy be required, no difficulty need be experienced in drawing the diagram on the supposition that the capacity is due to two or more smaller condensers connected between the lines at different points. But it must be remembered that it is not possible to calculate the capacity current on a long transmission line with any great degree of accuracy, because it will depend largely upon the E.M.F., wave form, which, even if known under certain specified conditions, will generally vary considerably with alterations in the load. The capacity of a system of overhead conductors will also depend somewhat upon the state of the atmosphere.

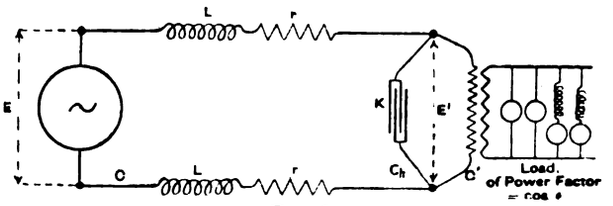

FIG. 8.

Assuming, then, for the sake of greater simplicity of construction that the total capacity, K, of the line is concentrated at the distant end, we may proceed to draw the vector diagram (Fig. 9). Here O E′ and O C′ represent respectively the potential difference and the current at the distant end of the line, the two vectors being drawn with an angle θ between them, such that cos θ is equal to the assumed power factor of the load. Referring to Fig. 8, it will be seen that a condenser of capacity K is supposed to connect the wires at the distant end; the impressed volts at condenser terminals are therefore E′, and the vector for the condenser current (equal to $2\pi n$ K E′, on the assumption of the sine curve wave form) must be drawn 90deg. in advance of O E′. It is represented by O C_k in Fig. 9.

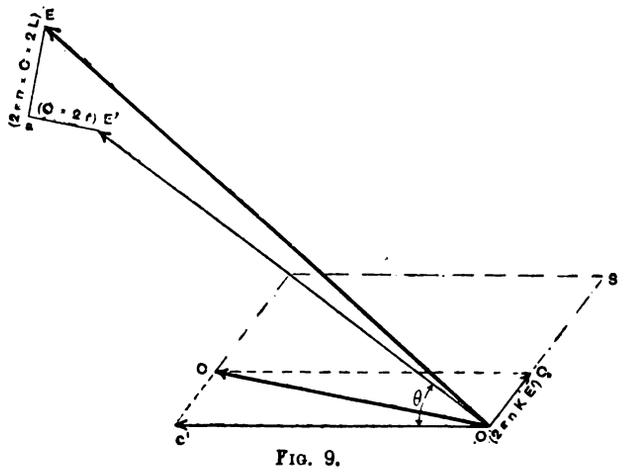

FIG. 9.

The total current supplied to the line at the generator end will be O C, obtained by compounding O C′ and O C_k. With regard to the E.M.F. at generator end, this is the resultant of three components—namely: O E′, the pressure available at receiving end; E′ a (drawn parallel to O C and equal to C × 2 r), to represent the drop due to resistance; and a E (drawn at right angles to O C and equal to $2\pi n$ × C × 2 L), to represent the pressure required to balance the E.M.F. of self-induction. This gives us O E as the necessary pressure at generating end.

The conclusions to be drawn from this diagram (which takes both self-induction and capacity into account) are as follows: (1) On an inductive load the current, C, put into the line at the generating end may be *less* than the current, C′, at receiving end. (2) The total current, C (under the condition of a partly inductive load), comes more and more nearly in phase with the E.M.F. as the capacity current increases up to a certain limit, depending upon the power factor of the load. Thus, if the capacity current were equal to O S instead of O C_k, the total current—as indicated by the chain dotted lines in Fig. 9—would be in phase with E′. This illustrates the effect of capacity supplying the magnetising current of the inductive apparatus constituting the load, and so improving the power factor. (3) The effect of capacity (always on the assumption of a low power factor), by reducing the current in the line, is also to diminish the $C^2 r$ losses or to permit of a smaller section of conductor being used.

It must not be forgotten that these conclusions are derived from a diagram which represents the conditions under full load, or when the total current is large in comparison with the charging current; and, in considering the question of power losses, we must not overlook the fact that, *at light loads*, the charging current may be the cause of *increased* $C^2 r$ losses. In other words, on a low *load factor* (whatever may be the power factor, but more especially when the power factor is high), a large capacity current may not be an unmixed blessing, even when viewed solely from the point of view of its effect on the line losses. As a matter of fact, the charging current on overhead lines is generally small. Let us take as an example the same data as served us to illustrate the effects of self-induction—that is to say:

The pressure E′ = 20,000 volts.
The frequency n = 25.
The length of the line = 50 miles.
The diameter of conductors = ·36in.
Their distance apart = 3ft.

Using the formula given above for the capacity of an overhead line, we have

$$\text{Capacity in microfarads per mile} = \frac{\cdot 0194}{\log 36/\cdot 18} = \cdot 00843,$$

which gives us for the total capacity,

$$K = 50 \times \cdot 00843 = \cdot 4215 \text{ microfarad.}$$

The capacity current will be

$$C_k = 2\pi \times 25 \times \cdot 4215 \times 20{,}000 \times 10^{-6} = 1 \cdot 3 \text{ amperes,}$$

which is a very small percentage of the total current (assumed to be about 50 amperes). At the same time, we have only to suppose an increase in the length of line from 50 to 200 miles, with a correspondingly higher pressure of, say, 50,000 volts, and imagine the frequency to be 50 instead of 25, in order to obtain a calculated capacity current of 26 amperes, which is by no means negligible.

It will be understood that where insulated cables are used (only possible for lower pressures and shorter distances), the capacity current may be from 20 to 30 times as great as in the case of an equivalent overhead transmission, and, moreover, the dielectric losses may become important.

(To be continued.)

ELECTRIC POWER DISTRIBUTION FOR THE RAND.*

BY ROBERT HAMMOND, M.I.C.E.

The idea of laying down central power stations for the purpose of affording a cheap supply of electric energy over extended areas is one that is being adopted in all parts of the world. The earlier works of this description, like those at Niagara Falls, were laid down for the purpose of utilising water power only available at one central spot. Latterly power distribution schemes have been devised in England in places where no water power is available, but where economy in the cost of generation from aggregation of output is relied upon. So markedly is this economy attained that one of the most progressive of our English railway companies, the North-Eastern, has found it actually more economical to draw its supplies of electrical energy for the working of 37 miles of railway from a central power distribution company than to erect its own generating works.

In the present session of the British Parliament powers were sought by a company to carry out a huge power distribution scheme for London in spite of the fact that there are already in existence in the Metropolis 61 electric generating works operating under statutory powers, with a

* Paper read before the Engineering Section of the British Association at Johannesburg, Aug. 30.

Digitized by Google

capacity of over 200,000 kw., in which some £16,000,000 have already been invested, and with an annual output of about 160,000,000 units. The argument advanced by the promoters was that by means of entirely new works, equipped with highly efficient generating plants, each of 10,000 kw. capacity, laid down on a site where river water is ample in quantity and available for condensing, and where coal could be delivered alongside, it would be possible to sell electric energy in bulk to the present distributors at a price so low that it would pay them to scrap their existing works. They had, indeed, already entered into provisional contracts to supply at £3 per kilowatt per annum of the consumer's maximum demand plus ·33d. per unit for all electric energy actually used. Presuming an average use of the maximum demand for eight hours per day, excluding Sundays and public holidays, say, 307 working days per annum, we have:

Cost of 1 kw. per Annum

Fixed charge	£3	0	0
307 days and 8 hours = 2,456 units at ·33d. per unit	3	7	6
	£6	7	6

equivalent to an all-round charge of ·62d. per unit. If the average use during the 307 days was 12 hours per day, the payment by the consumer on the above basis would be ·477d. per unit.

During a visit paid by the writer to Johannesburg during the early part of this year he was struck by the fact that in such a dense industrial area as that included in the Witwatersrand, "power distribution" undertakings of magnitude were not in operation. Within a radius of about 25 miles of Johannesburg, calculating only the main shafts in active operation in producing and developing mines, there are some 150 shafts into the gold-bearing banket, and the number increases annually, the workings varying from "surface" to deep level 3,000ft. below the surface. The total number of tons (2,000lb.) mined and hoisted in April of this year was 1,074,464, and after sorting 898,871 tons were milled in 6,532 mills. It is expected that the average for the current year will be rather over than under these figures, startling as they are; and it is certain that in the future operations will be conducted on even a larger scale than at the present time.

The object of this paper is to raise two questions before the Engineering Section of the British Association: firstly, whether the working of the mines could not be cheapened by the greatly-extended application of electric power; and, secondly, whether such electric power could be more economically produced by each mine or group of mines laying down its own plant, or by means of centralisation of generation in works serving a number of mines.

With regard to the general question of the use of electrical energy in mines it may be noted that in the United Kingdom there has been, as usual, great hesitation in adopting new methods and in introducing electricity into mines. Fear of the attendant danger was for a time the great stumbling-block. In 1902, however, a strong committee was appointed by the Home Office with instructions "to inquire into the use of electricity in coal and metalliferous mines and the dangers attending it, etc." That committee, after an exhaustive inquiry, in the course of which evidence was taken from 56 expert witnesses, issued its report on Jan. 9, 1904, and pronounced very strongly in favour of the use of electricity in mines under proper restrictions and precautions. The result has been a great extension of the use of electricity in mines in the United Kingdom. To name one instance, the Powell-Duffryn Steam Colliery Company has eight pits in one valley, and in the present system have installed 5,000 h p. of motors distributed over different collieries. When all the motors are at work some 80 steam-engines, together with boilers for them, will be thrown out of use. At the present time the chief application of electricity is for hauling the trams from the face to the foot of the shaft, and at the same time electricity is being adopted throughout for pumping, ventilating, shunting, screening, lighting, and the working of all colliery machinery, such as workshops, mills, mortar mills, etc. Three electrical winding engines are also being put in of small horse-power for raising and lowering men. Now that the plant has been started, and it has been found that such satisfactory results are obtained, it has already been decided to adopt electrical winding, and the plans for installing an electrical winding engine are almost completed. This work will be put in hand during the next few months.

Turning to the Rand, the question to be first decided is whether a cheapening of the working of the mines would be obtained by a similar extended application of electric power. From the communications of Mr. J. A. Vaughan, chief inspector of machinery to the Government mining engineer, Johannesburg, it appears that there are already in use in the Rand mines electric motors of a total capacity of about 20,000 h p, and the number is being rapidly augmented. Electric energy is at present used for underground and surface pumping, for workshop driving, and in the cyanide works, for pumping the water, the solution, and the slimes. In some mines it is used for crushers, for haulage, for the conveyor belts, and in the mills. From a perusal of the *Proceedings* of the South African Association of Engineers it appears, however, that many of the leading engineers of the Rand are in favour of largely extending its use. Among other important papers read before that association may be specially mentioned: Oct. 29, 1902, Spengel, on "Electric Winding Engines"; Sept. 28, 1904, Pearce, on "Electric Equipment, etc."; Feb. 22, 1905, Wilms, on "Electric Driving of Stamp Batteries."

Electric winding has already been adopted in some of the leading mines in Westphalia and in Belgium, steam hoisting plants formerly in use having been scrapped. The writer recently inspected the St. Nicolas pit of the Esperance et Bonne Fortune Collieries Montegnee, near Liége, where electric winding is in successful operation. Some particulars of this installation may prove of interest to engineers of the Rand. It is designed to draw about 500 tons from a depth of 2,625ft. in eight hours. The loads are four tubs holding 1,100lb. of coal. Each tub weighs 550lb, and the cage weighs 1¾ tons. The diameter of the pulley is 3m. (9ft. 10⅛in.). The haulage speed is about 33ft. per second when the motor makes 64 r.p m. The writer not only advocates the adoption of electric winding, but he fully believes that almost every operation at present performed by steam power could more economically be effected electrically if the power were generated at a central power station supplying the whole of the mines. He has in mind air compressing, haulage and pumping (both underground and on the bank), ventilation, stamp mills, crushing, sorting tables, tailing wheels, and tramways.

It will be noticed that the writer places air compressing at the top of the list. The almost universal practice on the Rand is to work drills by means of compressed air supplied from works on the surface. This method is most uneconomical, as, owing to the inevitable leakage and friction losses, the distribution of compressed air through a long series of pipes results in a serious loss of power, variously estimated at from 50 to 75 per cent. of the power produced on the bank. This should give place to a system by which electrical energy is utilised underground to work compressors placed in ventilated positions within 200ft. or 300ft. from the workings. Under such a system over 75 per cent. of the energy delivered to the electric line would be available at the tool, say: efficiency of distribution line, 95 per cent.; motor efficiency, 95 per cent.; mechanical efficiency of compression, 92 per cent.; volumetric efficiency of compression, 94 per cent.—say, 95 per cent. of 95 per cent., of 92 per cent., of 94 per cent. equals 78·048 per cent. Some have objected to the abolition of the surface compressed-air plant on the ground that the exhaust air is an important element in the ventilation of the mine.

It does not seem to the writer probable that the ventilation of a mine can be dependent to any appreciable degree on the exhaust air from the percussive machines on the face. Surely the whole system of ventilation is one to be dealt with on lines which involve the motion of huge volumes of air at very low pressure, and the percentage effect of the discharged air from the percussive machines would seem to be too trivial to be worth notice. The only case in which the exhaust air from a pneumatic tool may have an appreciable effect upon the ventilation is when men are working on the face on a dead heading. The use of portable compressors would not, however, effect this ventilation in any way, as the compressor naturally cannot be

Digitized by Google

placed close up to the face but at a short distance from it in a recess made at the side of one of the main ways. This spot would be fully ventilated by the main ventilating system. It is immaterial to the men working at the face whether the air comes through great lengths of pipes from the surface or through 200ft. or 300ft. of pipe from a compressor in a ventilated position.

With regard to the remaining operations, in one important respect the mines on the Rand work under conditions very favourable to the use of electricity. Pumping operations are generally continuous. For 24 hours per day and seven days per week mining operations are continuous; for 24 hours a day and six days a week milling operations are continuous, in most of the mines (some not milling on Sundays) for 24 hours and seven days a week. Here we have the ideal condition of practically continuous working. Throughout Europe and the United States, in the case of industries so operating, it has proved advantageous to abandon the use of steam in favour of electricity.

Having agreed that the use of electrical energy on the Rand has an enormous field, the question arises as to whether it could be more cheaply obtained from one central station or from separate works supplying one group of mines. Obviously the nearer the generators are to the work to be performed the less the capital outlay on distributing cables, and consequently the less dead interest thereon, the less the cost of upkeep and the less energy lost in distribution. In every "power distribution" scheme the main point to be considered is whether the advantages of centralisation do not outweigh the disadvantages arising from losses in transmission and distribution. To take an extreme case, there would be no engineering difficulties in supplying electrical energy to all the mines on the Rand from a central power-house utilising the Victoria Falls on the Zambesi; but, even disregarding the cost of the enormous works necessary for utilising the water power, the annual charges on the cost of the erection of the electric lines would far outweigh the annual outlay on coal used in works laid down on the Rand.

In order to fully appreciate the problem it is necessary to carefully note how the costs of generation of electrical energy are made up. They divide themselves almost equally into (I.) capital charges; (II.) working expenses.

I. *Capital Charges.*—(1) Interest upon the capital invested; (2) depreciation fund to provide for (*a*) the wearing out of the plant, (*b*) its antiquation.

II. *Working Expenses.*—(1) Coal, gas, oil, or water used as the motive power; (2) (in the case of steam-engines being employed) water (*a*) for boiler feed, (*b*) for condensing; (3) oil, waste, and stores; (4) wages; (5) repairs and maintenance; (6) general expenses, management, etc.

A careful study of each item in turn will lead to the conclusion that aggregation of output tends to economy in every one of them.

I. *Capital Charges.*—By aggregation of output and the resultant diversity factor less plant is required, and, therefore, a lower sum has to be provided annually for interest and for depreciation. By aggregation of output, plants of larger size can be used and the capital expenditure thereon minimised.

II. *Working Expenses.*—Taking each item in turn and confining our attention to steam-driven plants: (1) Coal—Plants of the largest size, which can only be used in works having an enormous output, use less coal per brake horse-power than those of smaller size. Before a recent Parliamentary Committee it was stated that in the case of a particular type of steam generators that the 5,000-kw. sets used 25 per cent. less steam and the 10,000-kw. sets 33 per cent. less steam than the 1,000-kw. sets. (2) Water—(*a*) For the boiler feed. The less steam used in the generators the less will be the water evaporated in the boilers. (*b*) For condensing. The less steam passing through the generators the less water required for the condensing. (3) Oil, waste, and stores—By means of the saving devices possible in plants of large size there would be an economy possible under this head. (4) Wages—There would certainly be an economy here because the same number of men required to operate, say, six plants of 1,000 kw., could as easily work the same number of plants of 10 times the size. (5) Repairs and maintenance—Engineers are aware that the percentage on value disbursed on plants of large size is less than that on plants of smaller size. (6) General expenses, management, etc.—Here, again, it is a truism that large businesses can be managed more economically proportionately than small ones. Possibly, however, there is no need to dwell further on the now almost universally conceded proposition that aggregation of output leads to great economy in production.

In order to apply our general principles to the supply on the Rand, it is necesary, to estimate the total amount of power, electrical and steam, used at the present time. This may be approximated from the amount of coal consumed annually. In the exhaustive report on the working of the Central South African Railways for the year ended Dec. 31, 1904, presented to the chairman and members of the Railway Committee on March 25 last by Mr. T. R. Price, the general manager of the railways, it is stated that "no less than 1,864,926 tons . . . . . consists of coal traffic, chiefly, of course, though not exclusively, for the gold mines." Supposing 1,250,000 tons out of 1,864,926 tons are taken by the gold mines on the Rand, how many horse-power hours does this represent? The coal varies in quality from 12,000 to 8,000 British thermal units per pound. But even so, an average of 6lb. of coal per brake horse-power hour is probably an outside figure, though with the view of keeping the estimate well within bounds the writer adopts it thus:

$$\frac{1{,}250{,}000\ (\text{tons}) \times 2{,}000\ (\text{lb.})}{6\text{lb.}}$$

equals 416,666,666 horse-power hours, or to deal with round figures, say 400,000,000 horse-power hours per annum, equivalent to an average output throughout the year of over 45,000 h.p, working day and night without intermission.

Of course, many of the operations are not continuous, so that the average of over 45,000 h.p. will constantly be exceeded, and at times more than doubled. To arrive at the exact amount of horse-power in use on the Rand is difficult, if not impossible, but a fair approximation may be made by a study of the data kindly supplied by some of the leading mines. In the case of 16 mines, which raised 316,371 tons of ore in the month of April last, 35,894 h.p. was in use. The total quantity used by all the mines during the same period was 1,074,464 tons, and if dealing with 316,371 tons of ore necessitates a maximum of 35,894 h.p., the 1,074,464 tons would, as a mere matter of proportion, require 121,903 h.p. Whatever, however, may be the total capacity of the plant, the broad fact stands out that a conservative estimate places the total requirements of the Rand mines at the enormous figure of 400,000,000 horse-power-hours, or, say, 300,000,000 units (kilowatt-hours) per annum.

In order to arrive at the total capacity of a central power-house to deal with this output, it is necessary to consider the load and diversity factors which would be obtained. The success of a central power station depends entirely upon its ability to afford a supply of energy at very low rates. The extent to which aggregation of output leads to economy in working costs practically turns upon the excellence of the load and diversity factors which would result from the supply to a large number of consumers. Under these conditions the writer hopes that he may be pardoned for going into the question of load and diversity factors in some detail. The term "load factor" is the name given to the ratio of the actual output of any works during a given period to what that output would have been had the works been operating at their maximum rate throughout that period. A moment's consideration will show that this ratio must have an important bearing upon working costs, not only in an electricity works, but in any industrial undertaking. If the load factor of any industrial concern be high, or, in other words, if the output of the works be maintained at a steady rate varying only slightly from the maximum obtained at any one time, it is obvious that the cost of the output will be lower than if the same works with the same output were working night and day at high pressure one week and half time the next.

THE DISTRIBUTION OF POWER.*

BY PROF. AYRTON, F.R.S.

(*Concluded from page 413.*)

Now, this is the very opposite of the effect we previously noticed, for in that case it was the alternating pressure that failed to send the current into the transmission system. Surely, then, the one effect is a correction of the other. That is so, and I will give you a practical illustration. I have here two transmission lines, the one with its going and return conductors placed far apart so as to exaggerate the first effect; the other with its going and return conductors near together to exaggerate the second effect; indeed, as I am employing for this experiment only a pressure of 100 volts, there is no risk of brush discharge, and so I have put the wires extremely near together on the second transmission line. The alternating current produced by the dynamo divides itself between the two transmission lines, and the two branch currents are about equal. But, as you may see by means of the oscillograph—an instrument developed in my laboratories by Mr. Duddell, one of my students, for giving us a picture of the current and pressure waves in each of the two circuits—there is a great difference between the waves in the two circuits. In the transmission line with the wires far apart, the reversals of the alternating current occur after the reversals of applied pressure, the crests of the current wave lag behind the crests of the pressure wave, whereas in the case of the transmission line, with the wires very near together, the exact opposite occurs—viz, the crests of the current wave are in advance of the crests of the pressure wave.

Now, in the circuit coming from the dynamo, both current waves exist together, and as the crests of the one wave co-exist with the troughs of the other, there is interference, and the result is practically no current at all. So here we have the rather surprising result of practically no current in a main circuit, and yet a considerable current in each of the branch circuits into which the main circuit divides. This may perhaps be regarded as a beneficial result, and should be added to the score of alternating current. But just as a very small alternating current in the main circuit can be split up into two large currents in the branch circuits, a small alternating pressure can be split up into two large alternating pressures, and in that case the result must be scored against the use of alternating current. In this experiment I use also two circuits, one with the conductors very far apart, and the other with them very near together; but, instead of employing these circuits as two *branch* transmission lines, I put them end on so that they constitute *successive* portions of the same transmission line. An alternating pressure of only 69 volts is provided by the dynamo, and applied to the whole arrangement, and yet you observe that between the going and return conductors in that part of the circuit in which they are far apart, as well as in that part in which they are near together, a pressure exists of 2,400 volts, which is 35 times as great as the entire pressure supplied by the dynamo to the mains. This result with alternating electric pressures is not unlike that obtained with mechanical forces when a small force is resolved into two very large ones, with each of which it makes nearly a right angle. Much damage has been done to electric cables used for the distribution of power by these unexpected high pressures produced by resonance in alternate-current circuits. A cable may have been tested at twice or thrice the working pressure and passed as satisfactory. But if there is a liability of a pressure being applied which, as you see, may in somewhat extreme cases be 20 or 30 times the working pressure, what avails it there being a factor of safety of 2 or 3—disaster must follow.

Now, with direct current for long-distance transmission, there is no question about the electric pressure at the top and bottom of a wave being much greater than the mean pressure, no question about self-induction reducing the current—no objection, therefore, to putting the conductors as far apart as the risk of brush discharge may necessitate—no question about capacity current, no resonance troubles, etc. I wonder whether any of you are thinking, Well, perhaps, there may be something in this heresy after all. No? Oh! then you are thinking, if the arguments were sound, the direct-current system would have been already employed for long-distance transmission. Well, but it has! Power up to 3,000 horse has been transmitted with direct current, at 14,000 volts, from Combe Garot to Le Locle and La Chaud de Fonds, round a circuit 32 miles long, 4 600 h p. has been transmitted with direct current at 23,000 volts, 35 miles from St. Maurice to Lausanne, and a transmission system for 6,000 h.p. at 60,000 volts, over 114 miles from Moutiers to Lyons, is in course of construction.

Another advantage that is possessed by all these examples of direct-current transmission carried out by M. Thury is that it is the current that is kept constant, and the electric pressure that is automatically raised, when the demand for power is increased, whereas with the ordinary alternate-current system it is the pressure at the lamp end that they aim at keeping constant, and the current that varies automatically with the demand for power. Now, it is far more easy to maintain the constancy of the current flowing round a long circuit than to prevent the bobbing up and down of the electric pressure at the distant end of a long transmission line, and that irritating dancing of the lights, which Johannesburg is so familiar with, would be particularly difficult to avoid if the transmission line were long and the electric pressures at its two ends differed by some thousands of volts. Constant current has also its well-known disadvantages, but these would not come into play if the constant current were not taken into houses, mines, etc, but used to drive motor-generators in substations, the dynamo portion of the motor-generator being of any type desired.

The pioneering development that American boldness, enterprise, initiative, and originality have brought about in the electric distribution of power, combined with the extraordinary commercial success that it has won on both sides of the Atlantic, have made people ask, "Is such an industrial revolution in store for South Africa?" At first sight one is inclined to answer, "No!" This country is dotted with coalfields—coalfields blacken the map, and the produce of some of them is reported to be nearly equal to the best Welsh coal in quality. A humorous English paper said that I was going to give this lecture standing on a coal wagon, to indicate how superior, as a carrier of energy, was a coal cart to a current. When, on the one hand, one hears that good coal is brought from Witbank and delivered to the mines on the Rand at 13s. a ton, and that even this price will be lowered on the completion of the new railway from Witbank to Brakpan, one feels that long-distance electric distribution has not much chance; indeed, a proposal to burn slack coal at Vereeniging, only 33 miles from Johannesburg, and electrically distribute the power on the Rand, fell through. On the other hand, when one finds that at the Wankei coalfields themselves large coal costs 15s. a ton *at the pit's mouth*, and that Salisbury pays 36s. 5d, Umtali 43s. 6d., and Kimberley 67s. per ton, one feels that electric distribution in this country possesses possibilities. South Wales has many coal mines—cheap slack coal lies heaped at the pit's mouth. Let me put this question to you: "If an electric supply distributing company were to start in South Wales to obtain their electric energy, *not* from waterfalls, mark you, but from coal brought to their generating stations from coal mines, would you anticipate, I ask, that such a company would obtain customers for their electric energy at coal mines themselves?" "No, emphatically no," you would reply, for that would be taking coals to Newcastle with a vengeance. And yet, what does that map tell us? Why, that within four years since that South Wales company was merely applying to Parliament for an Act to enable them to establish a distribution of power system, 14 of the largest colliery companies and 30 of the mines are taking power at about ½d. a horse for an hour, the demand three months ago having reached 13 000 h p., and rapidly increasing. That the North-Eastern Railway, and such a large number of manufactories along the Tyne, should, as seen from that other diagram, take power from the Tyneside Electric Power Supply Company—which also

* Lecture delivered on Aug. 29 at the meeting of the British Association at Johannesburg.

Digitized by Google

has been but four years in existence—was perhaps to be expected, but that coal mines should obtain power by the burning of the product of distant collieries resembles at first sight the method of earning a living attributed to a certain village—viz, by taking in one another's washing.

But this result is but an example of the sub-division of labour. At a coal mine, getting coal, and at a gold mine, getting gold, is the business; and at both, especially in the early days of sinking the mine, it should pay better to buy electric energy from an outside source than to generate the current on the spot. Niagara sends 24,000 h.p. to Buffalo, 30 miles away, and sells at 0·7d. per horse-power hour to an eight-hour user there—a price which is *not* cheaper than the total cost of generating a horse-power hour at Buffalo with a *large* steam-engine. But tapping electric wires to obtain any amount of power that may be needed, and just at the time that it is required, is far more convenient than erecting steam-engines and getting up steam, and certainly cheaper in the early days of sinking a mine. It has been objected that the total steam-power curve of all the gold mines on the Rand show the same sort of falling off during the hours 4 to 7 a.m. and 5 to 8 p.m., and, therefore, that, apart from using larger and more economical engines, and from diminishing the cost of superintendence for the energy sent out, there would be no saving by supplying many mines with electric power from a common generating station. But if there be a railway in the neighbourhood, largely used by workmen, the slack hours on the mines will be the busy hours on the railway. Hence, if that railway be run electrically from the same generating station, the load curve will be flattened and much improved. On the Rand, however, there is an indisposition apparently to utilise distribution of power on a large scale. The labour conditions in this country are certainly peculiar. My friend, Mr. Denny, in his book on "Deep-Level Mines of the Rand and their Future Development," expresses this opinion—and there is no man whose opinions on such matters I value more highly—"It has, however, been fairly conclusively proved that in average conditions hand labour is both speedier and cheaper than machine drilling." But when one watches this hand labour, one thinks of this picture rather than that. Contrary to American and Australian experience, it may be true that in this country white men and machinery may be dearer and slower than black machinery and man rolled into one. But it makes one uncomfortable, even unhappy, to think it possible, for it means that the muscular machine is more valuable than the inventor's brain.

Another objection felt by mine owners here to investing much capital in machinery is the somewhat uncertain character of their business, and a third against a mine depending for a supply of power on an electric current coming from a distance is the climatic conditions. South Africa has various unique big things, but it has not a monopoly of big atmospheric disturbances, and these disturbances do not prevent electrical distribution of power schemes being pushed forward by leaps and bounds in the other three quarters of the world—the list given in Table II. is merely a selection from some of those using the highest working voltages. During my short stay in this country I have been giving this matter much consideration. Without stopping this evening to discuss the subject in detail, I may mention that, after the admirable work of Mr. Wilms, Mr. Spengel, Mr. Heather, and others here on the improvement of lightning arresters for electric transmission lines, I think I also see my way to putting a nail into the coffin of these bugbear lightning troubles.

But, while advocating electric transmission of power, I should not start by constructing a transmission line from the Victoria Falls to Johannesburg. And I say that not because I am of opinion that it could not be made to work, nor that, if direct current were used, it could not be relied on to give as satisfactory results as, or even better results, than some shorter existing ones on the alternate-current system, but because it does not appear to me that along the route there is at present sufficient demand for power to justify as large an expenditure of capital as would be compatible with a transmission line 586 miles long as the crow flies, and which would be no less than 745 miles long if made along a railway through Pietersburg and Gwanda, should that missing stretch of railway between these two places ever be constructed. Those who hold the opposite view will doubtless urge that when the Cataract Construction Company of Niagara acquired in 1890 the right to use 100,000 h.p., and a further right to subsequently use another 100,000 h.p., it required an extraordinary belief in the future of electrical engineering to expect that 200,000 h.p. could ever be distributed at a price that could compete with large local steam-engines, and they will ask, Did not even Mr. George Westinghouse advise Mr. Stetson, the first vice-president of the Cataract Construction Company, in 1890, that it would only be by compressed air that power could be commercially transmitted from Niagara to Buffalo? And now what is the state of things? Power-house No. 1 with 10 5,000-h.p. dynamos has been working for some time, power-house No. 2 with 11 more 5,000-h.p. dynamos was completed last year. Hence 105,000 h.p. can be developed, and of this 75,000 h.p. is regularly distributed. Further, the Canadian Niagara Power Company are constructing an electric station of an ultimate capacity of 110,000 h.p., the Ontario Power Company an electric station a little lower down of 200,000 h.p., and the Toronto Power Company one a little higher up of 100,000 h.p., all these three being on the Canadian side. Also the Electric and Hydraulic Company, who in 1881 started with a station on the American side to supply only 1,500 e.h.p., have in hand a third station which will bring their plant capacity up to 135,500 e.h.p. Consequently the total electrical horse-power that could be sent out from these various Niagara power-houses when completed will approach 700,000 h.p., and represents about 30 per cent. of the water going over the Falls at the time of *minimum* flow. But taking into account the further fact that water is already abstracted to feed the Welland Power Canal and the Chicago Drainage Canal, and that other canals are projected, Mr. A. D. Adams has estimated that about 41 per cent. of the minimum flow of Niagara will cease to pass over the Falls. In fact, *the water that will cease to pass over the Niagara Falls will be nearly five times as large as the total amount passing over the Victoria Falls to day.*

The "Thunder of the Waters," the "Cataract of Fearful Height," in America, which have inspired us and our ancestors with reverential awe, may appeal to our descendants as only a vast electric generating station. Very gratifying to us as engineers—extremely distressful to us as lovers of the beautiful. Now, what has caused this vast development in the distribution of power, what is the secret of this extraordinary success? It is that in the immediate neighbourhood of the Falls there have grown up works which take some 60,000 h.p., works which not only want cheap power, but power in an electric form for electro-chemical processes, and need it an undiminished amount, day and night, week-day and Sunday. The Carborundum Company, which manufactures emery's rival grinding material, furnishes an absolutely steady load of 5,000 e.h.p., the Union Carbide Company 15,000, and so on, loads which, from their magnitude and their absolute steadiness, make the electric light engineer's mouth water.

Now what is the prospect of such a steady load growing up locally within, say, three miles of your falls? Even on the spot it is difficult to obtain trustworthy information; by some it is said that one condition of the contract for the construction of the railway, which is being pushed forward to the copper, lead, and zinc fields at Broken Hill, 400 miles to the north-east, is that 100,000 tons of the ore must be sent to Beira yearly for 10 years. If true, then that ore will not be available for reduction at the falls. There is a convenient spot for a power station near the water at the end of the second gorge—all the Niagara power stations are on the top of the falls with the exception of that of the Ontario Power Company—and it is the latter method of construction that would be the most suitable to follow at a Victoria power station. But jealously guard the beauty of your falls. The protection of the grandeur of their American sister was the underlying idea of Thomas Evershed's hydraulic power scheme of 1886. How little has that object been kept sight of? Niagara *was* glorious nature, to-day it is power; Victoria is poetry.

EDDY-CURRENT LOSSES IN ARMATURE CONDUCTORS.

Some useful experiments on this subject have recently been carried out by Messrs. B. Loewenherz and A. Van der Hoop, and described in the *Elektrotechnische Zeitschrift*, from which we take the following details. The tests were made on a special iron core shaped like a shell transformer, and shown in Figs. 1, 2, and 3. The dimensions are given in millimetres. The central part of this core represents one complete slot and two half slots of a slotted armature, and into these slots copper bars of various types can be inserted, whilst by passing an alternating current round the magnetising coils, the teeth and slots can be magnetised to any required extent, and corresponding eddy-current losses occur in the copper bars, much as in the case of a rotating slotted armature. The eddy-current losses were measured calorimetrically, the method being based on the fact that the heat developed in a body is partly employed in raising the temperature of the body and partly dissipated to surrounding objects. The first part is given by the product of temperature rise and water equivalent of the body. The second part is less easily arrived at, but preliminary experiments proved that for the case in question, where the copper bar in a slot is quite enclosed from the air and practically surrounded by iron, the total dissipated energy was proportional to the temperature difference between the copper and any given point on the surrounding walls. The writers show that the connection

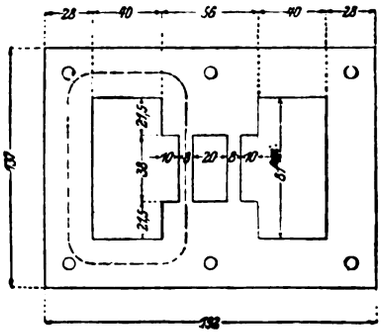

FIG. 1.

between eddy-current losses and temperature may be stated as

$$Q = K \frac{\int_{t_1}^{t_2} \Delta T \, . \, dt}{t_2 - t_1} + Cg. \frac{T_2 - T_1}{t_2 - t_1},$$

or, allowing for change of ohmic resistance with temperature,

$$Q_0 = \left\{ K \, . \, \frac{\int_{t_1}^{t_2} \Delta T \, . \, dt}{t_2 - t_1} + Cg. \frac{T_2 - T_1}{t_2 - t_1} \right\} \times \frac{A + T_0 + \frac{\int_{t_1}^{t_2} (T - T_0) \, dt}{t_2 - t_1}}{A + T_0}$$

where Q = eddy-current loss in unit time;

Q_0 = eddy-current loss in unit time reduced to a normal temperature, T_0;

K = a constant determined from a large number of cooling tests by means of the expression

$$K = Cg. \frac{T_2 - T_1}{\int_{t_1}^{t_2} \Delta T \, . \, dt}$$

t_1 and t_2 = the times at the beginning and end of the reading;

ΔT = temperature difference between the copper conductor and the surrounding iron;

$Cg.$ = the water equivalent (as regards heat absorption) of the copper conductor;

T_1 and T_2 = the temperatures of the copper at times t_1 and t_2 respectively;

A = a temperature coefficient depending only on the material of the conductor.

The temperatures were measured by fine-wire platinum resistance thermometers, and the maximum values of the flux densities both in the teeth and in the slots were obtained by winding exploring coils at the required points and determining the curves of the induced voltages.

A series of 20-minute tests, with five or six sets of temperature measurements in each, was made with seven

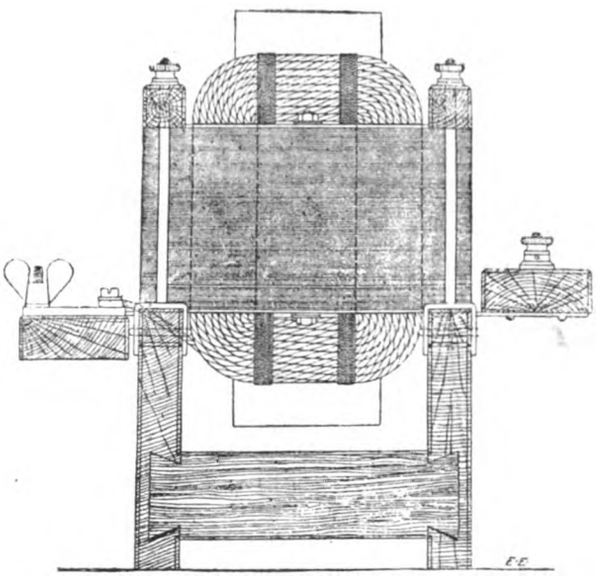

FIG. 2.

different excitations at 50 ~, and from the curves connecting temperature rise of copper and of iron with time, so obtained, together with the corresponding cooling curves, the numerical values of the various constants in the above equations were obtained and the eddy-current losses per one cubic centimetre of copper calculated. This whole series of tests was repeated with the six different types of copper filling shown in Fig. 4.

The results arrived at in this way are given in Figs. 5 and 6. Fig. 5 shows the connection between the watts per cubic centimetre and the ampere-turns per centimetre of tooth (or flux density in slots), and all the curves are exponential

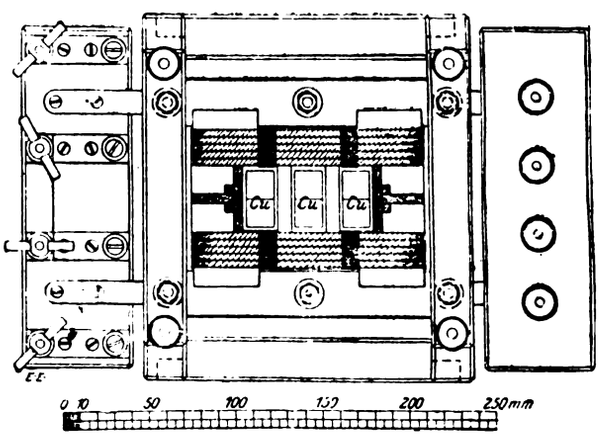

FIG. 3.

functions of the abscissæ, the exponential index working out at approximately 2. It will be noticed that the losses when the copper is subdivided crosswise appear to be slightly greater than when it is solid. This is, however, probably accounted for by the fact that in the former case the platinum thermometer could be inserted in the middle of the bar, whilst in the latter it could only be laid beside the bar, and so did not quite reach the temperature of the bar. The losses with the double bar and the four-fold bar are practically alike, showing that crosswise subdivision has little if any effect. This indicates that the flux passes practically straight down the slot.

Digitized by Google

In the case of the cable (VI.) the ends had to be soldered, and it is likely that the losses would have been negligibly small but for this soldering. Fig. 6 shows the connection between watts lost per cubic centimetre and width of

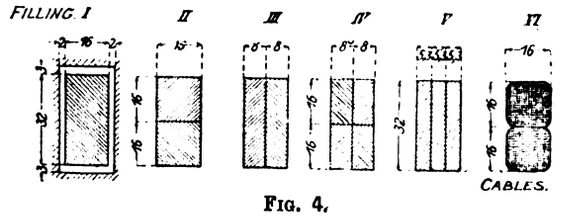

FIG. 4.

copper conductor for the fillings Nos. II, III., and V. at various excitations. The exponential index for these curves averages 1·5. Theoretically, the eddy-current loss per one cubic centimetre is given by the expression $2{\cdot}11 \times \gamma \times \nu^2 \times f^2 \left(\frac{A}{l}\right)^2 \times S^2 \times 10^{-7}$ in watts, whilst from the average of the experimental results the formula is

$$2{\cdot}12 \times \gamma \times \nu^2 \times f^2 \times \left(\frac{A}{l}\right)^2 \times S^{1{\cdot}5} \times 10^{-7},$$

and the exact agreement of the constants is remarkable.

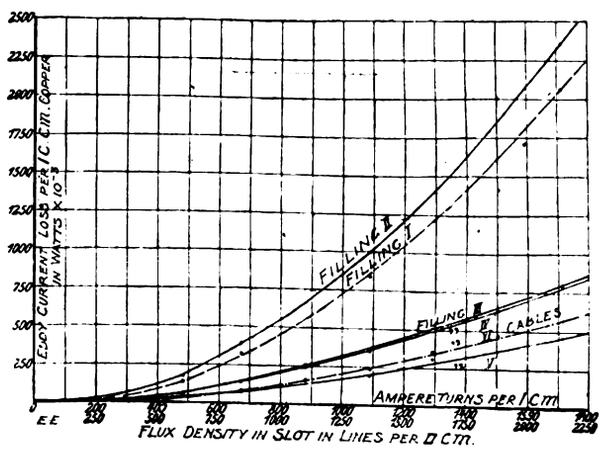

FIG. 5.

γ = specific conductivity in C.G.S. units = $\cdot 58 \times 10^{-3}$ for copper at 15deg. C.;

ν = periodicity (which was 50 in the tests);

f = form factor of the curve of E M F. induced by the slot flux;

$\frac{A}{l}$ = ampere-turns per 1cm. of length of tooth (or slot);

S = width of rectangular conductor in centimetres measured at right angles to the direction of the flux.

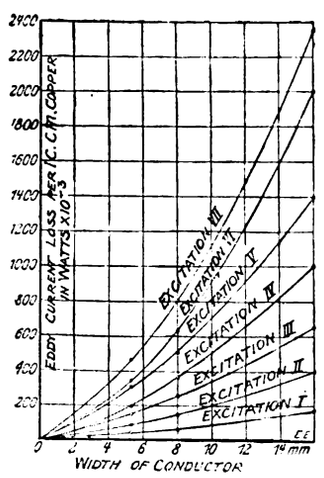

FIG. 6.

As regards the practical application of the above results to actual armatures, it must be remembered that in these tests the flux passed straight down the slot, whilst in an armature, as soon as a slot passes out from under the pole-piece, a cross flux is set up, the effect of which is obviously not related to the thickness of the copper in the same way as that of the straight down flux. Still, the curves given will serve to indicate the approximate eddy-current losses to be expected in any particular case. The ampere-turns per centimetre in place of the flux densities in the teeth have been employed in the formula because it is the former which actually determine the flux density in the slot, and, therefore, the eddy currents in the conductor, whilst the effect of the tooth flux density on the losses is indefinite, and depends on the quality of the iron. The presence of the form factor in the formula enables the effect of various polar flux distributions to be compared, and indicates that flat flux curves are more unfavourable than those produced by bevelled-off pole-tips, not directly because the flux differences within a slot at the pole-tip are reduced, but because the maximum eddy-current voltage is reduced owing to the more uniform rate of change of flux.

BOLTON ELECTRICITY ACCOUNTS.

The accounts of the Bolton electricity department for the year ended March 31, 1905, show a total expenditure on capital account to that date of £256,820. Abstracts of the revenue account, balance-sheet, etc. are appended.

REVENUE ACCOUNT.

PERSONAL.

The Bradford Tramways Traffic and Fares Sub-Committee recommend the appointment of Mr. T. Stirk, chief assistant in the traffic department, to the post of traffic superintendent.

The recommendation of the Coventry Electricity Committee to increase the salary of Mr. J. A. Jeckell from £400 to £450 per annum, as announced in our issue of Sept. 15, was agreed to by the Town Council at their last meeting.

Mr. Oswald Dewey, who has been for some time on the outside staff of Messrs. Ferranti Limited, Hollinwood, is about to join the Ressin Manufacturing Co. to take charge of their office at 14, New-street, Birmingham, and to represent them in the Midland district.

Mr. William Bruce Dick, of Carrick Grange, Sevenoaks, Kent, largely interested in Messrs. Dick, Kerr, and Co., permanent-way contractors and electrical engineers, of 110, Cannon-street, and Kilmarnock, who died on July 11 last, aged 75, founder of the firm of Dick, Kerr, and Co., left estate valued at £233 349. 2s. 7d. gross in the United Kingdom, of which £157,979. 16s. 11d. is net personalty.

On Friday last at the Ilford electricity works Mr. J. L. Smith, late shift engineer, was presented with a handsome case of drawing instruments, suitably inscribed, by Mr. A. H. Shaw, chief electrical engineer, on behalf of the staff and employés. Mr. Smith has recently been appointed shift engineer to the Stepney Borough Council. Mr. W. H. Taylor succeeds Mr. Smith at Ilford.

Mr. James MacIntosh, B.Sc., A.M.I.C.E., has been appointed lecturer to evening classes in electrical engineering at the Battersea Polytechnic. Mr. MacIntosh studied electrical engineering at Glasgow University, when he took the degree of B.Sc., and was trained in the works of Messrs. Kelvin and White, being for some time in Lord Kelvin's laboratory. He is at present chief assistant to the manager of the Alliance Electrical Co., in charge of the engineering department, and is the inventor of an automatic booster.

Mr. W. H. Jay, district superintendent of the County of Durham Electrical Power Distribution Co., has been the recipient of a handsome suitably-inscribed timepiece, presented to him by the chief assistant, Mr. J. Husband, on behalf of the staff, on the occasion of his leaving Durham to take up the post of district engineer of the Gosforth and Benton area under the Newcastle-on-Tyne Electrical Power Distribution Co. Mr. Jay is succeeded as district superintendent at Durham by Mr. W. S. Verrill, late of the Newcastle-on-Tyne Electrical Supply Co.

LEGAL INTELLIGENCE.

THEFT OF ELECTRICAL FITTINGS.

At the Thames Police Court on Tuesday, Henry Lofthouse, an electrician, was charged with stealing a quantity of electrical fittings, valued at £50, belonging to the proprietors of the Bow Palace of Varieties Theatre.

Prisoner was employed at the theatre as electrician. In the engine-room were fittings in connection with a dynamo and other machines, and these Mr. C. Harley, the manager, saw safe on the 7th inst. On the 11th they were missed, and accused left without giving notice.

Mr. Dickinson sentenced prisoner to four months' hard labour.

COMPANIES' MEETINGS AND REPORTS

YORKSHIRE ELECTRIC POWER.

The fifth half-yearly meeting of this Company was held on Tuesday, Mr. A. G. Lupton presiding.

The CHAIRMAN said the directors hoped that the shareholders would visit the works and see for themselves the progress that had been made in the development of the undertaking. Alluding to the accounts, he said the share capital had been increased by 1,575 shares, which had been issued to Callender's Cable Co. for work done by them. The last call on 19,750 ordinary shares was due in March, and the whole of the calls were paid up with the exception of the call on 52 shares. It had been necessary to organise a considerable staff to superintend the laying of the mains and canvass the district which they were serving. It had caused considerable expenditure, but it was bearing fruit in the rapid development of the undertaking. In February he reported that agreements had been made with customers to the amount of over 900 h.p. These were now connected with the mains, and they had further agreements with consumers and negotiations with others to quite as large an amount. Mr. Woodhouse, their resident engineer, assured them—and the directors thought it was upon good grounds—that the revenue during the year ending June 30, 1906, would meet all the expenditure with the exception of the depreciation sum and interest on capital. They found that those consumers who had experienced a few months of the Company's supply were quite satisfied, and in individual cases they were extending the use of the motive power. That was the best sign they could have. They were supplying three textile factories and several collieries. He believed local authorities were beginning now to realise that the Company could supply electricity on a much cheaper basis than they could possibly hope to generate it themselves, and they were finding an increasing demand from them. At their last meeting he reported that there were two Bills which they should probably have to fight in Parliament. He was glad to say that in both instances clauses were introduced which made it unnecessary for them to do so. There had not been a single share sold by the directors from the beginning, but they had increased their holdings by purchasing shares which had been offered to them.

The report was adopted, and the directors were authorised to borrow sums not exceeding £80,000 by the issue of debenture stock.

SIR W. G. ARMSTRONG, WHITWORTH, AND CO.

The tenth annual report states that for the year ended June 30 last, after deducting depreciation and adding £86,369 from last year, there remains a profit of £530,927 on the year's operations. It is proposed to declare on the ordinary shares a dividend of 3s per share, of which 1s. per share has been already paid as interim dividend, and to carry forward £84,033. The directors state that the establishments of the Company are well supplied with orders. In continuance of the past policy, the sum of £15 000 has been placed to the credit of the account for the renewal of plant. The directors have decided that the comparatively small sum in the books of the Company representing goodwill should be eliminated. They had, therefore, applied the sum of £13,710 to this purpose, and goodwill is now extinguished.

WILLANS AND ROBINSON.

The report of Willans and Robinson for the half-year ended June 30 last, to be submitted at the meeting on the 4th prox., shows a loss of £8,617 at Rugby and £14,285 at Queen's Ferry, or £22,902 in all. As the provision for depreciation at the two places amounts to £17,742 and £5,929 represents the valuing down of certain stocks, the actual reduction in the liquid assets of the Company, as distinct from a book loss, is £1 231. As the debit balance brought forward on profit and loss account was £79,952, there is now a debit balance to carry forward of £102,854. Trade in high-speed engines has continued to be unprofitable, and the new classes of work taken up have not advanced far enough to produce any substantial advantage in the accounts. Of the gas-engine business it can only be said that, while much expense has been incurred, there is not yet sufficient evidence of a commercially profitable result to follow. As regards steam turbines, the directors are satisfied that a successful business is assured. The turbines which have been set to work have done extremely well, and this initial success will, in their opinion, lead to a rapid development of the business. The steelworks at Queen's Ferry were restarted in January, and during the half-year have not only contributed to the general expenses of the business, but have yielded a small profit. The special steels made by the Company are attracting increased attention, and there is a good prospect of satis-

Digitized by Google

factory business in the future. The orders for boilers are sufficient to keep the remainder of the works employed upon the moderate scale to which it is at present considered advisable to limit operations. In weighing the real loss at Queen's Ferry it is necessary not only to take into account the amount charged for depreciation and for writing down of old stocks, but the fact that Queen's Ferry is charged to the extent of nearly £3,000, with its due proportion of certain general charges, which, if Queen's Ferry were not at work, would still have to be paid. The directors are satisfied that the best policy is to continue to keep the Queen's Ferry works open and to develop the business as opportunity serves.

MERSEY RAILWAY.

The report for the half-year ended June 30 states that the train mileage run during the half-year was 412,215 miles, as compared with 411,683 during the corresponding six months of 1904. The number of passengers conveyed during the half-year ended June 30 has been 4,862 378, as against 4,499,147 for the corresponding period of 1904, exclusive of season-ticket holders. The total receipts from all sources have been £43 536, as compared with £40,918 for the corresponding period of 1904. The working expenses, exclusive of the charges for pumping, ventilation, and lifts, have been £30 779, equal to 70 70 per cent., as against £29 751, equal to 72 71 per cent. for the corresponding six months. These charges for pumping, ventilation, and hydraulic lifts amounted to £3,949, equal to 9·07 per cent., as compared with £3,839, or at the rate of 9·38 per cent. for the corresponding period of 1904. Since the closing of the accounts the 4½ per cent. redeemable first debenture stock, amounting to £249,276, has been redeemed by the issue of 4 per cent. Mersey Railway new first perpetual debenture stock in terms of the Act of 1900 and the contract with the British Westinghouse Electric and Manufacturing Co. A service of motor omnibuses to and from the stations of the Company in Birkenhead is being arranged for and will shortly be inaugurated.

APPOINTMENTS VACANT.

Canvasser, Batteresa Electricity Department. Applications by Oct. 10. See advertisement.

Electrical Fitter and Repairer, West Africa. Salary, £20 per month. See advertisement in last issue.

Junior Engineers for a company in the Metropolitan district. Apply to B. W., *Electrical Engineer* Office. See advertisement.

Engineering Instructor. the Technical Education Board of Wellington, New Zealand. Salary, £300 and £40 passage allowance.

Assistant for electrical estimating department in large switchworks. Applications to Box H 2, *Electrical Engineer* Office. See advertisement.

Charge Engineer, Willesden Urban District Council. Salary, 35s. per week. Applications by Oct. 4. See advertisement in last issue.

Winders for direct-current and alternating-current work. Apply to Bruce Peebles and Co., East Pilton, Edinburgh. See advertisement in last issue.

Assistant Engineer to act as station superintendent at one of the Edinburgh Corporation's electric generating stations. Commencing salary £180 per annum, rising to a maximum of £270 per annum. Applications by Oct. 2. See advertisement in last issue.

FORTHCOMING EVENTS.

THURSDAY, OCT. 5.

Rugby Engineering Society.—At 8 p.m., general meeting, with lecture by Mr. J. Sugden, entitled "Protection from Electric Shock," to be supplemented by a practical demonstration of the necessary treatment after a shock.

MONDAY, OCT. 9.

Lancashire Electric Power Company.—At 1 p.m., opening of the Radcliffe power station by the Earl of Derby

LIENS REGISTERED AND DISCHARGED.

New General Traction Co., Limited.—A memorandum of satisfaction to the extent of £18,700 of debentures, dated July 8, 1901, securing £200,000, has been filed.

Llandrindod Wells Electric Light and Power Co, Limited, Chester.—Debenture and mortgage, as collateral security registered Sept. 13, for £4,000, pursuant to an order of the High Court of Justice dated Aug. 30, 1905; charged on the undertaking and all the property, present and future.

Electrical Bleaching Co. (1904), Limited, Manchester.—Mortgage registered Sept. 14, for an indefinite amount, the instrument being stamped to cover £10,000 to the Manchester and Liverpool District Banking Co., Limited; charged on messuages, tenements, and other hereditaments, with fixed plant and machinery in Tottington Higher-end, Lancashire, subject to debentures for £14,000.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Paris.—The Post and Telegraphs Department, 13, Rue de Grenelle, require tenders for insulators, cables, etc. Tenders by Oct. 10.

Paris.—The Post and Telegraphs Department, 13, Rue de Grenelle, require tenders for copper and bronze wire and other telegraph material. Tenders by Oct. 9.

Pontypridd.—The Urban District Council invite tenders for (Section B) overhead equipment for tramways; (C) cables for tramways. Tenders by noon on Sept. 30.

Prestwich (Lancs.).—The Urban District Council invite tenders for the installation of electric light in their Council Offices, Prestwich. Tenders by 12 noon on Oct. 9.

Paris.—The Colonial Office, 4 rue Jean Nicot, Paris, require tenders for galvanised iron wire for the Indo-China telegraph service. Tenders by Oct. 10. Specification from Inspection Générale des Travaux publics, room No. 146, at above address.

Langho (near Blackburn).—The Chorlton and Manchester Joint Asylum Committee invite tenders for the supply and fixing of the necessary telephones and electric bells at the new colony for epileptics at Langho, near Blackburn. Tenders to the Clerk, Chorlton Union Offices, All Saints', Manchester, by Oct. 3.

London County Council.—The London County Council invites tenders for the manufacture and laying of (*a*) 56 miles low-tension lead-covered, paper-insulated cables, 20 miles dry-core telephone cables, cast-iron feeder pillars, etc.; (*b*) 24 miles extra high-tension three-core, lead-covered, paper insulated cables, etc. Tenders to Mr. G. L. Gomme clerk, by 10 a.m. on Oct. 3.

Great Western Railway.—The directors of this company invite tenders for the supply of various stores from Dec. 1 next to Nov. 30, 1906. Specification, with forms of tender, may be obtained at the office of the Stores Superintendent at Swindon. Tenders to Mr. G. K. Mills, secretary, Paddington Station, London, by Oct. 16. Full particulars in advertisement columns.

Southgate.—The Light Railways and Tramways Committee of the Middlesex County Council invite tenders for the work and materials required in the construction of the permanent way (for electric traction), bridge work, road widenings, etc., for Contract No. 14; railway No. 2 (order 1900)—a line of double track (with crossovers, contingent works, etc.) to be laid along Bounds Green-road, in the district of Wood Green, and High-road, Southgate, to a length of 1 mile 5 furlongs 1 chain, or thereabouts. Tenders to Sir Richard Nicholson, clerk of the County Council, Middlesex Guildhall, Westminster, S.W., by Oct. 4.

RESULTS OF TENDERS.

Finchley.—The Urban District Council have accepted the tender of the British Accumulator Co., Parliament Mansions, Victoria-street, London, S.W., at £2,761. 10s., for two large storage batteries required at their new sub-station.

Southend.—The Town Council have accepted the tender of the Chloride Electrical Storage Co., at £445, for the dismantling and renewal of the battery (less a sum of £35 to be allowed by them for old material, subject to the Corporation paying carriage to London), and for the maintenance of the battery for a period of 10 years at the rate of £35. 10s. per annum.

Recent Contracts.—Messrs. Dick, Kerr, and Co. report the following recent contracts: J. Kenyon and Son, complete generating plant and motors for driving spinning mills; Cammell, Laird, and Co., 300-kw. D.C. generator; Wallasey Urban District Council, five single-deck cars with top covers, complete with electrical equipments; Ashton, 500-kw. D.C. generator; Star Papermills, complete generating plant and motors for driving the mills; Buenos Ayres Port and City Tramways, 24 double service cars and equipments, 10 combined freight cars and electric locomotives; Cawnpore Tramways, 20 single-deck cars and equipments; London County Council, 16 single-deck steel cars, specially designed for L.C.C. subway.

Ramsgate.—The Corporation have received the following tenders for electric call bells:

J. Bussey, Ramsgate	£137 10 0
Telephone and Electrical Installation Co., London	115 0 0
National Telephone Co., Ramsgate	110 0 0
Electrical Engineering Co., London	109 0 0
Stuart and Moore, London	106 15 6
E. Coveney, Ramsgate	90 0 0
E. J. Philpott, Ramsgate (accepted)	77 16 0
G. Poulson, Ramsgate	58 10 0

Maintenance per annum: Telephone and Electrical Installation Co., £18; National Telephone Co., £7. 10s.; Stuart and Moore, £10; E. Coveney, £9; E. J. Philpott, £4. 10s.; G. Poulson, £2.

Croydon.—The County Council have received the following tenders for the supply of three electric motors and pumps at the farm:

T. Harding, Churton, and Co. (accepted)	£292 0 0
Witting, Eborall, and Co.	296 0 0
Fuller, Wenstrom, and Co.	310 4 0
Gwynnes Limited	345 0 0
Rhodes Electrical Co.	359 0 0
Worthington Pump Co.	353 10 0
J. H. Holmes and Co.	363 0 0
Korting Bros.	376 10 0
Laing, Wharton, and Co.	390 0 0
A. Schove	403 0 0
J. Gordon and Co.	387 0 0
Mather and Platt	405 0 0
Lahmeyer Electrical Co.	406 16 6
W. H. Allen and Son	480 0 0

Digitized by Google

BUSINESS NOTES.

TRACTION.

Belfast.—A successful trip was made on Tuesday.

Newcastle.—The lines for the Scotswood extension are being welded by the Goldschmidt thermit process.

Durham.—The Rural District Council have decided to withhold their consent to a further extension of time for completing the Durham and district light railways.

Wellington (New Zealand).—As stated under "Imperial Notes" elsewhere in this issue, the City Council intend to add to the tramways power plant at an early date.

Southend.—The Tramways Committee have resolved to recommend: "That the Council do approve in principle the extension of the tramways system along High-street, Pier-hill, and Marine-parade."

Glasgow.—A large deputation last week waited upon the Tramways Committee, who stated that they would endeavour to bring the question of an extension to Millerston before the Corporation at an early date.

District Railway. — To avoid further accidents, the District Railway Co. are now fitting their electric trains with steel flaps, so that it will be impossible for anyone to get caught between the cars while walking from one to another.

Devonport —At the meeting of the Tramways Committee the scheme for constructing a light railway to Crown-hill came up for discussion, but it was considered unwise to come to any decision until further information is received from the engineer.

Keighley.—From July 1 to Sept. 7 the number of passengers carried on the Corporation trams was 358,921, and the receipts totalled £1 523. 10s., or 7·25d. per car mile. This gives an average of nearly £153 a week, and the committee estimate that at £150 a week the system is self-supporting.

Musselburgh.—The National Electric Traction Co., which laid down the tramways between Joppa and Musselburgh, propose to extend the system eastward from Levenhall to Cockenzie, a distance of about five miles. Mr. E. A. Mitchell, chief engineer to the company, has commenced a survey of the route.

Dunfermline.—Some weeks ago the two companies interested in the laying down of tramways in the Dunfermline district resolved, notwithstanding the County Council strictures, to proceed with their application for a provisional order. On Monday several gentlemen connected with the local company motored over the proposed routes.

Perth.—At the meeting of the Town Council on Monday night, when the fares were fixed, a general consensus of opinion was expressed that a Sunday service of cars should be inaugurated, Lord Provost Love strongly dissenting. A proposal to introduce ½d. stages was defeated, and the fares will remain as at present. The centre of the system is to be the Cross.

Bradford.—A proposal will shortly come before the Bradford Tramways Committee to enter into arrangements with the Mid-Yorkshire Tramways Co. for the issuing of return tickets between Bradford and Dewsbury. Heckmondwike, Batley, and Birstall. It is proposed to charge for the return journey to Dewsbury 1s., to Heckmondwike and Batley 10d., and to Birstall 8d. These charges are much less than the ordinary fares on the railway.

Croydon.—At the meeting of the Town Council it was resolved that a double line from the present terminus to Penge be constructed forthwith. It is proposed that the Thornton Heath line shall be extended. Notice has been served upon the British Electric Traction Co. terminating their lease on May 31 next. The company have made an offer for a renewal of the lease on the basis of 7 per cent. instead of the present 6½ per cent. return on the Corporation's capital expenditure, an increased yearly payment in respect of road repairs, and a quarter of the net profits.

Liverpool Overhead Railway.—A rather curious mishap occurred on the Liverpool Overhead Railway, one of the axles of a train snapping. One account states that in consequence of the axle breaking the body of the carriage became depressed, and a disused rail lying underneath the working track was caught up, carried some distance, and then crashed through the floor of the coach. The carriage was full of working-men travelling to the various docks. Three were injured, but fortunately not seriously. Another version is to the effect that the two ends of the broken axle were driven through the floor.

Torquay.—At the meeting of the Town Council on Monday there was a lengthy discussion on the tramways question. The Dolter Co. asked for the approval of the Council to an alteration in the proposed routes, but the Council decided that they would only agree to this deviation on consideration that the company undertook to relieve them of their obligation to provide electric current for the trams in the event of the Local Government Board refusing to grant the loan of £9,500 which is now being asked for for the extension of the present electricity station, so as to enable the Council to produce the necessary power.

Grimsby.—A deputation has been appointed to wait on the directors of the Provincial Tramways Co. on Oct. 6 in London. They have been instructed to proceed on the following lines: (1) That purchase shall be completed at once. (2) That an agreement be entered into between the tramways company and the Council for the tramways company to pay depreciation from April 3, 1905, until the passing of the proposed Bill to enable the company to take a lease, and the company to pay all working expenses until the proposed lease is executed. (3) That an agreement be entered into for the purchase of the arc lamps and the standards erected by the company; also for the supply of current for public lighting.

Potteries Electric Traction Co.—At Stoke-on-Trent last week a conference of representatives of local authorities whose areas are traversed by the lines of the Potteries Electric Traction Co. was held to consider various alleged nuisances caused by the tramcars of the company. Mr. G. Ralley, mayor of Stoke, presided, and in opening the meeting expressed a hope that the deliberations of the conference would be productive of much good in the way of remedying the nuisances caused by the noise and rattle of the tramcars passing through their respective districts. It was decided to appoint a deputation from the conference to wait upon the manager of the company and lay the whole matter before him, and then, if they could not get satisfaction, they should petition the Board of Trade to hold an inquiry to see if the trams were worked on the most skilful method.

All-Steel Railway Carriages.—In a communication to the *Times* Mr. B. Broadhurst, secretary to the Brush Electrical Engineering Co., states: "We regret to observe from the letter of Mr. Granville C. Cuningham that we were in error in supposing that no steel cars had previously been made in this country. It was, however, practically in response to the demand for certain railways whose managers stated that they were unable to obtain all-steel rolling stock in England that we set out to fill what we honestly believed to be a vacancy. The highest credit is due to Mr. Cuningham, whose enterprising management of the Central London Railway has been of great educational value in electric railway practice; but until we started constructing steel coaches it does not appear that any British manufacturer made any effort whatever to draw attention to their conspicuous advantages, and in the meantime large orders were being placed in America."

Manchester Carriage and Tramway Co.—At a meeting of the shareholders, Mr. Hamilton, solicitor to the company, submitted the statement of affairs, and referred to the appeal pending between the company and the Salford Corporation as to the Swinton and Pendlebury tramways, which have been adopted by the Corporation. The award of the arbitrator, Sir Frederick Bramwell, was in favour of the company, but this was upset by the Court of Appeal, and the company had now gone to the House of Lords on the question. It was expected that the case would be heard early next year, and until it was disposed of no final statement of the company's affairs could be rendered. With the money in hand, however, it was expected that a further payment would be made to the shareholders towards the end of November. A liquidator will be appointed in the place of Sir John Harwood at a future meeting. It is understood that by the time the company is finally wound up the shareholders will have received upwards of £1,000,000 as a result of the liquidation.

Walsall.—The following are the particulars of the working of the tramways during the five weeks ending Sept. 3, 1904, and the corresponding period of this year respectively: passengers, 466,927; receipts, £2 617. 8s. 11d.; car miles run, 59,827·07; receipts per car mile run, 10·49. Passengers, 481,872; receipts, £2,707. 9s.; car miles run, 62,593·27; receipts per car mile run, 10·38. Wages paid (including repair of permanent way): for five weeks ending Sept. 1, 1904, £778. 4s. 2d.; for five weeks ending Aug. 30, 1905, £813. 12s. 10d. In response to a petition, signed by all the drivers and conductors, the Corporation have resolved to allow all the tramway employés, including those engaged in the shed, four days holiday a year with wages after two years' service and five days holiday a year with wages after three years' service, the period of service to count from the time each employé was engaged by the Corporation. The cost of these concessions is about £120 a year. The Corporation are unable to grant the men's application for Sunday work to be considered as time and quarter.

Chester.—At a meeting of the Tramways Committee the city surveyor reported that the gas company had again referred to the question of the company's mains, which will lie under the proposed tramway track. The company had suggested that a portion of the main in Boughton should be removed to a new position, and that additional rider mains should be laid in the Tarvin and Christleton roads. The town clerk reported regarding an interview he and the city surveyor had had with the manager of the company on the subject, when the latter intimated that he was prepared to advise his company to contribute something to the cost of the alteration of the mains. The city surveyor having shown on plans the positions of the gas and water mains—co-extensive with the proposed tramway track—it was, after discussion, resolved that the town clerk and the city surveyor enter into negotiations with the gas and water companies with the view of ascertaining the terms on which it can be arranged for the lines of the existing mains in Boughton, Tarvin-road, and Christleton-road to be so altered as to remove them, as far as possible, from the line of the proposed tramway track, and that they report thereon to the next meeting.

London County Council.—The Poplar Borough Council has decided to consent to the overhead system, and it is not improbable that the Stepney Borough Council will follow suit. The line from the Archway Tavern to Highgate Archway, undertaken by the London and Middlesex County Councils jointly, has been completed, as also have the extensions from Green-lanes to the Alexandra Palace. The Hammersmith Borough Council have decided to give their support to the County Council's Embankment scheme. The Bermondsey Borough Council have assented to the construction of loop lines on the Grange-road section. The Board of Trade, in response to representations from the Camberwell Borough Council, have intimated that they consider a 1in. slot for the conduit system preferable to a ¾in. slot. The County Council are to use silent paving material in Camberwell in front of public buildings, as well as in front of churches and hospitals, and to use granite setts instead of wood for paving the margins of the track where the roads are formed with macadam. A resolution is to be submitted to the Camberwell Borough Council recommending that now that the London, Camberwell, and Dulwich Tramways Co. no longer form an obstacle, the County Council shall obtain powers for continuing their authorised line as far as the Crystal Palace, *via* Lordship-lane.

Digitized by Google

Maidstone.—At the monthly meeting of the Urban District Council the following recommendations were adopted: "(*a*) That the Board of Trade be asked to confirm the order of the Light Railway Commissioners so far as that portion of the proposed line is concerned which relates to Upper Stone-street and Loose, and that permission be requested to allow the same to be immediately commenced on the Corporation giving an undertaking to proceed at once with the necessary application to the Light Railway Commissioners for an extension connecting the existing line in High-street with the proposed new line, *via* Mill-street and Knightrider-street. (*b*) That application be made in November next to the Light Railway Commissioners for an order authorising such extension as aforesaid from High-street along Mill-street and Knightrider-street, to the bottom of Upper Stone-street. (*c*) That an application be also made in November next to the Light Railway Commissioners for an order authorising an extension from High-street along Mill-street College-road, King Edward-road, and Old Tovil road to Tovil. (*d*) That the Board of Trade be asked to confirm the order of the Light Railway Commissioners so far as relates to the line from Week-street to Boxley-road, with a clause suspending the work of construction until a suitable connection with the existing system is authorised." There is a net profit on the year's working of £1,531, and the engineer is to be consulted as to the formation of a renewals fund.

Hythe.—In reference to our note last week upon the Traction Corporation's proposal for an electric tramway on the Kingsland surface-contact system for Hythe, Folkestone, and Sandgate, the following are some particulars of the project. The company estimate that a single line could be constructed for £110,000, but consider that double track would be greatly preferable. The costs of construction would be borne by the local authorities, the company offering to negotiate the loan at interest not exceeding 4 per cent. The Traction Corporation offer to form a company on these conditions: "(1) The interest on the loan and redemption fund to be first charges on the profits of the operating company; (2) the operating company then to take 5 per cent. on its share capital; (3) balance of profits to be divided as to one-half to the corporations, and as to the other half to the operating company; (4) the division of profits between the three corporations might be in proportion to the number of car miles in their respective districts, or in proportion to the track mileage, or in any other way to be mutually agreed between the corporations; (5) the capital of the operating company to be fixed by agreement with the corporations." The company estimate a car mileage of 600,000 or more per annum. The receipts are put at 10*d*. per mile and the working expenses at 5½*d*., leaving a profit of £11,250. Loan charges would absorb about £5,500, leaving some £5,700 to be divided between the local authorities and the company. The Traction Corporation recommend that, to save capital expenditure, energy should be taken from the local supply company if it can be had at 1*d*. per unit.

Electric Signalling.—An attempt to cope with the difficulties of railway signalling in foggy weather by electrical means has been essayed by Mr. Elijah Burgoyne, of Nottingham, and the local Press contains the following description of his system: "Electricity plays an important part in the scheme. By an ingenious plan, directly danger is signalled, or the necessity of proceeding cautiously, a gong of different tone sounds on the engine itself, and an immense 'bullseye' on the cab glares with red or green light in the driver's face. Even the densest fog would thus be robbed of its danger, provided there was no failure in the apparatus or supply of the electric current. In theory the idea is effectiveness itself. Beyond the spot where at present the distant signal is situate Mr. Burgoyne proposes that a central rail 100 yards in length should be laid, with a second and much longer central rail near the present home signal. Connected electrically with the signal-box, the pressure of a roller beneath the engine on these central metals would not only ring a bell and cause a lamp (corresponding with the line upon which the train was running) to glow in the signal-box, but bells would ring, and red or green lamps glow on the engine itself, the colour of the lamp depending upon which rail (the right or left) the signalman had converted into a negative. Mr. Burgoyne's model is fitted up in a room at home, and is somewhat crude. Yet the crudeness of a model does not affect the inherent value of an invention, and Mr. Burgoyne states that at least one expert in signalling has pronounced most favourably on his invention, both as regards its simplicity and utility." At present the chief obstacle appears to be expense, besides which the old problem of the "human equation" remains, as the drivers might rely entirely upon the ringing of the gong without taking note of their whereabouts. Still, electricity is coming into favour for signalling purposes, and it will be interesting to watch developments.

Tramway Expansion.—A report by the Board of Trade of their proceedings under the Tramways Act, 1870, during 1905, has just been issued. The number of applications made to the Board of Trade in December, 1904, for provisional orders under the Act was 12—viz.: Aberavon District, Bradford Corporation, Colchester Corporation, Gorton Urban District Council, Keighley Corporation, King's Norton and Northfield Urban District Council, Leeds Corporation, Liverpool Corporation, Luton Corporation, Portobello and Musselburgh, Pudsey Corporation, and Southampton Corporaton. Eleven of the applications included power to construct new or extension tramways, the remaining one—Portobello and Musselburgh order—being to amend a previous order in certain respects. All except two—Aberavon District and Portobello and Musselburgh—were promoted by local authorities. The aggregate length of the proposed tramways was 11 miles 27 chains of double line and 16 miles 52 chains of single line, and the estimated expenditure was £321,226. In the House of Lords the following orders were petitioned against—viz.: (1) Aberavon order, by the Glamorgan County Council and the Great Western Railway Co.; (2) Colchester order, by the National Telephone Co.; (3) Gorton order, by the National Telephone Co.; (4) King's Norton and Northfield order, by the National Telephone Co.; (5) Leeds order, by the Great Northern Railway Co.; (6) Luton order, by the Midland Railway Co.; (7) Portobello and Musselburgh order, by the National Telephone Co.; and (8) Pudsey order, by the Great Northern Railway Co. The Aberavon order was withdrawn, and the opposition of the National Telephone Co. was met by the insertion of special amendments. The amendments desired by the railway companies in the cases of the Leeds, Luton, and Pudsey orders were not accepted by the committee. These amendments consisted mainly of a provision against danger from the falling of railway signalling wires on to the electric tramway wires. The railway companies were dissatisfied with the decision of the committee, and proposed to renew their opposition in the next House. With the assent, however, of both parties, a hearing was held at the Board of Trade, as the result of which a modified form of the clause was settled by the Board of Trade and inserted in the orders mentioned, and also in the Bradford Corporation order. The following orders were petitioned against in the House of Commons—viz.: (1) Bradford order, by the Lancashire and Yorkshire Railway Co.; (2) Leeds order, by the Great Northern Railway Co.; and (3) Pudsey order, by the Great Northern Railway Co. The opposition was, however, withdrawn on the insertion in the orders of the amendments before referred to and of amendments agreed upon between the parties.

LIGHTING AND GENERAL.

Mitchelstown.—Consideration of the electric lighting of the town has been adjourned for one month.

Lancashire Electric Power Co.—The company's power station at Radcliffe will be opened by Lord Derby on Oct. 9.

Babcock and Wilcox.—The directors have declared an interim dividend of 1*s*. 7½*d*. per share on the ordinary shares.

Bridgwater.—The question *re* the installation of the electric light in the chancel of St. Mary's Church has now been settled.

Rawtenstall.—An inquiry has been held into an application for sanction to borrow £12,000 for the purpose of electric lighting.

Bourne.—A scheme for lighting the town with electricity is being discussed by the Urban District Council and the tradesmen's association.

Hammersmith.—The report recommending a reduction in the charge for current, noted in our last issue, has been adopted by the Borough Council.

Swinton.—The agreement between the Swinton and Pendlebury Urban District Council and the Lancashire Electric Power Co. is about to be ratified.

Bridlington.—The Town Council have decided to borrow £4,500 for purposes of the extension of the electricity works. The total number of lights now supplied aggregate 10,211 8 c.p.

Hove Electric Lighting Co.—The directors have declared an interim dividend on the paid-up share capital of the company at the rate of 8 per cent. per annum for the half-year ended June 30.

Agency.—We are informed that Messrs. Andrew Brown and Co., 110, Cannon-street, E.C., are the sole representatives of Messrs. Franz Meguin and Co. for the supply of their perforated metals and embossed plates.

Stock Exchange.—The Stock Exchange Committee have been asked to allow the Bournemouth and Poole Electricity Supply Company's further issue of 3,000 ordinary shares of £10 each, fully paid, Nos. 27,001 to 30,000, to be quoted in the official list.

New Publications.—Dr. Mullineux Walmsley has rewritten and enlarged his well known treatise on "Electricity in the Service of Man" so as to bring it up to date, and Messrs. Cassell and Co. are issuing the work in parts at 6*d*. per number. As before, the subject is treated in a lucid style, and is profusely illustrated. "Building Construction," by Prof. H. Adams, is the title of a volume dealing with materials, processes, principles, and the practice of building construction. This treatise is also being published in parts by Messrs. Cassell and Co. at 3*d*.

Tunbridge Wells.—The proposal to dispose of the municipal electricity undertaking to a private company came before a mass meeting of ratepayers at the town hall on Wednesday. The following resolution was carried: "That in the opinion of this meeting any step taken towards the sale or transfer of the Corporation electricity undertaking to a private company would be detrimental to the best interests of the borough and to the users of electrical energy. This meeting, therefore, urges upon its representatives on the Town Council to oppose any motion in favour of such action."

Blackburn.—Mr. P. P. Wheelwright, A.I.E.E., the borough electrical engineer, recently organised an electrical exhibition, which was held from Sept. 16 to 23, and which was visited by 13,000 people. This exhibition was organised in order to bring before the public the advantages to be gained by the use of electric light and power. The opening ceremony was performed by Alderman William Thompson, chairman of the Electricity Committee. Various entertainments and interesting electrical and scientific demonstrations were given at frequent intervals. There was also a ladies' orchestra, who performed a daily varying programme. Amongst the exhibitors we note, besides the Blackburn Corporation electrical department, the following firms, mostly all belonging to Blackburn and East Lancashire: Messrs. H. Garstang, J. Boyle Limited, H. H. Jackson and Co., W. Thompson, G. Hamilton, the Beaten Metal Co., H. Bailey and Co., the Howe Electrical Engineering Co., G. H. Shaw and Son, C. T. Briscoe, the National Telephone Co., the New Camera Club, Burrows and Garland, J. Eccles, Smoke Preventer Co., Morton and Co., and R. W. Harrison. From what we hear from all sides, the exhibition, which was exceedingly well arranged, proved a great success in every way.

Digitized by Google

Llanelly.—Subject to the consent of the Local Government Board being obtained to the borrowing of £6,000, the Council will inform the South Wales Power Co. of their intention to take up option B.

Wellington (New Zealand).—The City Council have decided to undertake the lighting of the public streets themselves. Particulars will be found under "Imperial Notes" elsewhere in this issue.

Ramsgate.—The cable laying for the supply of electric light is proceeding. The station of the District Electric Supply Co., at Whitehall, and their offices at Broad-street, have been brilliantly illuminated.

Keighley.—The Town Council are about to lay 280 yards of cable for the supply of power to the works of Mr. Jonas Wells, Longcroft, at an estimated cost of £210. It is expected that the firm will take 60,000 units per annum.

Wellingborough.—Last week a refuse heap at the destructor works took fire, to the great danger of the adjoining generating station of the electric light company. The fire brigade was quickly on the spot and no damage was done.

Trowbridge.—With regard to the question of the electric lighting, it has been agreed to defer further action until Mr. Pearson (Bristol), the Council's legal adviser in connection with the electric lighting, has been interviewed in the matter.

Hove Electric Lighting Co.—The directors have declared an interim dividend on the paid-up share capital of the company, at the rate of 8 per cent. per annum, for the half-year ended June 30 last. The dividend is payable on Oct. 16 next.

Quarry Bank.—The Midland Electric Supply Co. are now giving their present customers at Quarry Bank, Bilston, Darlaston, Ambleoote, Rowley Regis, and Tettenhall, better terms than were anticipated at the time the various agreements were drawn up.

New Company.—Messrs. J. G. Statter and Co., Cornwall-buildings, Newhall-street, Birmingham, are converting their business into a limited company under the name of the Switchgear Co., Limited. We are informed that the personnel, works staff, foremen, etc., remain unchanged.

Lahore.—The Lahore Municipal Committee have decided on electric lighting for the Mall. Messrs. Jessop and Co., Calcutta, have been selected by the Government to carry out the work. They have undertaken to complete the installation before the Royal visit.—*Indian Engineering.*

Hawick.—An electrical exhibition has been held at the town hall by the Urban Electric Supply Co. The proceeds are to go to the cottage hospital. The company started work at Hawick about five years ago, and the consumption is now stated at 28,000 8 c.p., including 300 h.p. for 80 motors.

Battersea.—The Housing Committee, with a view to encouraging the tenants on the Latchmere and Town Hall estates to use the electric light, are arranging for a new 8 c.p. lamp or 16-c.p. lamp to be presented to the tenants for every 60 Board of Trade units of electrical energy consumed by them.

Cardiff.—The chairman (Councillor Chappell) strongly advocates the purchase of an electric launch, with accommodation for 30 or 40 passengers, for use on Roath Park lake, and the Parks Committee have agreed to seek detailed particulars from towns where electric launches are run on the public lakes.

Wembley.—The Urban District Council have decided not to assent to the applications of the North Metropolitan Electrical Power Distribution Co. and the Mutual Electricity Supply Co., and steps will be at once taken to obtain a provisional order authorising the Council to supply electric light within the district.

Exeter.—The Electric Lighting Committee have instructed the town clerk to at once proceed with the application for a provisional order for Heavitree, and to arrange a conference between the committee and the Heavitree Urban Council in view to a decision being arrived at as to the question of "compulsory area."

Bermondsey.—The Electric Lighting Committee reported at the last Borough Council meeting on a letter signed by a number of residents in the immediate neighbourhood, complaining of smoke arising from the working of the dust destructor, that steps were being taken which would no doubt remedy the cause of the complaint.

London Gazette.—Charles James Singleton, 8, Staple Inn London, W.C., has been released from trusteeship in the estate of Charles Manners Downie, electrical engineer, 4, Bloomsbury-street, London. W. Arthur Turner, 21, Bridge-street, Bradford, has been released from trusteeship in the estate of Cecil Wray, mechanical and electrical engineer, 16, Chevin-view, Eccleshill, Bradford.

Walsall.—The total number of consumers supplied on Aug. 31 last was 429. During August 131,562 units were generated at the station. The total output from the main generators was 117,399 units. The total units from the transformers was 90 030 (estimated). The total units registered on the meters was 85,428. The machinery was run for 702 hours. The wages paid amounted to £131.

Southend.—The electrical engineer's last report shows that one Nernst lamp has been fixed and a new circuit of 10 arc lamps put in circuit for the first time. During the last month 71,167 lighting units were generated, as against 52,810 during the same month last year, an increase of 35 per cent. The number of traction units generated was 56,522, as against 55,782, an increase of 1·3 per cent.

Calcutta Electric Supply Co.—The number of units delivered to consumers during the four weeks ended Aug. 25, 1905, were 453,558, compared with 339,738 in the corresponding four weeks of the preceding year. The directors have declared an interim dividend on the paid-up share capital at the rate of 6½ per cent. per annum for the half-year ended June 30, such dividend to be due and payable on Nov. 15 next.

Stoke Newington.—The London County Council have sanctioned the borrowing of £13,750 (£10,000 for cables and machinery and £3 750 for sub-station). The Borough Council will agree, subject to sanction being given to the borrowing of a sum of not less than £20,750, to provide for all renewals and replacements during the currency of the loan out of a sinking fund to be established for the purpose or from maintenance account, and to take up the loan of £5,000 on account of such sum of £20,750, at £5. 7s. 6d. per cent. per annum, repayable in 30 years.

Basingstoke.—The Local Government Board having refused the application for borrowing £16,450 for electric lighting purposes, a resolution, "That the Council proceed forthwith to obtain the further powers by way of provisional order for giving effect to the provisional agreements dated June 24 and 25, 1905, subject to an arrangement being come to that the National Electric Construction Company bear half of the Council's total costs of obtaining such order, in the event of such order not being granted," was proposed at the last meeting and lost by the mayor's casting vote.

Stirling.—The last report by Mr. A. C. Hanson, electrical engineer, shows that for the four weeks ending Sept. 2 18,796 units were generated at the power station, as compared with 12,950 units for the same period in 1904. The total connections in equivalent 8-c.p. lamps were 16,485, as against 15 675 at the same date last year. The engineer is making a trial of an apparatus by George Sinclair, Albion Boiler Works, Leith, for the purpose of preventing the emission of black smoke from the boiler furnaces, at a cost of £12. 10s. per furnace, which is said to effect a saving in fuel of 5 to 10 per cent.

Bo'ness (N.B.).—With regard to the interest on the money that the Council have at various times lying at deposit until it is payable to the electrical company, the Council have asked the company to pay them the difference of the bank interest and the interest the Council are paying on the loan, as the Council are paying 4 per cent. and are only getting 1 per cent. from the bank. We understand that the company have advised the Council that they are willing to meet them on the point. The other demand of the Council that the company should pay an inspecting engineer for an annual inspection remains as yet unsettled.

French Cable.—A Reuter's telegram of Sept. 20 says the Venezuelan Government, in its reply to the French protest against the closing of the French cable station and the expulsion of M. Brun, the manager, states that it holds documents proving that the cable company accepted the result of the judicial proceedings which it took, and that the Government is only waiting to establish new relations between itself and the company. M. Taigny, the French Chargé d'Affaires, knows this, declares the Government, and therefore his protest can only be regarded as an act of personal hostility. For this reason the Government will abstain from treating with France through M. Taigny.

Leicester.—The committee's report on the electric light undertaking gives the outstanding capital as £220,334. The revenue for the last half-year was: sale of current £14,339, increase £393; rental of stores £676, increase £76; the total revenue being £15,119. Generation of electric light cost £2,917, a decrease of £12; distribution £673, increase £93; management £735, increase £5. The total expenditure was £5 509, leaving a profit of £9 61), an increase of £366 on the corresponding period of last year. Interest on capital claims £3 697; £3 343 has been placed to the sinking fund, which leaves a net profit of £2 623. This fund, added to the profit they already had in hand, now amounts to £15,172. The Council decided six months ago that the new machinery and plant now being placed should be paid for out of the profits. When the new plant is fixed it will absorb £12,000 or £13,000 of those profits, leaving about £2 000 in hand. The department is still progressing, and the committee hope that when the new machinery now being erected is completed they will have plant sufficient to meet all demands for a very long time to come.

Maidstone.—The accounts for the electricity undertaking for the year ended March 31 show, after deducting bank charges, loan interest, and loans instalments, and provision for interest and repayments accrued to date of balance-sheet, aggregating £4,093, a profit of £466 as a net result of the year's working. For the year ended March 31, 1904, the profits before paying these charges were £2 508; last year they amounted to £4,560, a gross increase of £2,052. The gross revenue for 1904 was £6 283, and for 1905 £9,222, an increase of £2,934. The cost of earning the revenue of 1904 was £3,780, and for 1905 £4,662, an increase of £882. The interest and loan charges for 1905 exceeded 1904 by £310. The year 1904 closing with a deficit of £1,275, and the year 1905 with a surplus of £466, it follows that 1905 gained in net earning capacity the sum of £1,741. As regards the capital account, whilst the receipts were only £1,700, expenditure to the amount of £5,901 was made during the year, bringing the over-expended balances up to £5,512, which figures do not include the value of cable and meter purchases taken into stock. The Electricity Committee recommend that the formation of a reserve fund be postponed until the undertaking has been working for five years, and that the charge for energy in future for shops and dwelling-houses combined be 4½d. per unit, with a rebate of 10 per cent if over 10,000 units be consumed in the year.

Lincoln.—The electricity works revenue account for the last year shows gross profit, £3,928, carried to net revenue account. There has been paid for generation of electricity, £1,714, including coal and cartage, wages, oil, waste, repairs, and maintenance, management expenses, etc. The income from the sale of the current is: private lighting, £5,770; power, £299. 10s.; public lighting, £789. The net revenue account shows a debit balance from the last account of £906; payment to redemption of debt, £1.225; payment towards dividends on 3 per cent. redeemable stock, £1,384, and the balance at credit on March 31, 1905, was £254. The balance-sheet of the fund gives the total liabilities at £47,296, and the principal assets—land, buildings, and plant—amount to £51,332. The assets aggregate £53,979,

Digitized by Google

the balance of assets over liabilities amounting to £6,683. The accounts include particulars of the tramway accounts from the time the undertaking was taken over in July, 1904, to the end of the financial year, and there is much interesting information in the volume regarding the general district fund, the city fund, the police pension fund, and the redeemable stock and consolidated loans fund, and the education fund accounts. The aggregate balance-sheet gives the assets at £1,035 317, and the liabilities at £639,279 there being a balance of aggregate assets of £397,037, made up of the following balances: city fund, £145,998; education fund, £1 304; electricity works fund, £6 683; gasworks fund, £82,252; general district fund, £108 097; tramways fund, £3 447; waterworks fund, £49 253. The appendix contains the city accountant's report on the various Corporation undertakings. Commenting on the electricity works accounts the report states that the accounts show that the year's working has resulted in a gross profit of £3 928 (equal to 7 65 per cent. on the capital employed). From that sum has been met the sinking fund and interest charges, amounting to £2,767, leaving a net profit for the year of £1,161, an increase of £403 on last year's net profit. Nothing has as yet been set aside for depreciation, and having regard to the possible risks arising from obsolete machinery, it is very desirable, now that the funds of the undertaking permit of its being done, to begin to build up a reserve fund to meet exceptional renewals of machinery. He recommends that the amount now standing to the credit of net revenue account (£254. 6s. 1d.) be transferred to a reserve (depreciation) account.

PROVISIONAL PATENTS, 1905

SEPT. 18.

18790. Improvements in method and apparatus for producing electricity. Henry Ernest Fry, 24, John-street, Bedford-row, London.

18793. Improvements in or relating to systems of electrical distribution for lighting and other purposes. Charles Norman Staniland and Oliver Prescott Macfarlane 139, Queen Victoria-street, London.

18813. Improvements in or relating to electrolytic electricity meters. The Bastian Meter Company, Limited, and Charles Orme Bastian, Birkbeck Bank-chambers, Chancery-lane, London.

18814. Electric incandescence lamp with filament of metallic tungsten. William Phillips Thompson, 322, High Holborn, London. (Deutsche Gasglühlicht Akt.-Ges. [Auer Ges.] Germany.) (Complete specification.)

18832. Improvements in and relating to electromagnetic apparatus for producing reciprocating motion. Ferdinand Fanta, 1, Queen Victoria-street, London.

18846. Improvements in the control of electric motors. The British Thomson-Houston Company, Limited, 83 Cannon-street, London. (The General Electric Company, United States.)

18847. Improvements in prepayment electric time switches. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

18848. Improvements in prepayment meters. The British Thomson-Houston Company, Limited, 83, Cannon street, London. (The General Electric Company, United States.)

18852. A combined automatic adjusting apparatus and lubricating axle for use on trolley heads of electric cars and the like. Henry Niblett, Russell House, Albion-avenue, Bispham, Blackpool, Lancs. (Complete specification.)

SEPT. 19.

18875. An improvement in the construction of pendant, bracket, and standard fittings for gas, oil, and electric lighting. Thomas Ford and Frank Ford, Victoria Works, Emily-street, Highgate, Birmingham.

18886. Improvements in electric percussive tools. Frederick Dwight Johnson and Henry Samuel Potter, Palace-chambers, Westminster, London.

18904. Improvement connected with electric switches. George Smith, 173, Fleet-street, London.

18909. Improved method of electric welding. Adolph Frederick Rietzel, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Feb. 24 1905, being date of application in United States.) (Complete specification.)

18924. Improvements in or relating to telephonic apparatus. William Mudd Stell and Andrew George Adamson, 46, Lincoln's-inn-fields, London.

18927. Improvements relating to safety devices for use with overhead electrical conductors. Auguste Victor Millet, 7, Southampton-buildings, Chancery-lane, London.

SEPT. 20.

18943. An improved automatic device for controlling electric circuits, lamps, and the like for electric signs and the like. Charles Adams and William Chancellor, 8, Crescent-gardens, Bath.

18972. An improved electric lamp. August Bourdos and Max Lorenz, 83, Charlotte-street, London.

19007. Improvements in electrical resistances. Andrew Hilliard Atteridge and the British Submarine Boat Company, Limited, Norfolk House, Norfolk-street, London.

19015. Improvements in or relating to apparatus suitable for use in the distribution of electric current. Arthur Francis Berry, 46, Lincoln's-inn-fields, London.

19034. Improvements in wireless telegraphic apparatus. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

19035. Improvements in insulating material. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

19036. Improvements in systems of electric metering. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

SEPT. 21.

19059. Improvements in or in connection with the trolley poles of electric tramcars and like vehicles. Alfred Adams, 3, Brown-street, Market-street, Manchester.

19093. Improvements in reciprocating electric engines. Bruno Otto Wagner, Fife House, Kingston-on-Thames, London. (Date applied for under Patents Act, 1901, Sept. 22, 1904, being date of application in United States.) (Complete specification.)

19099. Improvements in and relating to automatic transmitters for electric telegraphy. Walter Judd, Angus Fraser, and Alexander Robertson Hardie, 323, High Holborn, London.

19111. Improved method of and ingredients for the manufacture of a substance suitable for electrical insulation. Charles Hess, 173, Fleet-street, London.

19116. A new or improved machine for electrically soldering metal wires, cables, hoop irons, and the like. Louis Stanislas Rolland, 31, Bedford-street, Strand, London. (Complete specification.)

19138. Improvements in and relating to dynamo-electric machines. The Allgemeine Elektricitäts-Gesellschaft, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Sept. 23, 1904, being date of application in Germany.) (Complete specification.)

SEPT. 22.

19153. Improvements in starting switches for electric motors. Thomas Edgar Weaver, 134, Claremont-road, Manchester.

19201. Constant current distributing system for utilisation of variable sources of power. Otto Bohm, 322, High Holborn, London. (Complete specification.)

19210. Improvements in protective devices for electric distribution systems. The British Thomson-Houston Company, Limited, and Edmund Basil Wedmore, 83, Cannon-street, London.

19211. Improvements in electric measuring instruments. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

SEPT. 23.

19230. Insulating supports for conductor rails of electric railways. Charles Haines and Joseph William Towill, 2, Byron-road, Harrow, Middlesex.

19259. Improvements in electric incandescent lamps and fittings therefor. Alfred William Hill and the Sir Hiram Maxim Electrical Company, Limited, 18, Southampton-buildings, Chancery-lane, London.

19264. Improvements in filaments for electric incandescent lamps and similar apparatus. The British Thomson-Houston Company, Limited, 83 Cannon-street, London. (The General Electric Company, United States.)

19285. An improved arrangement of relay and fusible conductor for electric circuits. Gino Rebora, 4, South-street, Finsbury, London. (Date applied for under Patents Act, 1901, Sept. 23, 1904, being date of application in Italy.) (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Oct. 12.

1904.

18037. Transmission and distribution of electric power. Kruyswijk.

19923. Electromagnets having polarised armatures for use in apparatus operated by alternating current. Hommel. (Date applied for under International Convention, Dec. 21, 1903.)

19979. Magnetic wheels or electromagnetic motors. Everett and Newton.

20069. Electric telegraphy. Muirhead.

20549. Dynamo-electric machines. Carolan. (General Electric Company.)

21966. Electric heat alarms. Bill and Bill.

22702. Electricity meters. Chamberlain and Hookham, Limited, and Holden.

22983. Controllers for electric circuits. British Thomson-Houston Company, Limited. (General Electric Company.)

24379. Means for use in connection with electric motors and centrifugal separators, or other apparatus driven by such motors. Scott and Williamson.

Digitized by Google

24700. Systems of electric motor control and apparatus therefor. British Thomson-Houston Company, Limited. (General Electric Company.)

24850. Instruments for detecting and measuring alternating electric currents. Fleming.

24857. Electricity meters. Capito.

24876. Electromagnetic speed-changing and reversing devices. British Thomson-Houston Company, Limited. (General Electric Company.)

25463. Brush-holders for dynamo-electric machines and electric motors. Moore and Bourne.

27707. Manufacture of an indestructible filament for gas and electric lamps for lighting and heating purposes Michaud and Delasson.

1905.

403. Electric heaters. British Thomson-Houston Company, Limited. (General Electric Company.)

1430. Method of compounding alternating-current machines Gaston Santter, Emile Harlé, and Jean Rey. (Date applied for under International Convention, Feb. 4, 1904.)

2001. Apparatus for the agitation of solutions and the like used in electro-deposition of all metals. Wood and Oakeford.

5582. Dynamo-electric machines. Lapeyrade. (Date applied for under International Convention, March 17, 1904.)

8168. Electric telegraph apparatus and devices for indicating at a distance the position of a pointer needle or the like. Usener.

8890A. Wireless telegraph transmitting apparatus. Shoemaker. (Date applied for under Patents Rule 9, April 27, 1905.)

11606. Telephone current retransmitting and reinforcing apparatus. Kingsbury. (Western Electric Company.)

NOTES.

Alexandria Exhibition.—The British manufacturers' exhibition which was to have been held in Alexandria and Cairo at the end of this year has been postponed until the latter part of 1906, in consequence of the scheme having assumed much larger dimensions than was anticipated. It is proposed that the duration of the exhibition shall be about a month, and firms who contemplate exhibiting are invited to communicate with the secretaries of the British Manufacturers' Exhibition, Alexandria, or the London agent, Mr. D. S. Murray, 11 and 12, Foster-lane, E.C.

Electro-Harmonic Society.—Arrangements have been made for the twentieth season of this society, and meetings will again be held in the King's Hall, Holborn Restaurant, the appointed dates being Oct. 20, Nov. 17, Dec. 15, Jan. 26, Feb. 23, and March 30. Of these Nov. 17 and Feb. 23 are ladies' nights. As the committee have re-engaged the King's Hall, they trust that the heavy expense involved will be justified by a further increase in the membership, and considering the agreeable evenings provided by the Electro-Harmonic, the profession should rally to the society's banner.

Electricity in Coal Mines.—At the Philosophical Hall, Leeds, Prof. G. R. Thompson delivered the inaugural lecture in connection with the Department of Mining of the University of Leeds, his subject being "Some Recent Electrical Accidents in Mines." The professor pointed out that most of the electrical accidents, so far as they affected the health or safety of the workman, had been caused by neglect of precautions which were already well known and understood. Electricity had become of increasing importance in mines, and consequently people should know its advantages and disadvantages. It was only by careful organisation and method that accidents could be guarded against.

New Publications.—"Cement and Concrete," by L. C. Sabin (London: Archibald Constable. 21s.).—"Graphic Methods of Engine Design," by A. H. Barker (the Technical Publishing Company, Limited, London and Manchester. 3s. 6d.). This treatise has a dual object, the first being to give young mechanics an explanation, based upon the author's personal experience, of easy constructions for use in the drawing office; and the second, to show the intimate relation that must necessarily exist between the science of engineering and the exact principles of theoretical mechanics. The treatise includes a graphic treatment of the balancing of engines, and should be welcomed by the embryo engineer.

The Tramways and Light Railways Association.—The *Official Circular* for September contains notices regarding proposed lectures and visits to works, rear lights on slow-moving vehicles, and the Milan Exhibition. The paper by Mr. A. L. C. Fell on "Brakes" will give the results of the exhaustive trials still proceeding on behalf of the London County Council. The reports of Messrs. Beaumont and Sellon to the Oxford Corporation on the comparative merits of motor omnibuses and electric tramcars respectively are given in full, together with a table showing how they compare with the present horse tramways. These reports appeared in our issues of the 8th and 15th ult.

Glasgow Section.—This section will inaugurate the ensuing session by holding their fourth annual dinner at the Grosvenor Restaurant, Glasgow, on the 27th inst. It is anticipated that the Lord Provost of Glasgow will honour the dinner with his presence, so it is hoped that there will be a good attendance. Tickets, 7s. 6d each (after Oct. 20, 10s. 6d. each), can be obtained from the local hon. secretary, Mr. E. G. Tidd, 68, Gordon-street, Glasgow. The dates of the general meetings, which will be held at the Institution of Engineers and Shipbuilders, are as follows: Nov. 14, Dec. 12, Jan. 9, Feb. 13, March 13, April 10, and May 8, the last-named being the annual general meeting. The annual smoking concert will be held on Feb. 3 next.

Power Supply.—Mr. Joseph Hopper, a member of the Durham County Council, addressed a public meeting the other day upon the question of a municipal power supply for the county. In the course of his address, Mr. Hopper stated that municipal enterprise had been so successful as to justify the county in attempting an electric service. He was glad to say that a court of the County Council appointed to go into the question had ascertained that, instead of public authorities being the extravagant and incapable bodies which their critics would fain make them believe, they were throughout the country conducting their businesses with 30 per cent. more efficiency and success than the companies. However this may be, we do not think it would be advisable for the County Council to start a power supply scheme even if Parliament granted the necessary power, seeing that the County of Durham Electric Supply Company already provides a service, which is being rapidly extended.

Institution of Civil Engineers.—In addition to the medals and prizes given for communications discussed at the meetings of the institution in the last session, the council have made the following awards in respect of other papers dealt with in 1904 1905: a George Stephenson medal to Captain H. R. Sankey, R.E. (retired), London; a Watt medal to Dr. C. Chree, F.R.S, Richmond; Telford premiums to Messrs. W. E. W. Millington (Oldham), C. E. Stromeyer (Manchester), C. W. Hill (London), F. C. Lea (London), W. B. Cole (London), W. C. Popplewell, M.Sc. (Stockport), E. H. Rigby, B.Sc. (Tientsin), and W. O. Leitch, jun. (Tientsin). For students' papers the awards are: Miller prizes to Messrs. A. B. Potts (Macclesfield), W. M. Hayman (Glasgow), R. E. Bury (Calcutta), T. Lees, jun. (Winnipeg), T. L. Matthews (London), P. J. Risdon (London), F. E Tudor (Stevenage). The inaugural address for the ensuing session will be delivered by the president, Sir Alexander Binnie, on the 7th prox., when the awards will be presented.

New Post Office Power Station.—The half-completed chimney shaft on the south side of the Thames, near Blackfriars Bridge, marks the site of the new Post Office power station, which is to do the work at present performed by the machinery at St. Martin's-le-Grand. The new building, which is to be completed in about 18 months' time, will contain machinery of 2,500 h.p. Electric power will be provided for pneumatic tube work, lighting, lifts, fans for ventilation, for the work of stamping and obliterating machines, and for charging batteries for telegraph and telephone work. At present this power is obtained from the plant in use at St. Martin's and from the power station at Mount-pleasant, but the Post Office authorities consider that the larger engines and boilers in the St. Martin's building are a source of considerable risk and inconvenience. In addition, the present position does not admit of the extension which the immense amount of work devolving on the Post Office machinery necessitates. All necessary machinery will be duplicated, so as to obviate any stoppage. The whole of the work is to be done by English firms.

Municipal Electrical Association.—The council of this association paid its second visit to Barrow on Saturday. The president, Mr. E. A. Newington, of Edinburgh, was

Digitized by Google

unfortunately unable to be present, but there were in attendance Mr. S. E. Fedden, Sheffield, vice-president; Messrs. J. H. Rider (London), J. F. C. Snell (Sunderland), and T. P. Wilmhurst (Derby), past-presidents; and the following members of the council: Messrs. J. Christie, Brighton; S. L. Pearce, Manchester; C. E. E. Shawfield, Wolverhampton; Councillor Sinclair, Swansea; Alderman J. P. Smith, Barrow; C. D. Taite, Salford; H. Talbot, Nottingham; G. Wilkinson, Harrogate; Alderman G. Pearson, hon. solicitor, Bristol; J. E Edgcome, hon. secretary, Kingston-on-Thames; and the secretary, C. McArthur Butler. Alderman Smith escorted the council, in the morning, through Messrs. Vickers, Sons, and Maxim's works, where they were greatly interested in the large amount of electrically-driven plant in use. The council then repaired to the town hall, where the business was transacted. Later the party were entertained to luncheon by the mayor, when complimentary speeches were exchaned.

Armatures.—A patent has been granted to Mr. W. B. Sayers for a type of tooth-cored armature, of which a description appears in the *Official Patents Journal* As shown, alternate teeth, 1, are made separate from the body of the core, which is formed with projections or teeth, 3. Channels, 4, are made in the core to receive the separate teeth. Fig 1 shows one method of securing the teeth, the stampings on each side of the ventilating space, 10, being kept in place by brass pieces, 11, 13, with a wedge, 14,

FIG.1.

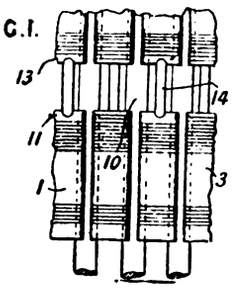

FIG.2.

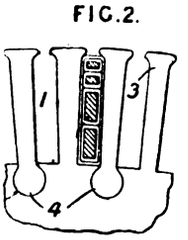

between them. To facilitate insertion, each stamping may be slightly bent along its centre line and flattened when pressed into position. When all the teeth are separate from the core, the alternate channels, 4, for their reception are made at different depths in the core, alternate teeth being made of correspondingly varying lengths.

Electric Resistances.—A patent for electric resistances has been obtained in this country by the Chemische Fabrik Prometheus Company of Frankfort, and a description of same appears in the *Official Patents Journal* Silicon, the carbides of silicon, boron, and other elements, and similar substances are converted from the powdered condition into coherent resistance bodies at a temperature below their fusing point, preferably by heating them in an electric resistance furnace. The mechanical strength of the product may be increased by dipping it in difficultly fusible enamel and reheating, or by adding to the raw materials a flux, such as boracic acid, felspar, or borax. The first-named flux is preferred, as it increases the conductivity of the product. Instead of crystalline carbide, the mixture of raw materials used in the manufacture of the carbide, or, in the case of silicon carbide, the amorphous carborundum obtained as a by-product, may be used. The resistance bodies may be applied to the construction of resistances for arc lamps, preliminary heaters for Nernst lamps, filaments of incandescent lamps used for heating rather than lighting, and of regulating resistances. In the last-named case the contact springs may slide on a curved or straight bar of the substance.

Labour Difficulties.—The workmen having decided not to accept the terms offered by the leading Berlin firms, Messrs. Siemens und Halske and the Allgemeine Elektricitätsgesellschaft, these firms proceeded on Saturday from a partial to a general lock-out involving 33,000 people. The representatives of the workmen appealed to the standing Court of Arbitration, which at once invited the employers to take the same step. The employers declined to submit their case to the court as such, but intimated their willingness to hold a conference with the leaders of the men under the chairmanship of the president of the Arbitration Court. The conference met on Tuesday, and after a very long sitting adjourned till the next day, when the proceedings proved abortive. Later advices put the number of people out of employment at about 40,000, as declarations of solidarity with the workmen and promises of financial support have been received from various organisations in other trades. With the aid of the officials of the company and of numbers of "strike-breakers," the Berliner Elektriziltätswerke have hitherto been able to continue with comparative regularity their supply of electric power and light for the city, but the tramway service had to be curtailed for a few days. It is understood that a further effort has been initiated by the burgomaster to reopen negotiations between the employers and the workmen.

Motor Control.—A patent has been obtained by Mr. J. Bentley, of Manchester, relating to a motor with speed-control arrangements, having two sets of field magnets and two armature cores provided with a common armature

FIG.1.

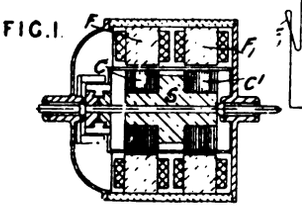

FIG.2.

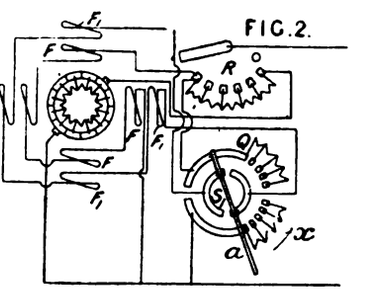


winding, of which a description appears in the *Official Patents Journal*. The two sets of field magnets, F F_1, and armature cores, C C_1, mounted on a brass hub, S, form two separate magnetic circuits. The connections between the motor and the starting and regulating switches, R_1 S_1, are shown in the second diagram. The current in the field coils, F, remains constant, while the speed of the motor is increased from its lowest to its highest value, the current in the field coils, F^1, being varied by rotating the arm of the switch, S_1, in the direction of the arrow, *x*, from its initial position, *a*, to its final position, Q. When the arm is in the position *a*, the current flows in the same direction in the field windings, F F_1, the rotation of the arm first inserting resistance, then reversing the direction of the current, and finally cutting out resistance in the circuit of the winding, F_1.

Wireless Telegraphy.—The jury of award at the Liége Exhibition has given the highest award—the Grand Prix—to Marconi's Wireless Telegraph Company, Limited, for their exhibit of wireless telegraph apparatus. Wireless telegraph apparatus has for some time been installed on board the day steamers on the Flushing-Queenborough route, and will in a short time be installed on board all the night boats. The usual Continental rates for telegrams are charged. The Board of Trade have received from the Canadian Government a copy of the Wireless Telegraphy Act, 1905, which was assented to on July 20, 1905, and provides for the regulation of wireless telegraphy in Canada. By Section 3 of the Act it is provided that "no person shall establish any wireless telegraph station, or instal or work any apparatus for wireless telegraphy, in

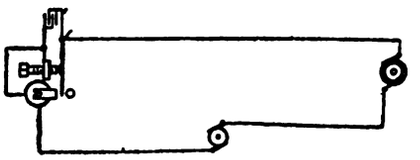
Digitized by Google

any place or on board any ship registered in Canada, except under and in accordance with a license granted in that behalf by the Minister of Marine and Fisheries with the consent of the Governor in Council." It is also laid down in the Act that where an applicant for a license proves that the sole object of obtaining a license is for the purpose of conducting experiments in wireless telegraphy, a license for that purpose shall be granted, subject to such special terms, conditions, and restrictions as the Minister thinks proper. It is reported that a somewhat remarkable extension of the distance at which steamers fitted with wireless telegraphy can communicate with the shore was made last week, when the "Lucania" on her outward voyage to New York got into communication with Nantucket lightship 803 miles to the east of that point.

Resuscitation from Electric Shock. — At the recent convention of the Ohio Electric Light Association an interesting paper on this subject was presented by Mr. E. E. Noble, of which an abstract appears in the *Electrical World* of New York. The paper gives an account of some researches of two Cleveland physicians as to the probable cause of death from electric shock. The conclusions are that death from the passage of heavy current through the body is due either to temporary stoppage of the heart or contraction of the muscular fibres of the heart, whose function is to force the blood to the general circulating system and the lungs. There is also a fall of arterial blood pressure. The physicians claim that their experiments showed that unless a relatively large part of the current passing through the body traverses the heart, the shock would not necessarily prove fatal, and that by the prompt application of artificial respiration a patient may be restored. It was stated that an examination of the blood showed that electric currents "up to 2,300 volts" cause no chemical or other changes in the blood itself, nor any change in the tissue of the brain or spinal cord or other nerve structures. Our contemporary notes that this is contrary to the evidence of autopses of criminals executed by the electric current, where the presence of numerous lesions were noted. The physicians recommend a method of resuscitation which is already well known to electricians, and the author of the paper suggests the wearing by those exposed to high voltages of a light metallic gauze jacket next to the skin, or a system of metallic bracelets worn around the upper arms and connected by means of flexible conductors, and a belt of some similar material worn around the waist or some part of the body below the heart.

Electricity for Motive Power.—Colonel Crompton succeeded in a rather difficult task at the Olympia Exhibition on Tuesday evening, when he made a technical subject, though not treated in that spirit, highly interesting to a large public meeting. The colonel emphasised the great interest attending the larger use of electric motors, as an increased load factor meant a cheapening in the supply of electricity generally. Current for lighting was necessarily dear while electricity was confined to that field, but there was no reason why electricity for lighting during daylight hours should not be as cheap as for power, provided that the demand did not encroach upon the hours of maximum demand for lighting, which only represented a small proportion of the whole. He considered that a two-rate meter would be the best method of promoting the use of electricity. Many authorities had already adopted a special rate for power purposes, but the colonel suggested that there ought to be a special rate for using current in the daytime. He waxed quite enthusiastic upon the possibilities of electricity in the household, and hoped that at no distant date the hand labour of the "general" would be replaced by electrical energy. Motors should be used to operate dish and bottle washing machinery, plate cleaning, meat and sausage chopping, dough kneading, and domestic laundry appliances. In addition to this he saw many opportunities for electric power in commercial fields where it is not at present employed to any extent, such as metal working, cutting and polishing jewellery, bookbinding, and cabinet making; while the use of motors to compress air would enable everyone to have a cold-storage room in his own house. The colonel touched upon the scheme of the Administrative County of London Company, stating that it was designed solely to promote the general use of electricity for power purposes. The lecture was evidently appreciated, and should assist in bringing home to the public the fact that by the general adoption of electrical power it would be possible to give a supply at cheaper rates.

Alternating-Current Rectifier. — An interesting form of alternating-current rectifier has been patented in the United States by Mr. J. H. Robertson, a description of the same appearing in the *Electrical World* of New York. While the operation of the device depends upon the opening and closing of a circuit at the desired instants according to the relative signs of the alternating E.M.F., no synchronous motor with revolving commutator or equivalent equipment is employed. The position of a vibratory contact maker is determined by the polarity of an electromagnet whose coil is subjected to the alternating E.M.F. The contact maker, which is mechanically connected to the polarised armature of a permanent magnet,

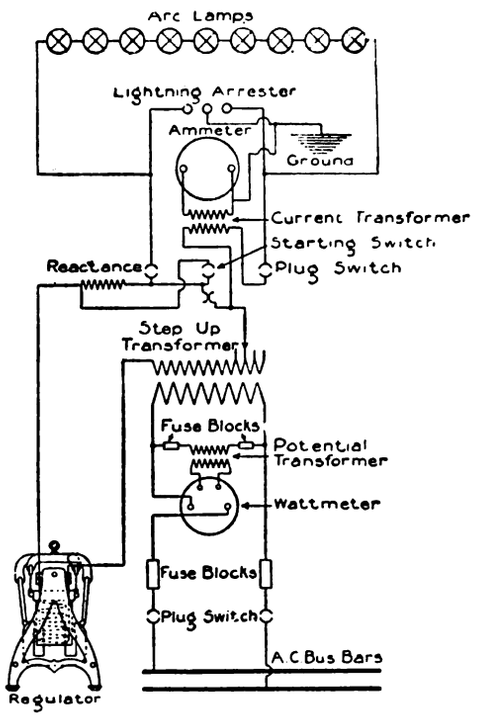


is normally held closed. During operation, the polarised armature is acted upon not only by the permanent magnet, but also by the electromagnet. When the polarities of these two magnets are of the same sign, the contacts are held tightly together. When, however, the electromagnet reverses its sign and becomes of sufficient strength, the polarised armature is repelled, and the circuit broken. Thus the circuit is closed when the E.M.F. is of one sign, and is open during the major portion of the time when the E.M.F. is of the opposite sign, so that the resultant current, although pulsating in value, is practically unidirectional. It is evident that a combination of two rectifiers with relatively reversed electromagnets will allow equal values of currents to be taken from the source of supply both when the E.M.F. is negative and when it is positive, so that the load on the supply system will be balanced with reference to the successive alternations. The device, which is illustrated in the accompanying diagram, is simple, of few parts, and quite compact. For charging the storage batteries of automobiles at places where only alternating current is available, the magnetic rectifier possesses the advantageous feature of being transportable by the automobile itself.

Series Alternating-Current System of Arc Lighting.—A system of series arc lighting circuits which may be readily operated upon a constant-potential supply has recently been developed by the Fort Wayne Electric Company. Its special advantages are its simplicity, the slight attention it requires, and its flexibility, permitting it to operate in parallel with an incandescent system, if desired. The system consists of a regulator for maintaining a constant current, a specially designed high-tension switchboard, a constant-potential transformer, and a series of arc lamps, in addition to which both sides of the line are

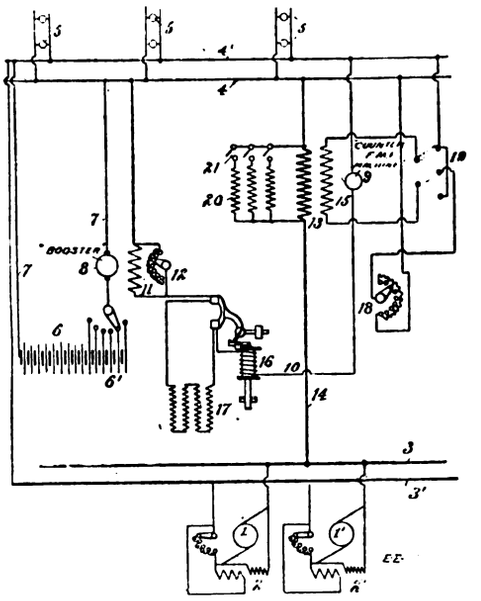
Digitized by Google

equipped with a lightning arrester peculiarly adapted to circuits of this nature. The accompanying diagram, which we reproduce from the *Western Electrician* of Chicago, shows the scheme of connections. The operation of the regulator designed for this system depends upon the automatic introduction of impedance into the lamp circuit whenever any decrease in the resistance of the latter would tend to cause an excessive current to flow therein. This impedance is introduced by the combined movements of a laminated iron core and impedance coil into such a position as to cause a greater magnetic flux to be cut by the current in the coils. This increase in the amount of flux cut by the line current produces a choking effect, reducing the latter to its normal value. Reference to the diagram will show the peculiar design of the switchboard, by means of which the system may be quickly started from the switchboard without paying any attention to the regulator and without causing any excessive rush of current through either the regulator or the lamps in so doing. The ability to thus start without any disturbance upon the line is one of the greatest advantages of the system. The starting switch, which is located in



the centre of the panel, should always be closed last, the closing being effected in three stages. The constant-potential transformer may step up or step down the 'bus-bar voltage, or may in some cases maintain the same voltage upon both primary and secondary in cases where it is introduced for insulation purposes only. The secondary of this transformer is provided in a number of taps, by the use of which the output of the station may be varied as more arc lamps are needed upon the circuit, maintaining at all times practically full-load efficiency and power factor. The system has been designed for either 60 or 140 cycles, and has been found to operate with complete satisfaction at either frequency, although the former is considered preferable.

Controller for Storage-Battery Boosters.—A patent has recently been granted in the United States to Mr. A. S. Hubbard, and assigned by him to the Gould Storage Battery Company, of New York, for an improved method of regulating the control of the booster in systems embodying the use of a storage battery and booster. In the accompanying diagram, which we reproduce from the *Western Electrician* of Chicago, the generators are indicated as connected to 'bus bars, 3 3', from which the current is taken to supply mains for a lighting or power circuit. The storage battery is provided with regulating cells, 6', and is connected across the mains in a circuit, 7, which indicates the armature, 8, of the booster. The booster armature is driven at the desired speed by suitable connection from any convenient source of power. The booster field, 11, is energised by the difference between the different potentials, which act oppositely thereon. The booster field coils are connected in a circuit of a counter E M F. generator, 9, the armature of which is connected across the mains, 4 4', so that the field winding is energised by a current due to the difference between the voltage on the mains and that of the counter E.M.F. machine. The field of the counter E M F. generator is provided with a coil, 13, which is so connected as to be traversed by the current supplied by the generators, being included, for example, in the connection, 14, between a dynamo 'bus bar, 3, and the corresponding side, 4, of the mains or work circuit. The effect of this field may be varied by means of any suitable devices, such as by shunts and their switches. Other field-regulating devices for the machine, 9, may be provided—as, for instance, a coil, 15, in a circuit connected, as shown, in parallel with the mains, so that the system may readily be adjusted for different generator loads by manipulating rheostat, 18, and pole changer, 19, included in the circuit.

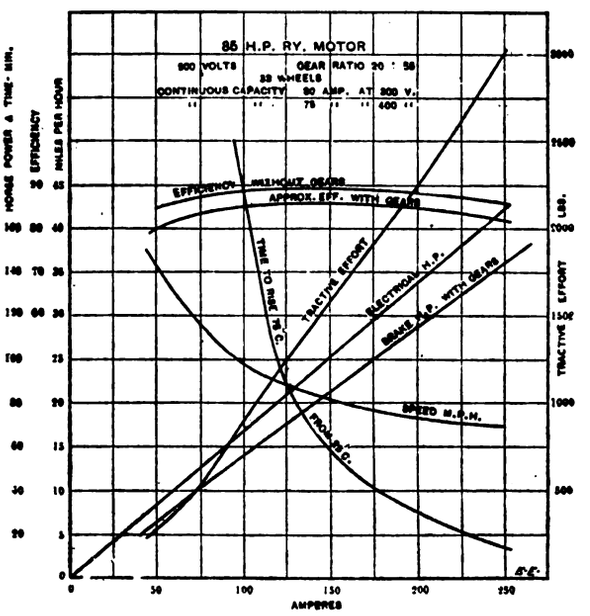


In the operation of the system it will be seen that the field winding, 11, is energised by a voltage equal to the difference between the potential difference of the mains, 4, 4', and that of the machine, 9. In order that the field winding, 12, may be protected from abnormal increase of current, which obviously may occur through any derangement of the system that would materially affect or cut out either of the sources of potential difference affecting this circuit, there are provided means for increasing the resistance of the booster field circuit which act automatically when the electrical condition of the booster field winding circuit permits an abnormal increase of current. This is effected, preferably, by the resistance, 17, in series with the field winding, 11, and the circuit breaker, 16, connected in a short circuit around the resistance. Normally, as shown, the current to the booster field winding passes through the circuit breaker and the actuating coil. When however, the current increases to the desired limit the circuit breaker, 16, opens and the resistance, 17, acts to reduce it to a safe quantity. It will be observed that this insertion of resistance, in addition to preventing any actual burning out of the field winding, 11, has the advantage of preventing dangerous derangements of the

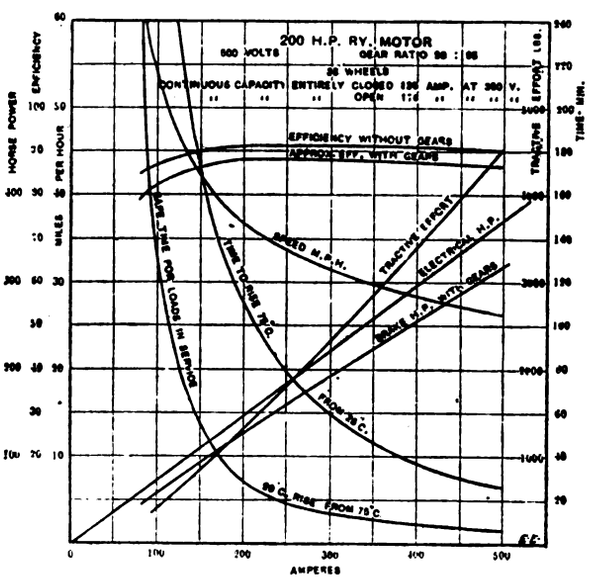
Digitized by Google

system due to abnormal changes of booster voltage. In the specific regulating apparatus shown the resistance also protects the counter E.M.F. generator, 9.

New Westinghouse Railway Motor. — The American Westinghouse Company have introduced a new line of motors for heavy traction, the sizes ranging from 75 h.p. to 200 h.p. Among the features of particular interest which characterise these motors may be mentioned the diagonally divided field frame, which makes every part accessible; the gear case, supported entirely at the ends, so as to avoid the side strains which have been the source of so much trouble; housings for armature bearings clamped between the two halves of the frame; generously proportioned bearings with a system of lubrication claimed to be the most effective yet devised; armature and commutator assembled upon a single spider; bar-wound armature with split coils; commutators with many bars; low current density in the brushes; bolted-in laminated poles; sealed field coils wound with strap; excellent commutation; high efficiency; low operating temperature and great mechanical strength. Limitations are naturally placed on the size and construction of a motor by the amount of available space on the truck of the car; therefore, the frame of square cross-section was adopted as



utilising this space most advantageously. By lifting off the upper half of the field casting the armature may be removed from the frame without taking the motor from the truck; or the motor may be removed from the truck by simply taking off the gear case and axle caps. Housings for the armature bearings are circular in form and are turned slightly larger in diameter than their seats in the frames, so that when clamped in place all the advantages of a press fit are obtained. The armature bearings are made of solid phosphor-bronze bushings finished all over, with a $\frac{3}{32}$in. lining of babbitt metal. If from neglect the bearing should become so hot as to melt the babbitt, the armature would be supported on the brass shell, and would not strike the poles. Both oil and waste lubrication are provided. The amount of oil in the reservoirs may be gauged so that it may be kept at the proper level for economical service. It is stated that with intelligent care these bearings will run 100,000 to 150,000 miles. The axle bearings are similar in construction to those of the commutator, except that split bushings are used. Here also lubrication is by means of oil and waste, the oil being supplied from below. This is the same method as that which has given such universal satisfaction in steam railway service. All bearings have generous dimensions, and the large surfaces readily dissipate the frictional heat and ensure cool running. The laminated pole-pieces are bolted to the top, bottom, and sides of the motor frame, which, being almost square in cross-section, permits the use of flat field coils. These coils are wound of copper strap insulated between turns with treated asbestos ribbon, and then carefully taped and given repeated dippings in specially prepared insulating compounds and varnishes, which makes them moisture-repelling and able to stand internal heat. The shaft is forced into the finished armature and keyed thereto, and may be removed, should necessity arise, without disturbing the windings or commutator. The armature coils are strap-wound, and made in two parts. As the top coils are more liable to injury, this design makes it possible to remove the damaged part without disturbing any other part of the winding. The coils are liberally insulated with mica, and sealed and further insulated by dipping in varnishes which are oil-proof and moisture-repelling. On each end the armature slots are made deeper and wider, thereby providing space for mica cells, which greatly reinforce the insulation at these points. As a further protection, fibre strips are taped to the upper sides of the top coils. A bell-shaped flange at the pinion end and a cylindrical flange on the commutator end form rigid supports for the windings. Countersunk bands of steel wire on the core hold the



coils firm and secure. Openings through the spider and core allow a free passage of air, which is thrown forcibly against the field coils, thus maintaining a low temperature throughout the motor. The brush-holders are of the sliding type, with springs of phosphor-bronze held in a harness which definitely fixes the radius of action of the spring tip, and is so constructed as to practically eliminate friction between turns, which gives a very uniform pressure upon the brush over a considerable range without requiring adjustment. The tension of the spring may be adjusted without removing the holder from the motor. The brush-holder proper is bolted to an insulated guide, and may be removed without disturbing the insulation or connections. Leads of frame-proof flexible rubber-covered cable are brought out at the front of the motor over the commutator through insulator bushings. Access to the brushes and brush-holders is provided through a large opening in the frame over the commutator, which extends well down the side, making inspection easy from the pit. A hole in the rear end bell and an opening under the commutator facilitate inspection of the clearance between the armature and field poles. The accompanying diagrams illustrate the characteristics of a 85-h.p. and a 200-h.p. motor respectively.

ALTERNATE-CURRENT MACHINERY AT OLYMPIA.

BY P. R. FRIEDLAENDER.

The exhibition is rather disappointing as regards alternating machinery, for, in spite of the fact that during the last few years more advance has been made in this branch than perhaps in any other, only about a dozen firms exhibit this class of machinery, and in most cases these exhibits comprise quite small examples only.

Since the only alternating supply available at the exhibition is a single-phase one, all the alternate-current driving is done by single-phase induction motors, and several of Messrs. Langdon-Davies's well-known machines are to be seen at work on the stands of different exhibitors as well as on the company's own stand (No. 30). These motors are usually of the short-circuited rotor type, and are started by means of a simple throw-over switch, which on the "starting" side puts the starting stator winding direct across the supply mains, and the "running" stator winding in series with a non-inductive resistance also across the mains. This arrangement, in combination with the higher inductance of the "starting" winding, gives the necessary phase difference for starting purposes without the use of choking coils or condensers. On the "running" side of the starting switch (to which the handle may be moved as soon as approximately full speed is reached), the resistance in

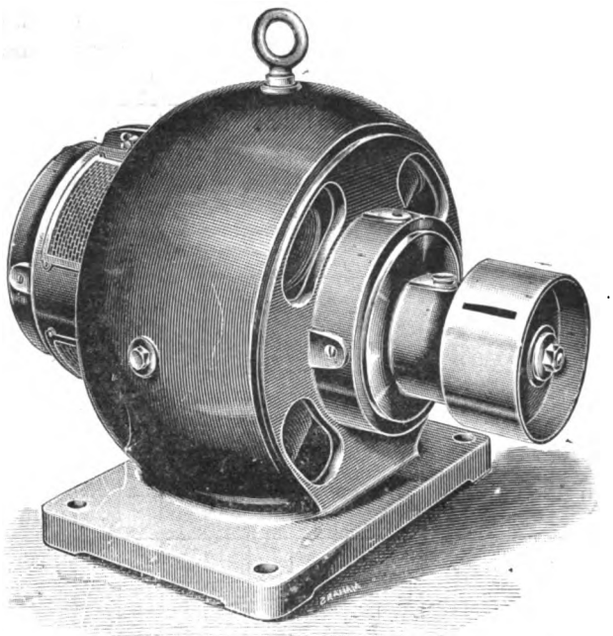

FIG. 1.—Langdon-Davies Single-Phase Motor.

the running winding is cut out, and at the same time the starting winding is entirely disconnected, so that the running winding alone remains in use, and is connected directly across the mains. This method of starting single-phase induction motors by the use of a resistance alone is adopted by several other firms, including the Fuller-Wenström Company and the Brush Electrical Engineering Company, and, in combination with a loose pulley, gives perfectly satisfactory results. Other makers—*e.g.*, Messrs. Crompton and Co. and Messrs. Siemens Bros.—employ a choking coil in the starting winding of the stator as an aid in producing the necessary phase displacement.

In place of the usual fast-and-loose pulley arrangement, Messrs. Langdon-Davies have recently brought out a neat friction clutch (Fig. 1), worked by hand by means of a lever on the bearing, whilst the Fuller-Wenström Company have a very simple automatic contrivance for the same purpose. This occupies no more space than the ordinary single pulley. It consists of a pulley keyed to the shaft, and against the rim of which four iron segments are held by spring pressure. This pulley revolves within a second pulley, which is free on the spindle, and on which the belt runs. As soon as full speed is reached the four segments fly outwards under the centrifugal action, and automatically clamp the two pulleys together by friction.

The Crypto Electrical Company show a number of small single-phase motors from ⅛ h.p. to 2 h.p., as well as small alternators and motor-generator sets. The motors are of the squirrel-cage type, and starting is accomplished by closing the main switch and pressing a button for a few seconds. The button puts the starting winding into circuit, and this is cut out again by releasing the button as soon as full speed is reached.

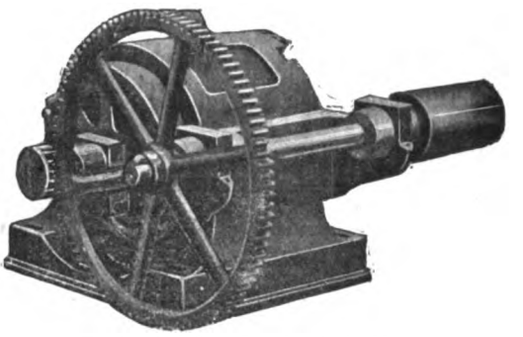

FIG. 2.—Back Gear, Langdon-Davies Moto

When motors with "wound" or slip-ring rotors are employed, as is the case whenever any considerable starting torque is required from either single or polyphase motors, the three-phase winding with three slip-rings seems practically always to be adopted, whatever the number of phases of the stator supply may be. Some makers—*e.g.*, Messrs. Vickers, Sons, and Maxim, the General Electric Company, the Lancashire Dynamo Company, etc.—place the slip-rings outside the bearing, with the connections to the rotor passing through the hollow spindle (see Fig. 3). This makes a very compact motor, although when placed *inside* the bearing (as in the motors made by the Brush Electrical Engineering Company, Messrs. Crompton and Co., the Phœnix Dynamo Company, and Messrs. Siemens Bros.) the rings and brush gear are better protected, and this is of some

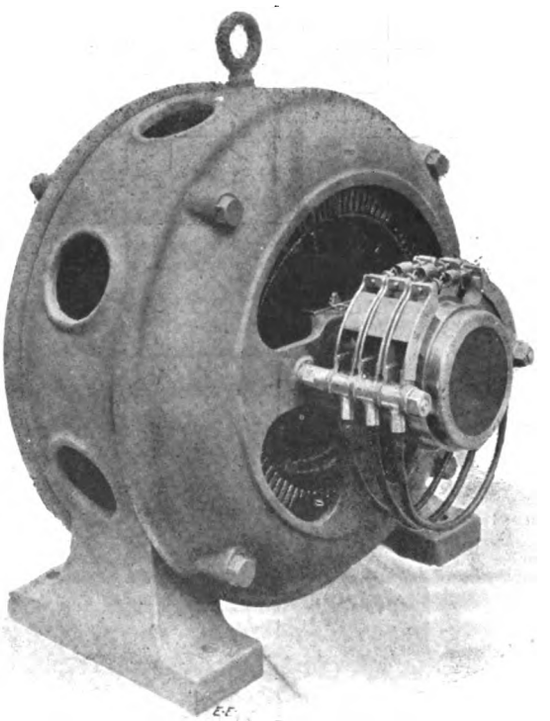

FIG. 3.—Three-Phase Motor made by Messrs. Vickers, Sons, and Maxim.

importance at starting, when considerable voltages sometimes exist between the rings. The starting and speed-regulating switches and resistances employed with these "wound" rotors are very varied in form, liquid resistances being occasionally used, though they are more commonly made up of wire spirals or cast grids.

Messrs Siemens Bros. have recently combined a "no-voltage" release with their rotor starting resistances, and samples of these are exhibited on their stand (Nos. 99 and 100). When the main (stator) switch of an induction motor is opened, or when the motor stops, due to accidental interruption of the supply, the rotor comes to rest with all its resistance cut out and the rings on short-

Digitized by Google

circuit, so that if the main switch is once more closed an excessive starting current will be taken, and will probably cause the blowing of the fuses. This difficulty also occurs in the case of direct-current motors, and has been met there by the employment of automatic "no-voltage" release switches, but these have hitherto seldom been provided for induction motors. In Messrs. Siemens's arrangement the three-armed rotor switch is held in the "on" or short circuiting position against the action of a strong spring by means of a trigger controlled by a small three-limbed, three-phase electromagnet. This is excited by the rotor currents, and as soon as these currents fall below a certain value the magnet lets go and the switch flies back to the "off" position, at which the rings are on open circuit and ready for starting up again safely.

Messrs. Siemens also show a three-phase induction motor with a "wound" rotor, but without slip-rings (Fig. 4). The cutting out of the resistances and the final short-circuiting of the rotor windings is accomplished by means of a three-armed switch, rotating with the rotor and actuated whilst the machine is in motion by means of a sleeve and hand-wheel at the end of the spindle. The resistances in this case are in the form of metal grids, securely mounted inside the rotor core. This arrangement makes a compact self-contained motor, and also allows the rotor to be really short-circuited without the intervention of the usual brush contacts and leads between the motor and its starting switch, which often cause an appreciable reduction in efficiency.

FIG. 4.—Siemens Three-Phase Motor.

As regards mechanical design, the various makes of motors exhibited have a great deal in common. They are usually of the protected type, with the end covers carrying the bearings and attached to the ventilated cast-iron frame which supports the stator discs. The bearings are self-oiling, and, for the small sizes, ball bearings are occasionally used The induction motors made by the Lancashire Dynamo Company are provided with a useful bearing centre adjustment in the end covers. These end covers are made without registers, and the clamping bolts are an easy fit in the bolt holes, so that the exact position of the end covers (and rotor) relatively to the stator frame and discs is determined by three conical ended screws bearing on conical facings on the stator frame. When the motor bearings wear, therefore, it is only necessary to slacken the bolts, adjust the three screws until the air-gap is again uniform all round, and tighten up the bolts once more. As the rotor surface as well as the stator bore are ground smooth, it is an easy matter to decide when the air-gap is uniform by means of feelers inserted between rotor and stator.

Practically all the motors exhibited have half-closed slots on both rotor and stator. The winding is threaded through turn by turn from the end, and the tops of the slots are then closed by strips of fibre or presspahn, all binding bands being omitted.

Of the much-discussed single-phase series and repulsion type of traction motor the exhibition hardly shows a trace. The nearest approach to these is to be seen on Messrs. Crompton and Co.'s and on the Lahmeyer Electrical Company's stands. Messrs. Crompton show a 10-h.p. special type of repulsion motor (Crompton-Goldschmidt patent) fitted with four slip-rings, each of which is split into a number of separate segments not unlike a rudimentary commutator. The Lahmeyer Electrical Company show a single-phase reversible hoist motor of the Schüler "mixed action" type. The motor is fitted with a commutator (with short-circuited brushes) at one end and three slip-rings at the other end, whilst the stator is fitted with three single-phase windings One of these windings is in use for both directions of rotation, aided by one of the remaining windings for clockwise rotation, and by the other for counter clockwise rotation. When starting up, the slip-rings are connected through a high resistance, as in the case of an ordinary induction motor, and the greater part of the starting action depends on the commutator, the motor acting mainly as a repulsion motor. As the speed increases, and the resistance between the rotor rings is gradually reduced, the commutator takes less and less current and the rings more and more current until at full speed the commutator is practically idle, and the motor runs as an ordinary single-phase induction motor. These machines, however, are not what is usually called a single-phase traction motor, and although several English firms are undoubtedly making the latter type, if not commercially at least experimentally, it is not to be seen at the exhibition.

The Bat Electrical Company show two of their "permutators" for converting alternating current into direct current. These machines, which are being put on the market in sizes up to 200 kw., are in some respects similar to rotary converters, but the armature and commutator are fixed whilst the magnets and brush gear rotate. It is claimed that they are easily self-starting on the alternate-current side, and that their vertical arrangement reduces the necessary floor space to a minimum.

As examples of the larger sizes of alternate-current machinery, reference may be made to Messrs. Lahmeyer's 520 b.h.p., 10,000-volt, 50 ~, three-phase synchronous motor on stands No. 94 and 105. This is running during the exhibition as a three-phase generator at half speed, giving 2,000 volts at 25 ~ for use (after transformation to 220 volts) in driving the complete haulage gear shown in operation by this company. The haulage gear motor is a totally enclosed three-phase induction motor for 100 b.h.p. at 137 r.p.m., and is fitted with a "wound" rotor arranged for two phases. The speed of the motor is regulated within wide limits by means of resistances inserted in the rotor circuits. There are 15 resistance steps in each phase, so as to permit smooth starting and stopping, and the whole operation of the plant is carried out by a single controller lever. Moving the lever backward or forward stops or starts the motor, whilst sideways motion reverses its direction of rotation. The controller contacts work under oil, and the resistances are of metal immersed in oil and specially cooled by oil circulated by a small pump driven from the motor spindle.

Alternators are practically unrepresented, although one or two motor-alternators are to be seen—*e.g.*, on the Phœnix Dynamo Company's stands, Nos. 117 and 126. Messrs. Crompton and Co. show a 50-h.p., three-phase, slip-ring, induction motor used during the exhibition as a 30-h.p. single-phase motor driving a direct-current generator for arc lighting purposes. The Brush Electrical Engineering Company's exhibit includes one of the largest transformers yet made in this country. It is a three-phase oil-cooled transformer for an output of 500 kw., the primary being wound for 5,000 volts and the secondary for 500. The core has three straight vertical limbs of approximately circular section, connected at the top and the bottom by straight yokes of rectangular section, and it is arranged with oil-circulating passages throughout. The windings are divided into a number of well insulated sections, and alternate primary and secondary sections are placed side by side along each limb.

In conclusion, it must be admitted that the exhibition hardly gives an adequate idea, either as to amount or size, of the alternate-current machinery which British manufacturers are capable of turning out at the present time.

SOME NEW DESIGNS IN ELECTRIC LIGHT FITTINGS AT OLYMPIA.

[BY OUR SPECIAL ARTIST.]

(Continued from page 446.)

The stand of the London Electrical Fittings Company, Limited, of 7A, Soho-square, W., is well worth seeing for the large number of beautiful fittings which they have on view and wired. Like with most other fittings makers, special prominence is given here to the Adams style, as

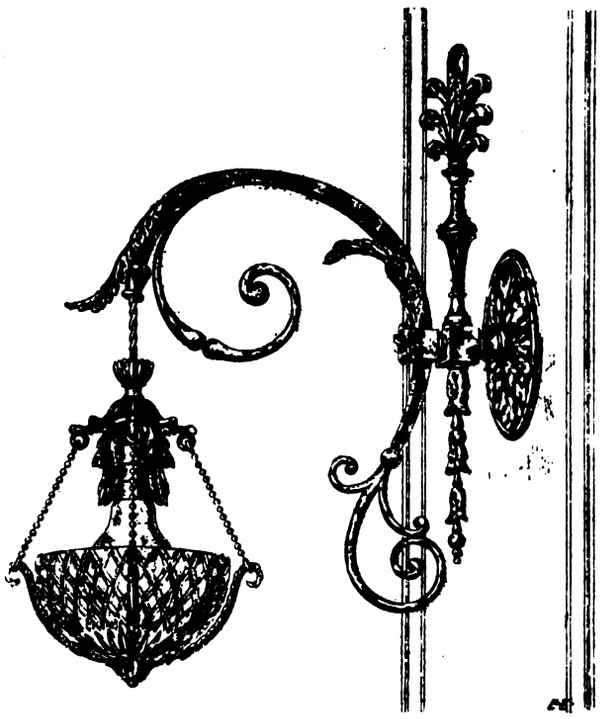

FIG. 10.

well as to the more modern fittings with graceful lines. A particularly charming bracket in the Adams style is shown in Fig. 10. This fitting is made in either dead gold or gilt, and the cut-glass bowl serves to reflect some of the light upwards. The whole bracket only projects 9in. to the holder, and is eminently suited for mounting on or between watered silk or other similar styles of panels now in vogue. Another bracket, which we illustrate in Fig. 11, is neat and pleasing, being specially suited for boudoirs, smoking-

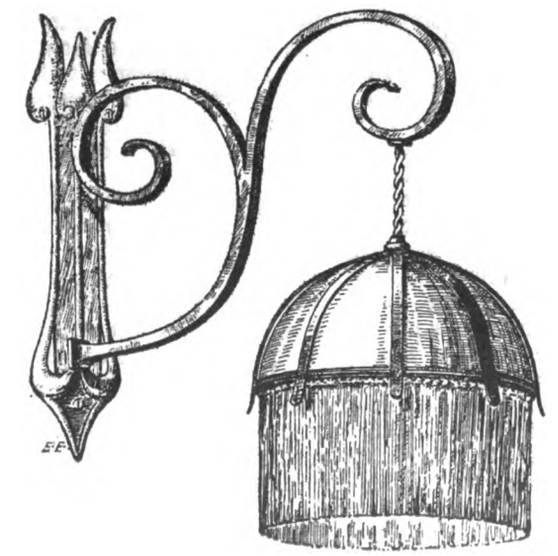

FIG. 11.

rooms, etc. The metal work can be finished in polished brass or oxidised silver. The projection to holder is only 8in.

Candle fittings are by no means relegated to the past. They naturally assume the Louis or Adams styles, and a particularly pretty one in the latter style is shown in Fig. 12 for mounting between two panels. This is made in dead gold and gilt finished. The company show a large number of lanterns for which the present farmhouse revival in architecture has created a demand. Space, unfortunately,

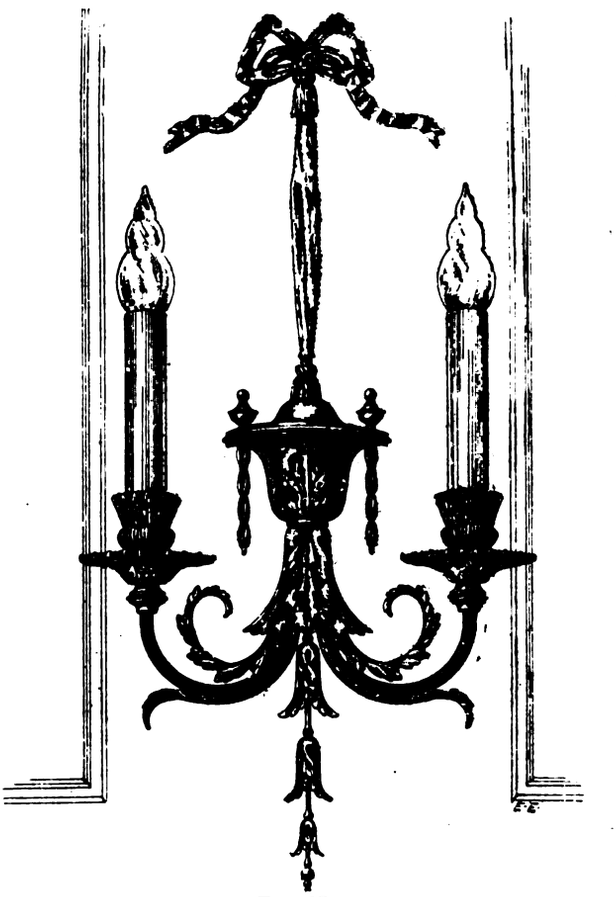

FIG. 12.

only permits us to show one design, which is made either in antique bronze or oxidised silver. As will be observed from the illustrations, the ornaments and glass have a neat floral design. All these illustrations are to scale, Fig. 13

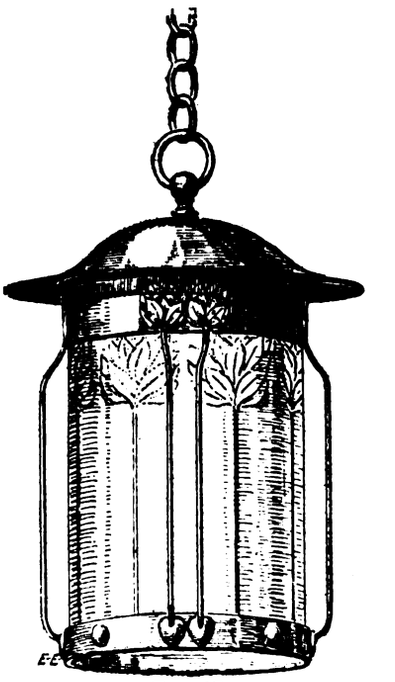

FIG. 13.

being one-sixth the full size, and the remainder quarter scale.

The exhibit of electric light fittings at the stand of the General Electric Company, Limited, of 71, Queen Victoria-street, E.C., gives no idea of the size of their showrooms and the business they do in this line. This is, no doubt,

FIG. 14.

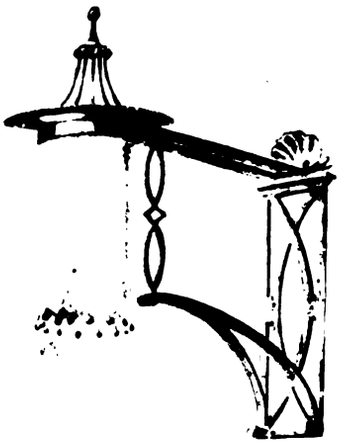

FIG. 18.

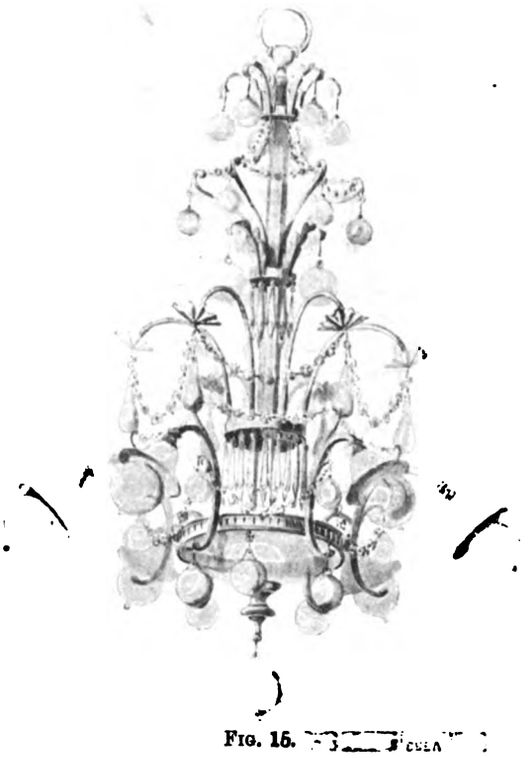

FIG. 15.

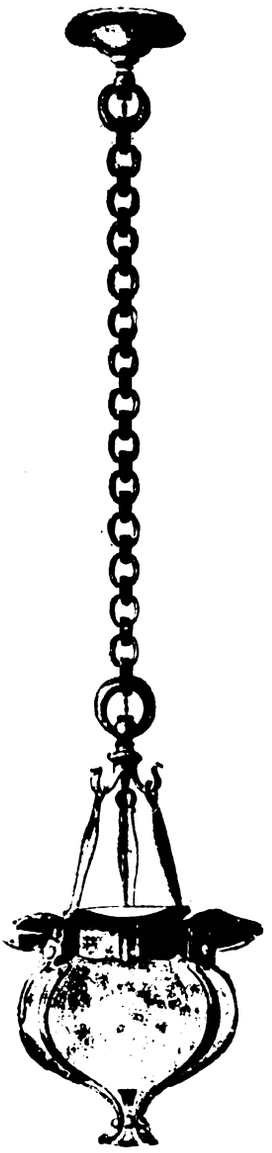

FIG. 16.

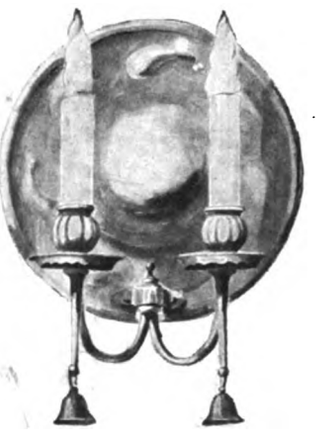

FIG. 19.

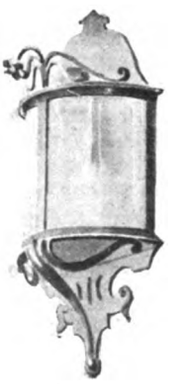

FIG. 20.

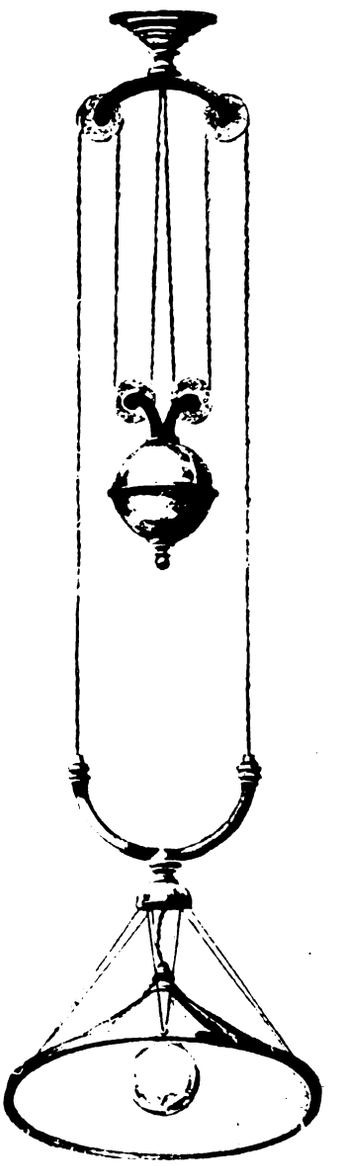

FIG. 17.

due to the fact that they make most other things, and the accommodation at Olympia is limited. But the General Electric Company's designs have an originality about them which makes it evident that a master-mind in the way of designer is behind the scenes. Fig. 14 illustrates an Adams dining-room pendant, or centre piece, with

Digitized by Google

rise-and-fall arrangement. It can be supplied with or without the top lights. The finish is in rich gilt, and the design being simple, with characteristic details, makes up a fitting to suit the style of the room without being too insistent. Far different in style is the crystal drawing-room electrolier shown in Fig 15. It was said not long ago that drawing-room electroliers, as well as crystal fittings, had gone never to return. We are glad to note that if this style of fitting is with us again it has, at any rate, been shorn of the old-fashioned, heavy appearance of those which our youth knew. This particular one is made in polished or silvered brass. It is altogether dainty and unique in design.

A simple and novel pendant in planished copper and brass is shown in Fig. 16. It is provided with an opalescent or a cider bowl enclosed by divided straps, and is very suitable for a hall or corridor.

The dressing-table is represented by a simple tilting and counterbalancing pendant illustrated in Fig. 17. This has special advantages over other makes, in that it has only one counterweight, and that the fitting itself hangs perfectly plumb. It is made in polished brass.

Figs. 18, 19, and 20 shows some pretty designs in brackets. The first is in Sheraton style, ormolu finish, and only 8in. projection. In the same style dining-room centre lights and bedroom fittings are made to correspond. Fig. 19 shows a quaint old-fashioned sconce in hammered brass, with bold repoussé work and hanging bells. Fig. 20 is a neat and unobtrusive wrought-iron wall lantern, finished in black iron, armour steel, polished, bronzed, or antique brass.

The General Electric Company are now also making wooden fittings of simple design, which should be very successful as they can be selected to match the furniture, and cost less than the metal fittings. They are made of patent fireproofed wood. The same principle has also been extended to radiators.

(To be continued.)

PRIME MOVERS AND AUXILIARY PLANT AT OLYMPIA.

BY E. G. BEAUMONT, A.M.I.C.E.

(Continued from page 443.)

The longitudinal and transverse sections (Fig. 1) show the general arrangement of the three-cylinder compound engine referred to last week as among Messrs. W. H. Allen, Son, and Co.'s exhibits. It is representative of the double-acting forced-lubrication type, which has shown itself to be preferable for some reasons to the single-acting high-speed engine. It must now be recognised that the possibility of running the double-acting type satisfactorily at the same or at higher speeds of rotation than the single-acting type, and with equally good results, discourages the construction and use of the constant-thrust engine in which the necessary use of the air buffer cylinder or other means of maintaining the running parts in constant thrust imposes a limit to the power to be obtained in a given space. That is to say, the use of the forced-lubrication system, originating or first largely used by Messrs. Belliss and Morcom, makes it possible to construct high-speed double-acting engines of less weight and occupying less room per unit of power than any other type of reciprocating engine now in use.

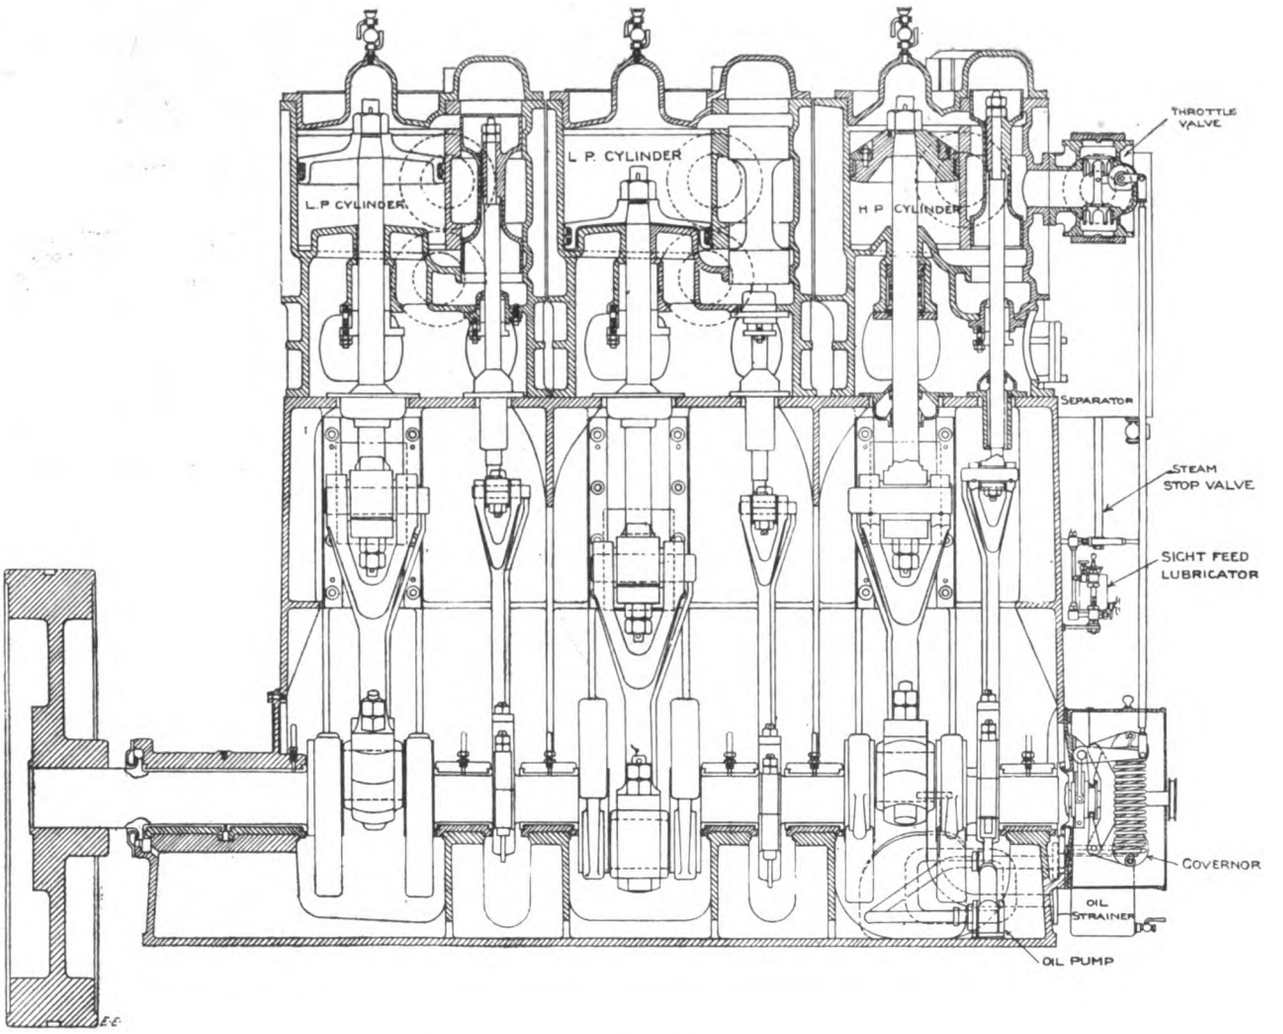

FIG. 1.—Section of the Allen Three-Cylinder Compound Engine.

The two important considerations of economical running and uniformity of turning effort have led to the design of the three-cylinder compound engine shown. For steam pressures of less than 150lb. per square inch, the useful range of expansion of the steam may be better obtained in two-stage or compound engines than in the triple-expansion engine having three cylinders, but with an equal division of work in the three-crank engine a more continuous or regular turning effort is obtainable. A compromise must therefore be made between designs involving the use of many cylinders to obtain the required division of work, but with lessened economy, and those requiring the use of few cylinders and permitting maximum economy,

Digitized by Google

but accompanied with the disadvantage of less regular turning effort.

The 440-b.h.p. engine exhibited at Olympia has a high-pressure cylinder 16in. diameter and two low-pressure cylinders 18in. diameter, the stroke being 10in. and the speed 400 r.p.m. If a perfect division of work is to be obtained in this engine, obviously the power developed in the low-pressure cylinders must be twice that in the high-pressure cylinder, but it is difficult to effect this and to also obtain a suitable temperature range. From the indicator diagrams here shown (Fig. 3) some idea may be gained of the temperature and pressure conditions in an engine of this type. The set of diagrams are from a larger engine capable of developing 1,040 b.h.p. and running on an hydraulic dynamometer at the maximum load Messrs. Allen were able at the time to obtain, which was 765 b.h.p. The division of work as shown is apparently 44 per cent. in the high-pressure cylinder and 56 per

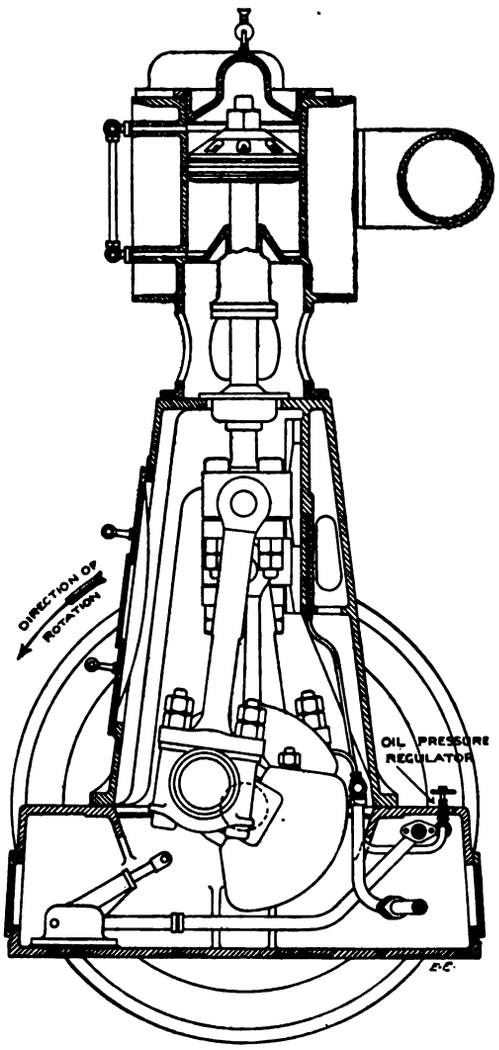

FIG. 2.

cent. in the low-pressure cylinders, but I hope to be able to show diagrams taken simultaneously which will more correctly show the work done in each cylinder and at a higher load. The engine was running during its six hours' test with a steam pressure at the stop valve of 130lb. per square inch throttled to 91lb., and this explains the sloping admission and expansion line on the high-pressure cylinder diagram. The weight of the pistons, piston rods, and connecting rods is the same at each line of the engine, and there are balance weights on the crankshaft webs. The disturbing forces productive of vibration are, therefore, to a large extent neutralised, and the engine is well balanced. The valves are of the solid piston type, and are free from the disadvantage attending the use of rings. The satisfactory use of such valves requires the very best class of workmanship and fitting and considerable experience to determine the possible closeness of fit for freedom of running without steam loss by leakage. The three cylinders are separate castings independently mounted on the crank chamber, and expansion may take place without change in the distance between centre lines and without interference with the freedom of running of the engine—a matter of importance with large engines and those running with high-pressure and superheated steam.

Mention has already been made of the 21·5-b.h.p. gas-engine and suction producer gas plant shown by Messrs. Crossley Bros. as a working exhibit. To those who have not seen this exhibit, or who are unacquainted with the general arrangement of such a plant, the illustrations here given will prove of interest. Referring to the sectional view (Fig. 4), it will be seen that the central cylindrical firebrick-lined producer chamber is separated from the outer containing shell, of cast iron in the smaller and built up of steel plate in the larger sizes, by an insulating filling or jacket of sand. The firebrick lining rests upon an annular ring or base-plate supported on two cast-iron superheater boxes upon a lower diaphragm plate. A central opening in this plate is occupied by the firebars, and the superheater boxes shown sectioned black are of segmental or semi-circular form in plan, and are exposed to the hottest part of the fire. At the top of the producer is a box through which the anthracite or coke fuel is fed to the hopper, and from which, as combustion proceeds, it descends through

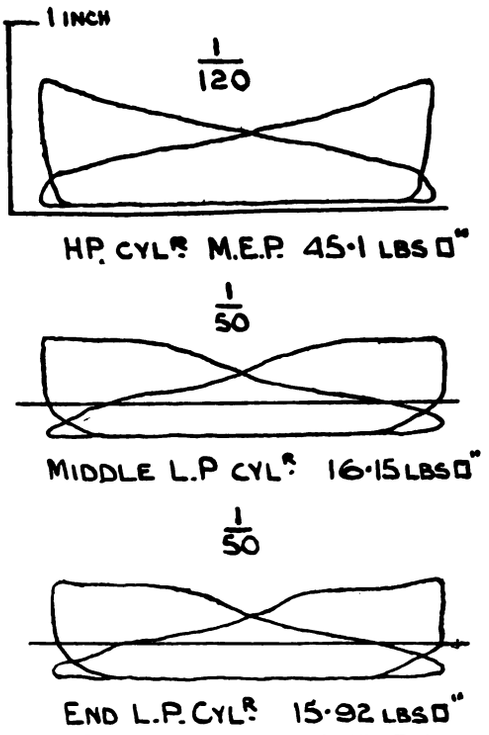

FIG. 3.—Indicator Diagrams from the Allen Engine.

the hanging neck or bell to the lower and hotter part of the producer chamber, finally becoming incandescent as it nears grate level. The quantity of fuel above the grate is determined by the downwardly projecting bell or neck of the hopper, and, as the latter must be kept charged while the plant continues in operation, the gas leaves the mass of fuel at the level of the lower end of the bell and passes upwards between it and the firebrick lining. Around the bell is an annular water chamber, forming part of the saturator or boiler, and in communication with the top vessel or saturator dish, the level of the water in the latter and the position of the water inlet pipe being indicated. There are, it will be noticed, baffle plates below the saturator dish, which cause the hot gas from the producer to take a circuitous path and to usefully give up heat to the water for the production of steam. The steam thus formed, together with air permitted to enter the saturator above water-level, passes downwards by two pipes, one of which is shown, to the superheater boxes, and leaving these at high temperature passes upwards through the grate as indicated by the arrows. The gas is thus obtained by the induced flow caused by suction from the engine of air and steam through the incandescent fuel. The process of formation is concisely stated by Messrs. Crossley Bros. Two simple reactions take place, expressed by

Digitized by Google

to the hydraulic box containing water at a fixed level, upwards through a second scrubber, and thence to an expansion box or container of some capacity before reaching the engine. The expansion box is used to provide some storage for the engine to draw upon, and to some extent to relieve the producer of, and to damp down, the small continuous fluctuations of rate of supply, and the greater variation that would otherwise be felt

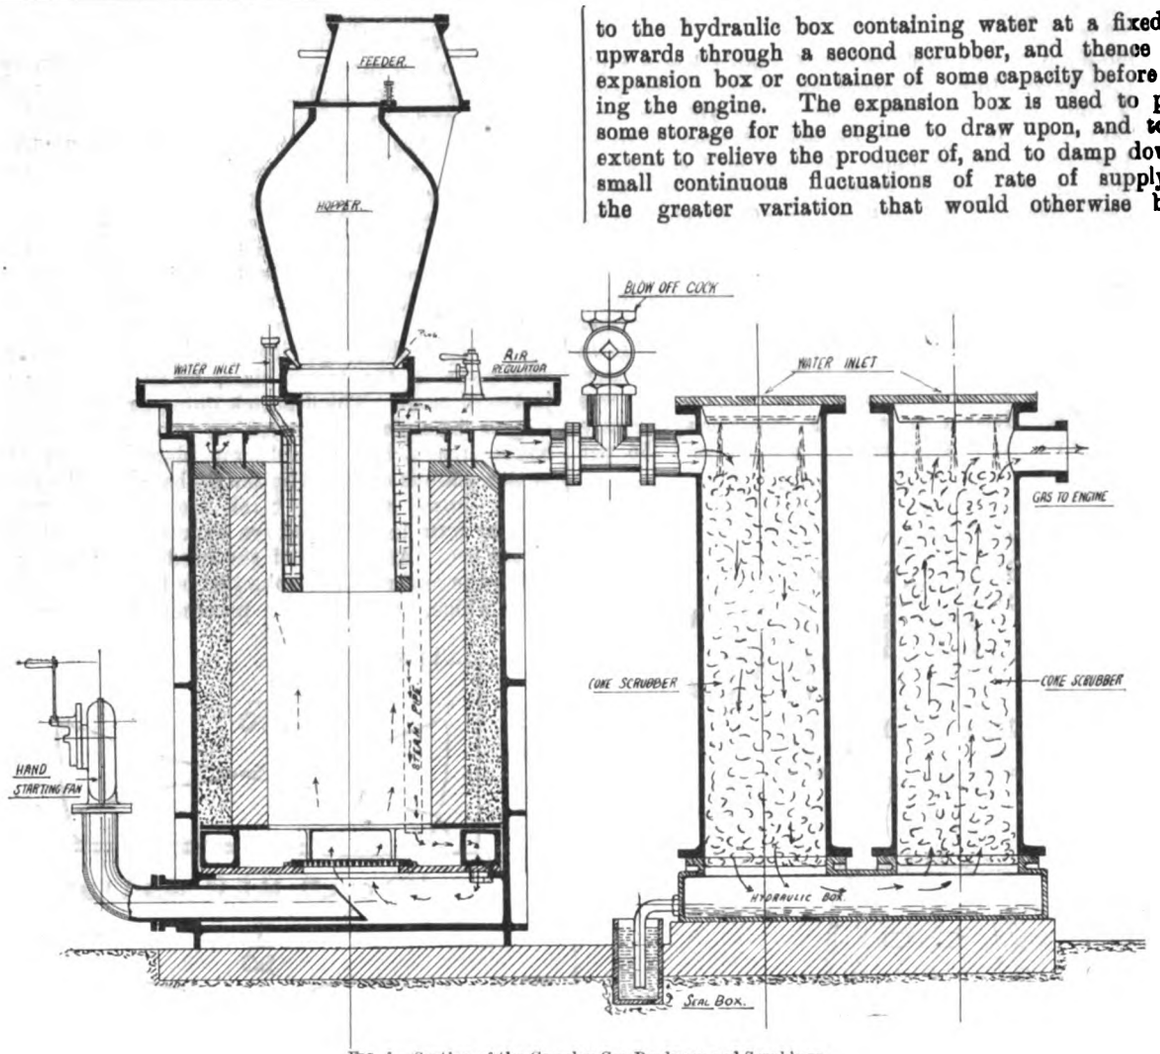

FIG. 4.—Section of the Crossley Gas Producer and Scrubbers.

$$2\,C + O_2 = 2\,CO$$

$$C + H_2O = CO + H_2$$

That is to say, the oxygen of the air combines with the carbon of the fuel to form carbon monoxide, and the water splits up to form more of the monoxide and free hydrogen. In addition to this a certain amount of marsh gas, CH_4, and carbon dioxide, CO_2, are formed, so that the ultimate composition of the gas is—combustibles CO, H_2, and CH_4, diluted with the non-combustibles, CO_2 and N_2.

when the engine is running on a variable load and with the governor cutting out working strokes. When the engine is to be stopped, the blow-off cock between the

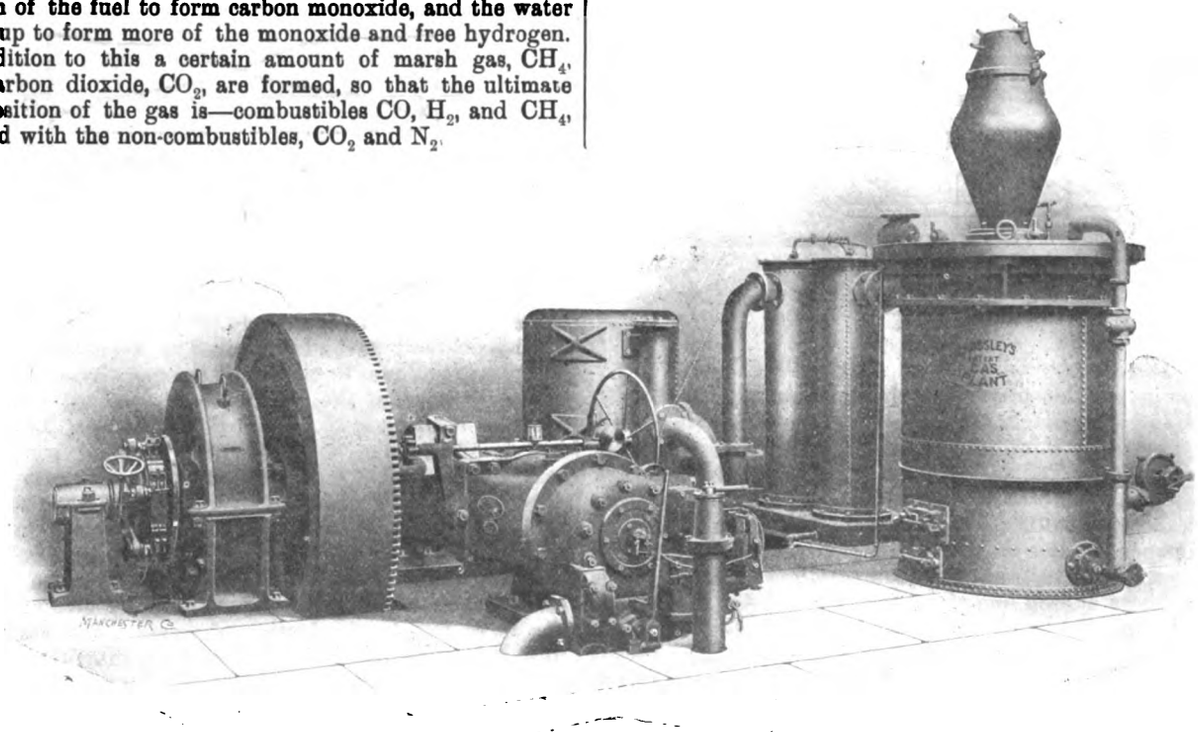

FIG. 5.—View of a Crossley Gas Producer Engine and Dynamo.

Returning to the sectional illustration, and following the course of the arrows, it will be seen that the gas successively passes downwards through a coke scrubber or washer

producer and the scrubbers is opened. Slow combustion continues in the producer, and after a stop, if it may be a day or longer, the fire may be got into condition for

Digitized by Google

restarting the engine by use of the starting fan. The suction producer is thus structurally simple; no part of it is under pressure, it may be readily examined and kept in an efficient condition, and as a power plant it is free from the objections that may be raised to other systems requiring the use of many vessels and pipes under high pressure.

Gas-engines of large and small powers have now been running for a sufficient length of time to show that the suction producer is practically and commercially satisfactory, and with the growing recognition of their successful use there will, without doubt, be a rapid increase of their use. Fig. 5 shows a producer plant designed to supply gas obtained from common gas coke as fuel to the 80-b h.p. engine to which it is shown connected. The engine is direct coupled to a 55-kw. Crompton multipolar dynamo, and the plant is one of three sets constructed for the Howrah station of the Calcutta Electric Supply Company. The following figures, selected from the results of a test conducted by Messrs. Crompton under the superintendence of Mr. H. Stevenson, M.I.Mech.E., are interesting. Gas coke having a calorific value of 12,411 B.Th.U. per pound was used.

Total fuel consumed	488lb.
Total kilowatt-hours	368·4
Fuel per hour	81·33lb.
,, kilowatt-hour	1·325 b.
,, indicated horse-power hour	0·779 b.
,, brake horse-power hour	0·91lb.
Mechanical efficiency of engine	85·57 %
Thermal efficiencies—	
Electric energy at terminals / B.Th.U. in fuel	20·8 %
B.H.P. energy / B.Th.U. in fuel	22·71 %
I.H.P. energy / B.Th.U. in fuel	26·54 %
Heat efficiency of producer plant calculated from the known efficiency of the gas engine with a cold start	89·5 %

These figures clearly establish the heat economy of such a plant supplied with inferior fuel. With plants designed to use bituminous fuel a more extended process of scrubbing and washing is required to free the gas from tarry matter, and to avoid trouble by deposition on the valves and a dirty internal condition of the engine.

Messrs. Crossley call attention to the means by which they overcome the difficulty, common to suction producer plants, of variation of the quality of the gas when the engine is running at a varying load. It may happen that a period of heavy working is followed by an idle period, during which formation of steam in excess of that required at the moment occurs. This results in the production momentarily of very rich gas, followed by cooling of the fire and the generation of gas of a poorer quality. By the use of one or more cocks opening to atmosphere and communicating with the air space above the water in the saturator dish the temporary excess of steam is discharged, and does not interfere with the steady working of the producer.

(*To be continued.*)

RECENT PROGRESS IN ELECTRIC LIGHTING AS INDICATED BY THE OLYMPIA EXHIBITION.

BY FRANCIS H. DAVIES.

(*Continued from page 442.*)

The most startling lighting innovation of recent times is undoubtedly the mercury vapour arc, with its characteristic colour, exceptional diffusive qualities, and remarkable efficiency of from six to seven times that of the incandescent lamp. At Olympia it is, at the time of writing, represented solely by the Bastian mercury vapour lamp, for which Messrs. Rumney and Rumney are agents; but the Cooper Hewitt lamp, which figured so prominently at the Holborn and Paddington exhibitions, is expected shortly to make an appearance at the stand of the Electrical Power Storage Company. It is unnecessary to dwell upon the early history of the mercury vapour lamp and the difficulties which were met with in its development. It is only needful to point out that these difficulties have been overcome, and that the mercury vapour lamp nowadays is thoroughly practical, and represents in respect of efficiency the greatest advance which has been made in artificial lighting. At the present time it is suitable only for direct current. Work, however, is proceeding, and developments in the direction of a practical alternating-current lamp may be anticipated.

The colour of the mercury vapour light, due to the almost entire absence of red rays in its spectrum, is against it from the æsthetic and in some few cases also the utilitarian point of view. But the advantages it offers in efficiency and diffusion are substantial enough to outweigh this consideration in the majority of cases. Determined attempts have been made to overcome this colour difficulty, three methods having been employed. The first and most obvious is to mix with the mercury electrodes chemicals—notably cadmium—which give a yellow or red tinge to the light. Mr. Bastian has long experimented in this direction with very favourable results, and he anticipates shortly to produce a commercial lamp of this description. The second method—one much in evidence at Messrs. Rumney's stall—consists in combining with the vapour lamp in the same lantern a small incandescent lamp, which, being rich in red rays, tones down the actnic qualities of the pure mercury vapour light. This is termed the "Daylight" combination, and is most satisfactory. With a slightly opaque shade the effect is very similar to that of an arc lamp, the combination being at the same time more efficient, as it is stated to consume only ·7 watt per candle-power. Even better results are obtained by the use of a tantalum lamp with its high efficiency, the consumption then working out at ·5 watt per candle-power. The efficiency of the mercury vapour lamp is, of course, lowered by any such combination, but, as will be seen, not to an undue extent. The third method is based on the reflected light system, and is both simple and effective. Underneath the lamp is fixed a large reflector painted internally with rhodamine, a dye which possesses the peculiar property of transforming any light impinging on it into red light. The result is that the reflected light has a decidedly red tinge, the proportion of which may be varied to any desired extent by altering the size and disposition of the reflector.

It will be seen from the above that the colour improvement of the mercury vapour light is by no means an impossibility; rather, it is an accomplished fact, not only scientifically but commercially, which is perhaps the chief consideration. Mr. Bastian's exertions in this direction have been most persistent, and it is a pleasure to record that they have met with so much success. The mercury vapour lamp appears to be one of the best weapons wherewith to combat high-pressure gas for outdoor lighting, and any improvements in it should be accorded a hearty welcome by electrical engineers.

It may not be out of place to point out the difficulty which is met with in photometric work with mercury vapour lamps. Owing to the distinctive colour of the light, a photometric comparison with a known standard is of little value, and in this respect the vapour lamp is in the same position as the arc. Results obtained vary very largely with the distance at which they are taken, and bear no definite proportion, but it has been definitely ascertained that the mercury vapour light has by far the greatest penetration, particularly in fog, owing to its actinic nature.

While on the subject of mercury vapour lamps, the great progress made by the Cooper Hewitt lamp in all purposes appertaining to photography should be noted. These lamps are now adapted in special outfits to every branch of such work, and the economy they effect in current consumption over systems employing the arc lamp is as marked as the better quality of the work they produce. It is interesting to note that with the Cooper Hewitt lamp no condensers are required in the making of lantern slides or bromide enlargements, the interposition of an opal or ground glass between the negative and the lamp being sufficient. The diffusive nature of the light is, of course, of the greatest value in photographic work, and this, in conjunction with its other characteristic features, gives the Cooper Hewitt lamp a high place in the record of progress. The large area from which the light emanates in this lamp is responsible partly for the unusually good diffusion, which makes it

Digitized by Google

specially suitable for the illumination of large open spaces with single lamps.

The tantalum lamp, which is shown at Messrs. Siemens's stall, is arousing much interest, as, despite its present limitations, it is a lamp full of promise. Tantalum, the metal of which the filament is made, has about the same electrical resistance as platinum, the same hardness as mild steel, and a tensile strength somewhat greater than the latter. It makes up into a strong filament, but softens with use, and becomes somewhat friable. Being a metal it is by no means strong when in a state of incandescence, and for this reason will not stand vibration and shocks which would leave the ordinary carbon-filament lamp unaffected. The resistance of tantalum wire being practically the same as that of platinum, a considerable length has to be disposed of in the lamp globe, and this has proved one of the chief difficulties in the construction of a commercial lamp. Many schemes have been tried, but the present one, which consists of looping the filament in a birdcage fashion over wire arms fixed in a central rod of glass, has proved the most satisfactory, and gives a good distribution of the light. According to Prof. W. Ambler, who has recently read a paper on the subject before the Ohio Electric Light Association, a filament for a 110-volt lamp of 22 c.p. requires a wire 65cm. long and 0·05mm. in diameter, having a weight of 0·022 of a grain.

The great advantage of the tantalum lamp lies in its extremely high efficiency. It takes only half the current of an ordinary carbon-filament lamp of the same voltage and candle-power; consuming at the beginning of its life about 1·7 to 1·93 watts per candle-power, as against 3·5 to 4 watts per candle-power, the usually accepted figures for a good incandescent lamp. Its present high price of 4s. is, therefore, not such a great disadvantage, as the economy of the lamp saves more than the difference in prime cost in a short time. From all accounts the life of the lamp is rather short, about 500 hours; but there appears to be very little authoritative information on this point, and in some places an average normal life of 1,000 hours is claimed. The falling off of candle-power with age is about the same as that of the carbon-filament lamp, but it is claimed for the tantalum lamp that it is entirely free from blackening of the globe, which is a very good feature. The great disadvantage at present lies in its unsuitability for circuits of over 125 volts. On the ordinary commercial 220 or 230 volt circuit two lamps have to be burnt in series, which, of course, means alteration of existing wiring, besides the other disadvantages attached to series running. In the case of new private plants these objections do not hold, and the lamp might be used in this field with advantage. There is every reason to anticipate a reduction in its price, since the present high amount is due chiefly to difficulties in manufacture which presumably will be overcome, and not so much to high cost of material. The behaviour of the lamp as regards variation of efficiency and candle power with voltage is shown in Fig. 2, which contrasts the performance of carbon-filament and tantalum lamps in these respects. It will be noted that the efficiency of the tantalum lamp varies only slightly with the voltage as compared with the carbon-filament, and that the candle-power also is not so much affected. The reason of this is that the resistance of the tantalum filament increases with heat, whereas that of the carbon filament decreases. This figure is based upon the curves given by Prof. W. Ambler in his paper above referred to.

The osmium lamp, which is being shown by the General Electric Company, has been brought to its present position, verging upon practicability, by Dr. Auer von Welsbach, of incandescent gas fame. Many difficulties have been encountered in the making of an osmium filament, owing to the extreme brittleness of the metal. An ingenious method has, however, been devised, whereby powdered osmium is mixed into a paste by the assistance of an organic binding material, and a filament produced by the forcing of this paste through a die. It then passes through various processes, and, finally, is sealed into an exhausted globe in the same manner as the carbon incandescent lamp. Difficulty was experienced in the early days in making a lamp capable of working at any commercial pressure, and the first osmium lamp to be produced was suitable only for a 37-volt circuit. This, however, has been improved upon, and 110-volt lamps are now made with a spiral filament of considerable length. Like the tantalum lamp, the resistance of the osmium filament increases with heat, and it is, therefore, less susceptible to voltage variations than the carbon lamp. An efficient life of 2,000 hours seems to have been frequently attained, and in some cases even 5,000 and 6,000 hours have been reached. Fig. 3 is self-explanatory, and gives a good idea of the effect of age upon the efficiency and candle-power of osmium lamps. The curves were plotted from results obtained at the Technologischen Gewerbe Museum of Vienna, where severa lamps were tested of the original 35 volt class; but it stated that the recent lamps of higher voltage show equally good characteristics. Although carbon-filament lamp makers have nothing to fear from either the tantalum or osmium lamps at present, it would be rash to conclude that

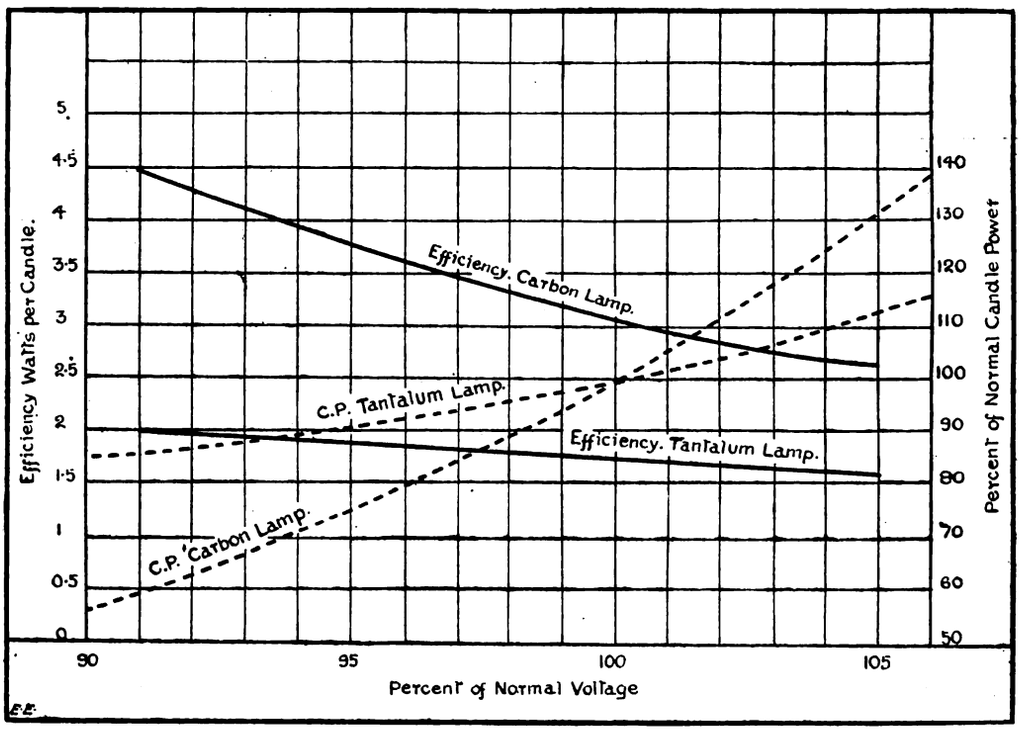

FIG. 2.—Curves showing comparative Variation of Candle-Power and Efficiency with Voltage. Carbon Filament and Tantalum Lamps.

Digitized by Google

such will always be the case. It is conceivable that the difficulties with which they are hedged round will in time be conquered, and if one is prepared to go so far as to expect confidently that this will ultimately be the case, the only logical conclusion to draw is that the carbon-filament lamp in its present form is doomed.

The Nernst lamp, which is very much in evidence at the exhibition, has made steady progress in popularity, particularly in the last year or two. It has upon many occasions saved the situation where street-lighting has been in danger of a relapse to gas, and there is no doubt that for this, and, indeed, most illuminating purposes, it is a decided success. Its future, like that of the carbon-filament lamp, is bound up in the success or failure of lamps of the tantalum and osmium class, and perhaps the mercury vapour lamp; and very decided advances will have to be made in many directions if it is ultimately to compete with these lamps accentuated in value by improvements which may denude them of all their objectionable features. It is quite impossible and futile to predict what may happen in this direction, but there can be little doubt that developments will be made, and that these will probably take a somewhat startling form. A notable improvement of the Nernst lamp is the type called the "Express," as it gets over the difficulty of slow lighting up. It is fitted with two ordinary incandescent lamps at the sides which light immediately the switch is closed, being cut out automatically directly the glower has attained the necessary temperature.

The ordinary carbon-filament lamp appears to have progressed chiefly in the direction of cheapness, owing to improved methods of manufacture. Other advances have been made, but with the exception of such improvements as turn-down lamps, and devices such as the "linolite," they are not particularly noteworthy. The mechanical pump has almost entirely replaced the mercury pump for exhausting the globes, and the working exhibits of the Ediswan and Robertson Companies afford excellent examples of the improvements effected by its use. Small details of lamp manufacture are always varying, but on the whole there does not appear to have been anything startling in the way of progress during the last few years. Life and efficiency remain about the same, and the price seems to have reached a dead level. Several firms now make incandescent lamps which, instead of diffusing their light more or less equally in all quarters, throw it chiefly in the direction where it is most needed, and this certainly constitutes an improvement for many purposes.

The Linolite Company's exhibit is interesting, and affords an excellent opportunity for appraising the value of their

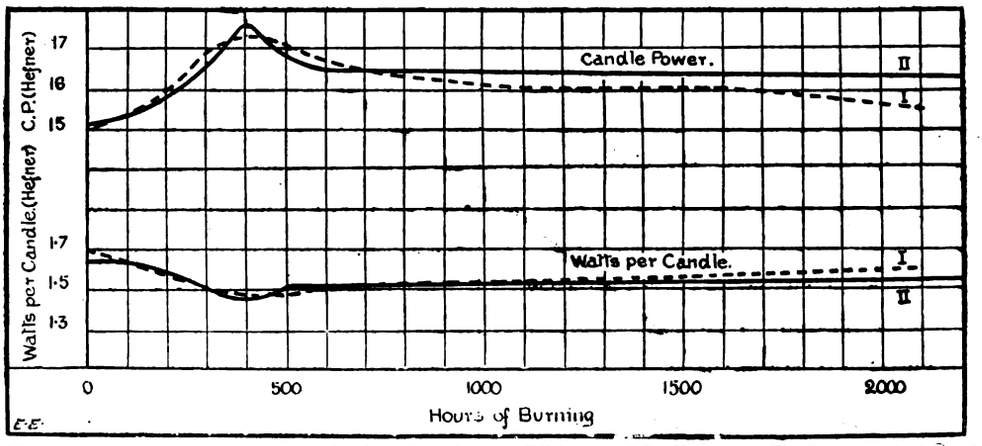

FIG. 3.—Tests of 16-c.p. (Hefner) 35-volt Osmium Lamps, showing effect of Age on Efficiency and Candle-Power. The Curves marked I. and II. represent the average behaviour of two batches. N.B.—One Hefner unit = ·877 of the British standard candle.

speciality. That this is considerable is obvious to any observer, and, if proof were wanted, it is at hand in the popularity which the system has attained for shop-window lighting. There is no question that for many purposes it is superior to the ordinary incandescent lamp, even when the latter is shaded by a reflector, since the diffusion of the light is better. The company are publishing some remarkable photometric tests, made at the Manchester Municipal School of Technology, which show that the efficiency of the Linolite system is extremely high as compared with that of the ordinary lamp. There is no doubt that the reflected light system comes the nearest to the ideal, and the Linolite Company's method is, indeed, a very good example of it.

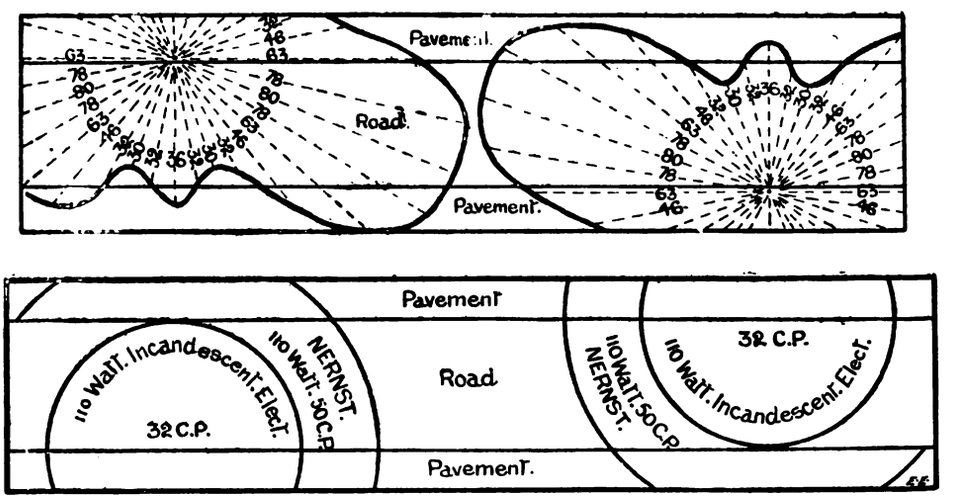

FIG. 4.—Diagram comparing the Lighting Effect produced by Street Lamps provided with good Reflectors and Plain Lamps.

Their manner of expressing the cost of lighting in terms of yards run of lamp per hour is singularly apt, and just the way to appeal to laymen. The figure given is 1d. per yard per hour with current at 6d. per unit.

Street-lighting by incandescent or small candle-power lamps is a subject which has received special attention by many firms, notably Messrs. Drake and Gorham and the Reason Manufacturing Company. Much progress is shown here, fittings of many descriptions having been devised with a view to making the most of the light and throwing it in the directions where it is most needed. It is well known that in street illumination by plain lamps much of the light is wasted—part being projected upwards, and so

Digitized by Google

absolutely lost, and part falling on house fronts, where it is little needed, and to a great extent lost unless these happen to be white and reflective. To cope with this waste, reflectors are now commonly used, and if well designed and tended, they considerably improve the general effect by distributing the light in a proper manner. The results obtained with a good reflector and with a plain lamp are compared in Fig 4, which is based upon tests carried out by the Reason Manufacturing Company on one of their latest type of reflecting fittings. The upper diagram gives the light distribution in candle-power for two 16-c p. lamps and reflectors; the lower shows the results which are obtained when using Nernst or incandescent lamps absorbing the same energy but without reflectors. It will be noticed that the lighting effect is much better in the former case, being greatest in a direction parallel with the road, and least at right angles with it.

Although arc lighting generally was dealt with in the first section of this article, it may not be out of place to call attention here to the two large "Excello" arc lamps recently erected since the exhibition opened by the Union Electrical Company. These are probably the most powerful automatic arc lamps in existence, as the light they give is stated to amount to 20,000 mean hemispherical candle-power. The lamps require 25 amperes at 70 volts across the terminals, and they therefore possess the remarkably high efficiency of about 10 c.p. per watt. Direct current for these lamps is obtained from the Diesel oil-engine set.

In the foregoing survey of electric lighting progress as shown by the Olympia Exhibition it has been impossible, from considerations of space, to mention all and sundry of the improvements in lighting there on view. Not one, but many visits must be made to gain even a general idea of the advances which have taken place in the last few years. Engineers will, of course, be familiar with most of these, if not personally, at least through the columns of the Press.

The exhibition, however, affords an opportunity of seeing them actually in operation, which is far better than any amount of written description. It leaves one with the impression that the outlook for electric lighting is better than it ever has been, and the exhibition should prove a most useful object lesson to those in authority who have lately been considering the advisability of a retrograde step to gas for street-lighting. If such a step be taken, there can be no doubt that it will be regretted. Flame and midget arcs, the mercury vapour lamp with red rays, and the latest forms of incandescent lamp are comparatively new things, and some of them have scarcely issued from the experimental stage. All, however, are either more efficient or more suitable for street-lighting than the appliances we have been using so far, and it is only fair, and only common sense, that these and their possibilities should be carefully looked into before any decision—such as a relapse to gas—involving radical alterations and large expenditure is arrived at. That such a step, if taken, could only be temporary is every day becoming more apparent. Electrical men are alive to the necessity for improvement, and improvement there will be.

(To be continued.)

IMPERIAL NOTES.

AUCKLAND, NEW ZEALAND.

Auckland is the chief city in the provincial district of Auckland. It is situated on the southern shore of the Waitemata harbour, and adjoining it are the suburban boroughs of Grey Lynn, Parnell, and Newmarket, whilst on the opposite or northern side of the harbour are the boroughs of Birkenhead and Devonport, the means of communication being by ferry service. Auckland is most fortunately placed in having such a magnificent harbour opening upon the east coast, as well as a harbour at Onehunga, which opens on to the west coast. This latter port is but eight miles from Auckland, and is connected with it by both railway and electric tramway. The city was founded in 1840, and was the capital of the colony until 1864, when the seat of Government was removed to Wellington. The population of the city, together with its suburbs, is approximately 70,000.

Tramways.—Auckland was the first city in New Zealand to establish a system of electric tramways. A concession for a period of 32 years was granted to the Auckland Electric Tramways Company, Limited, by the City Council and by the councils of the adjoining suburban boroughs. This company was formed in 1899, and acquired the old horse tramways (about 10 miles of single track)

Permanent Way and Equipment.—The length of single track is about 30½ miles, laid along a street route of over 18 miles, and extends as far as Onehunga, the port for Auckland coastal steamers on the west coast. The gauge is 4ft. 8½in., and the tracks are laid 6ft. apart. The rails used are of the flanged girder type, and for the most part weigh 92lb. per yard, but for special work at curves the weight is 95lb. per yard, all in lengths of 37ft. The sharpest curve has a radius of 40ft., and the steepest grade, about nine chains in length, averages 1 in 8·8, although there are much longer grades of 1 in 11. The rails are laid upon concrete foundations 18in. wide by 9in. deep, the track between these concrete foundations being formed with 9in. of broken metal. The rails are protected on each side by a row of stone setts laid alternately header and stretcher. To this class of construction and to the treacherous nature of the earth foundations must be attributed the frequent and expensive lifting and relaying of the track, although the lines have only been open to traffic for so short a time. In Queen-street, the main street of the city, the tracks are paved with Neuchatel asphalt on a 6in. concrete foundation. The points used are 7ft. 5in. in length, curved, the facing points being connected and fitted with the usual spiral spring and lever arrangement. The tracks are well drained at frequent intervals by transverse culverts connected with the street gullies. In the greater part of the track iron centre poles are used, whilst at junctions and curves, and in some few districts, the method of supporting the trolley wire is by means of span-wire construction, and again, in some instances, side poles and bracket arms have been adopted. In the outlying districts the poles are of Totara timber. The trolley wire is No. 00 B S G. Here, as in the case of Wellington, considerable expense has been incurred in raising the telephone and telegraph wires, which are all overhead. In the central part of the city the feeder cables are laid in underground conduits of earthenware, and outside, and as far as possible, these feeders are carried overhead on cross bars attached to the poles, and are of bare copper wire No. 4/0 B S.G. The trolley wires are divided into half-mile sections by the usual boxes.

Power Station.—The power station is situated near to Queen-street and to the harbour. It is built in two levels, the engine-room, 104ft. by 53ft., being on the higher level, and the boiler-house, of the same dimensions, on the lower level. The building is erected in brickwork with steel framing. In the engine-room there are three engines of the horizontal, cross-compound, Corliss type, each of 475 i.h.p. with normal load and 700 i.h.p. with maximum load, running 100 revolutions, with 150lb. steam pressure. The maximum steam consumption at full load working with condenser is 14½lb. per indicated horse-power per hour. There are three 300-kw. continuous-current generators capable of a 50 per cent. overload, one 25-kw. generator, and four boosters, and recently an additional 600-kw. generator has been installed. The switchboard consists of 17 panels of marble, and there is a 20-ton travelling crane. In the boiler-house there are four Babcock and Wilcox water-tube boilers, each with over 2,000 super feet of heating surface, and fitted with chain-grate stokers. The economiser is one of Green's, the scrapers of which, as well as the feed pumps, are worked electrically. In addition there are the usual injectors, filters, hot-well, piping, etc. The chimney stack is of steel (lined for one-third of its height), 125ft. high and 7ft. diameter. The condensing water is obtained from the harbour, some considerable distance away, by means of two electrically-driven centrifugal pumps, each capable of delivering 500 gallons per minute. The two surface condensers are capable of condensing 35,000lb. of steam per hour, and these, together

Digitized by Google

with the air-pumps, are placed in the basement part of the engine-room.

Car-Sheds.—There are two car-sheds—one at Ponsonby and the other at Alexandra Park at Epsom. The former is the principal depôt and contains all the repairing shops, etc. This shed is constructed in two divisions, each 39ft. wide by 354ft. and 328ft. long. There are six track lines with inspection pits under. There are also the usual machine, blacksmiths', painters', and erecting shops, stores, etc., fitted with overhead traveller, lathes, drilling machines, and other necessary tools and appliances.

Rolling-Stock.—The rolling-stock of the company consists of 55 cars of various designs, including double-deck bogie cars to seat 80 passengers, with four motors; single-deck bogie cars to seat 48 passengers, with two motors (these cars are of the combination type, with open ends and closed centres); single-deck four-wheel cars to seat 32 passengers, with two motors (these cars are divided into two compartments). The seating of these cars cannot be regarded as comfortable, an effort having been made to accommodate as many passengers as possible at the expense of passage room. The wheel base of the bogies is 4ft 6in. and of the single-truck cars 6ft. 6in., and the motors are 40 b.h.p. Owing to the severe grades the cars are fitted not only with the hand brake and electrical emergency brake, but also with a slipper brake on each truck. The cars are fitted with guards at each end, which drop automatically when they come into contact with any resistance. The cars commenced running on the section of the system first opened in November, 1902, and at the last annual meeting of the company it was reported that the traffic receipts for the year had been £110,573, and that over 18 million passengers had been carried in that period, or equal to 250 times the population served. The greatest number carried in any one day was 98 023. The net profits for the year amounted to £26,275, and a dividend of 6 per cent. on the share capital has been paid.

Destructor.—The Corporation have recently completed a refuse destructor at a total cost, exclusive of land, of £16 000. This is one of Messrs. Meldrum's Simplex type, and the contract was carried out by their Sydney agents, Messrs. J. Barre Johnston and Co. It is intended to utilise the power derived from the destructor in the generation of electricity.

Christchurch, New Zealand.

In reference to our note about Christchurch in last week's issue it should have been added that the gasworks are in the hands of a private company, the price charged per 1,000 cubic feet of gas being 6s. 3d. net. The City Council have set up a committee to consider the advisability of purchasing the company's property. The paid-up capital is placed at £120,000, and the present market value of the shares at £225,000.

Wellington, New Zealand.

Similarly, it might have been added in regard to Wellington that the gasworks there are also company owned. The Council promoted a Bill in the last session of Parliament for the acquisition of these works, the value to be fixed by arbitration. The Bill was, however, not reached. To ordinary consumers the net price of gas is 5s. 10d. per 1,000 cubic feet.

A Complaint from Canada.

Electrical machinery of English manufacture seems to have gained ill-repute in some quarters through causes which are not far to seek. It is a thousand pities, since pronounced failures, although they may be confined to a particular type of machine, are apt to reflect unfavourably on the source of supply as a whole. Following is a case in point. A correspondent writes to us from a town, which shall be nameless, in the province of Ontario, Canada, that electrical machinery sent out there from this side has not always been to the credit of English manufacturers. A number of English machines which have been placed in the district during the last two years have given very poor satisfaction, being too light of build, and not possessing, it is claimed, the staying power of Canadian machines, such as are supplied by the Canadian General Electric Company, Peterborough; the Westinghouse Electric Company, Hamilton; and the Bullock Manufacturing Company, Montreal.

From his own observations our correspondent concludes that the English manufacturer not only builds a much lighter machine, but sells it at a lower price than his Canadian competitor, and while the English machine compares favourably in regard to electrical efficiency with that of Canadian make, when it comes to continuous wear the former has relatively little staying power and breaks down—then begins the repair bill. As a typical instance he mentions the case of a 1,000-kw. English machine installed three miles distant from his own plant, which latter is a 1,500-kw. Canadian General Electric machine. Both machines are now running in their third year. The Canadian-built machine, although carrying a heavy load continuously, has never cost a cent for repairs or caused a single stoppage, whereas the English machine has burnt out more coils than it originally had, and has been almost constantly under repair, the coils for replacements having, in addition, to be sent out from England. In another case, where a contract was secured by an English firm for a 400-kw. machine, the price was 3,000dol. less than the Canadian manufacturers quoted. Moreover, the English machine was nearly 3,000lb. less in weight than the Canadian, and, while it has been in use but a year, has already burnt out several coils.

Our correspondent says he could give other instances of a similar nature, and further contrasts this state of things with his experience of operating over 1,000 kw. in electrical motors of Canadian manufacture during the same time without having had a single burn-out, notwithstanding that the age of some of the motors is over eight years. They are all of the alternating-current induction type. Now it is evident that this correspondent has a very poor opinion of English-made electrical machinery, and not, apparently, without reason, for there is nothing impossible in the experience recounted above. It is only rough that electrical plant of English origin should be thus condemned wholesale as the result of the failure, presumably, of a type which is no longer in vogue even here. For without seeking further details it is easy to designate the type of machine which has caused this complaint. There was a time not far past when a tendency existed to make every consideration in the design of alternate-current generators secondary to that of electrical efficiency, and the ease of replacing armature coils. It amounted almost to a craze with some inventors, and extremes of efficiency were obtained at the expense of mechanical rigidity, the greater importance of reliability being lost sight of. Then came the reaction and inductor alternators without moving coils, which found many advocates—machines which possessed the maximum possible staying power, but were of comparatively low electrical efficiency. The final outcome is a compromise between the two types, combining good electrical qualities with mechanical stability sufficient for all requirements. Modern electrical plant of English manufacture need fear no comparison with Canadian or any other productions, either in respect of electrical or mechanical design.

Our friend's conclusion that English machines are generally of too light construction is obviously wrong, and can be based only on exceptional experience. The description was true of a certain type which is no longer in vogue, but does not apply to-day.

FORTHCOMING EVENTS.

Monday, Oct. 9.

Lancashire Electric Power Company.—At 1 p.m., opening of the Radcliffe power station by the Earl of Derby.

Wednesday, Oct. 11.

Dynamicables.—At 7 p.m., dinner at the Electrical Exhibition, Olympia.

Thursday, Oct. 12.

Institute of Sanitary Engineers.—Visit to Lots-road generating station.

Institution of Civil Engineers.—Nov. 7, at 8 p.m., inaugural address by Sir Alexander Binnie and presentation of awards.

EDUCATIONAL.

Our reviewer on another page calls attention to the strong opinion of Prof. R. H. Smith upon an educational question expressed in his recently issued book on "Electric Traction," and admirably exemplified in his treatment of the subject. Prof. Smith's view is that "constructional principles and details" form only one moiety of technical education, and that "commercial results and economic conditions" form the other moiety. As we understand the view, it recommends teachers and books to combine the constructional and commercial. We agree with our reviewer that the combination will not commend itself generally. Of course, the economical moiety is of more importance to one class of men than the constructional, and *vice versâ*. The value of a knowledge of the laws of economics, like a knowledge of history, or geography, or language, is of great importance not only to technical students, but to all business men, and so convinced is the present writer of this that some forty years ago he prevailed upon the late Prof. Thorold Rogers to discourse upon the best methods to be pursued in getting the subject taught generally in our schools. We believe the lack of knowledge relating to economics is the cause of much or most of the misery and unemployment in the world. The late H. T. Buckle, in his "History of Civilisation," states truly and concisely the law relating to wealth. On p. 195, *et seq*, vol. i., of his history he discusses the work of Adam Smith and free trade. The latter we are not discussing here and now, but may say we entirely agree with Adam Smith, with Buckle, also with Chamberlain, and imagine there is no difficulty in reconciling the positions of these three giants. What, however, we desire to call attention to is the following (pp 197-8, vol. i., of Buckle): "But when it was once clearly understood that gold and silver are not wealth, but are merely the representatives of wealth; when men began to see *that wealth itself solely consists of the value which skill and labour can add to the raw material* [the italics are ours], and that money is of no possible use to a nation except to measure or circulate their riches," etc. So far as the majority of technical students are concerned, the law "that wealth itself solely consists of the value which skill and labour can add to the raw material" is all they can need. The economics that lead to success in business are of a distinctly different calibre, and should be thoroughly known to those responsible in commercial transactions. Skill and labour both have quantitative values — the more skill and the more labour the better the result. Labour unskilled has little or nothing to do with technical education, but skilled labour is in a different position. Technical education tries to show how labour can be used to the best advantage, and how skill and experience may lead to improvements. Of course, economics underlie all this, but it is not necessary for a student to trouble himself about the economics of commerce to use his skill and his labour to the best advantage. If Buckle's interpretation of Adam Smith's teaching is correct, what a degenerate age is the present, when labour, skilled or unskilled, thinks that a minimum rather than a maximum is worth striving for, and that minimising labour of the individual is the way to give labour to more individuals. A more incorrect view of the realities of the case could not be suggested. Confining the view to labour, the proper position for the wealth of the individual and of the community is to be found when each individual produces to the best advantage during his working years. Just in the same way, the greater the individual skill and the better its application, the greater the benefit to individual

Digitized by Google

and community. Skill and the best methods to apply it is the work of our technical schools—or, rather, they should give the training which will be best adapted in practice to obtain a maximum result from the individual.

THE DYNAMICABLES.

In olden days, when exhibitions came thick as autumn leaves in Vallombrosa, the Dynamicables were always well to the fore, and did their level best to assist in the success of the show. We are glad to find that the present committee has risen to the occasion, and is engineering a dinner to be held at Olympia on Wednesday next, the 11th inst., at seven o'clock. It is pretty generally known that the society is limited to a hundred and one members, but each member can invite as many guests as he likes, and dining accommodation will be found by Messrs. Lyons and Co., who catered for the society at the Trocadero. We trust that members will make a great effort to attend and introduce as many guests as possible, in order to show appreciation of the excellent electrical exhibition now open, and to encourage promoters and exhibitors, who in these days require all the encouragement they can get.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE ALL-STEEL RAILWAY CAR.

SIR,—All-steel railway carriages are no novelty, as they were tried over 50 years ago in England with disastrous results. The carriage constructors at that time had as extravagant hopes as the Brush Company now have, but railway passengers avoided the cars as they would a pestilence. The extreme sensibility of steel to heat and cold makes it an undesirable material for anything in railway-carriage construction save the framework, and the discomfort and awful feeling of shivering and cold which a winter journey in the all-steel carriages produced was quite sufficient to soon cause passengers to hate the cars. Comfort in every sense is the main thing that attracts passengers, and no material for car finishing affords this in so high a degree as wood does, because wood neither attracts nor retains heat or cold as steel does, and non-inflammable wood is even less conductive than ordinary wood.

I am afraid that the Brush Company and the new tube companies are making a costly error in adopting for car interiors a material which will chill passengers to the marrow in winter and give them an unwanted Turkish bath in summer, and that the doctors and undertakers will reap far bigger profits than the owners of the cars are ever likely to see.—Yours, etc., EXPERIENCE.

FEED WATER.

SIR,—In a supplement to the *Electrical Engineer* of Jan. 31, 1902, an article upon "Boilers and Water Supply," by F. G. Ansell, is written, and a part of the paper reads: "The effect of any such water upon a boiler may be ascertained by merely plunging a clean knife blade into the suspected sample and leaving it there for a few hours. If the knife blade has been attacked in the least, the polished surface will easily show it, *and that water should not be allowed to enter a steam boiler* until it has been properly treated to render it alkaline." This effect we get from our condensed steam. What is the remedy? Can F. G. Ansell or any reader tell us?—Yours, etc.,

JAMES CONWAY, S. T. and M. E T. Co.

Stockton-on-Tees, Oct. 3, 1905.

Derby.—The Town Council have accepted the tender of Milnes, Voss, and Co., Birkenhead, at £3,745, for the supply of six cars, with top covers; and that of W. Walkerdine, at £2,298. 12s. 3d., for the extension of the car-sheds and the provision of a shed for sand drying.

WIRELESS TELEGRAPHY.

BY W. DUDDELL, M I E E.

A course of popular lectures on the uses of electricity is being given under the auspices of the Institution of Electrical Engineers at Olympia in connection with the Electrical Exhibition. The following is a condensation of a lecture on wireless telegraphy—the first of the course—which was delivered on Friday evening last, Sept. 29, by Mr. W. Duddell, M I E E.

The subject on which I am going to address you to-night is wireless telegraphy It is called wireless telegraphy, perhaps, rather inappropriately, because in actual use a great deal of wire is employed in this form of telegraphy; nevertheless, the term has been adopted for telegraphing between two stations which are not connected by ordinary wires—that is, wires on poles, like the ordinary telegraph wires that you so well know Wireless telegraphy is really of great antiquity Probably some of our earliest forefathers used wireless telegraphy, for there is not much doubt that they signalled to one another, if they were at a distance, by using their hands or other things, and had no wires to connect the two places between which they signalled. In fact, if the ordinary method of signalling had been this wireless telegraphy that I am going to demonstrate to you to-night, and anybody had come forward, as they did early last century, and invented telegraphing with wires, nobody would have thought it very wonderful, whereas, owing to the advance made during the last century in telegraphing with wires, we have become so accustomed to every message we send travelling that way that it is looked upon as something strange if we say we shall signal from here to York without any wire.

The very earliest systems in use for signalling without wires were systems which employed the leakage of an electric current through the earth and also the magnetic effect of an electric current. I am going to show you presently some of these effects experimentally, and as I know some of my audience here are technical men, I shall use technical terms in the course of the lecture, but as there are many who are not technical men, I shall have to enter a great deal into details in order to explain the operation of this form of signalling. Well, as I said, the earliest forms of signalling were carried out by means of currents. If you put an electric current into one place in the earth and take it out at another, the current will flow in a straight line between these two places, but at the same time it will extend in all directions, and if a suitable apparatus is connected between two points in the earth you can pick up these signals. When an electric current passes through a wire, there extends round that wire what has been called the magnetic field. That fact, by use of suitable sensitive apparatus, has been utilised for signalling between very far distant stations.

In the early days Sir William Preece, then engineer-in-chief to the Post Office, took up this method of signalling, and he developed it with the assistance of his staff very considerably, and successful communication was carried out at, I believe, a distance of seven or eight miles. This method of signalling has been overshadowed of late years by a method which has been largely brought to the front by Mr Marconi, and although signalling by means of leakage currents or magnetic induction is still in practical use at a few places, it has been largely overlooked by the public in view of the greater distances and the greater apparent wonder of signalling by means of Hertzian waves, and, therefore, I shall make no apology to you to-night for devoting the major part of my time to considering the method of signalling by means of Hertzian waves. I have already shown you, by means of a simple needle, that when an electric current flows through a wire it exerts a force outside the wire. This action has very much occupied the attention of scientists during the last century, and even before that, for you have here a wire carrying an electric current, and it is capable of exerting a force and doing something at a distance. What is there between the wire and that something which enables the current through this wire to do the something away from the wire at a distance? Scientists, in order to explain this, have assumed that all the space around the

Digitized by Google

earth and around all bodies is filled with an all-pervading substance which they call ether, and that it is this ether which enables the current to create the force and turn the needles at a distance. If I charge any body with electricity, it also is capable of exerting a force. This is known as electrostatic force, and that produced by a current or a magnet is magnetic force.

Having mentioned these primitive details, I will now refer to the work of Prof. Clerk Maxwell. Prof. Clerk Maxwell, considering these magnetic electric forces produced in this body called the ether, which the scientists have assumed surrounds the earth and pervades all bodies, came to the conclusion from mathematical reasoning that if you could produce an electric force which was not constant, but by breaking you could make it alternate sufficiently frequently, then there would be produced in this ether a sort of wave which would have all the properties of light In fact, he gave a complete explanation of all the phenomena of light based entirely on considerations of these electric and magnetic forces. This early work of Prof. Clerk Maxwell was verified experimentally by Heinrich Hertz, who demonstrated all the properties of these electric waves, and actually showed that you could perform with these waves all the ordinary experiments that can be performed with light, such as reflection, as a beam of light is reflected with a mirror; that you could concentrate them with lenses, and that you could measure their velocity in travelling from one place to another. He also showed that they travel with identically the same velocity as light. In fact, the only difference between the waves in the ether or the Hertzian waves and the waves made by light in the ordinary way was that the Hertzian waves were many thousand times longer than the waves of light.

Now, Hertz for his early experiments had not available a very sensitive means of using these waves and recording them. He employed a ring of metal with a little joint in it, such as a piece of wire with the two ends almost touching, and he said if the waves came past that loop of wire there would be a tiny spark between the ends. This method was not at all a sensitive method of observing the waves; nevertheless, it was used by Hertz.

At a later date Mr. Branly discovered a new phenomenon which has enabled wireless telegraphy to be carried out at enormous distances. This phenomenon is that if you take any two pieces of metal which touch one another lightly, should a wave come in the direction of these metals a curious effect will be observed For instance, supposing I take two pieces of wire—this is the original experiment as carried out by Hertz—two pieces of ordinary copper wire which have been made somewhat dirty and let them rest against one another, and then connect to them an ordinary electric bell and a battery, that electric bell will not ring, because, if the wires are dirty and touch one another lightly, they will not make what is called a good contact. Now, the primary discovery was that if electric waves fall on a joint of that sort the bell will ring. So that if I can generate an electric wave and get a delicate contact of two wires touching one another lightly, when the waves fall on that contact it will cause the bell to ring. That is the fundamental experiment of wireless telegraphy—the use of two pieces of metal which are not touching sufficiently well to allow the current to flow through them, but which directly you generate any waves will at once send an electric current through them. This experiment is very delicate to carry out, as the least vibration when the two wires are touching will cause them to touch sufficiently firmly to send the current through to ring the bell. In this experiment, as shown by Prof. Lodge at the Royal Institution in 1894, Prof. Lodge succeeded, I believe, in so arranging his apparatus that, when the bell rang, its own vibration was sufficient to stop it ringing again. And then when he sent a second spark the bell again rang, and after a few moments stopped itself. I shall not attempt to perform the experiment to-night of making the bell shake the contact, because in a building like this where there is so much vibration going on it is almost impossible to carry it out successfully. But that experiment was really the fundamental one in the early method of detecting electric waves. Prof. Branly also experimented as to what would happen if he tried to send an electric current through a tube containing metal powder or filings. He found that should an electric wave fall on the tube it would at once render the powder conductive, and you would be able to send an electric current through them.

Before proceeding any further with the modern side of the apparatus, I should like to refer to the early predictions of how you could produce an electric wave. Prof. FitzGerald, in describing the work of Prof. Clerk Maxwell, said that if you could by any means produce a spark between the outside and the inside of a Leyden jar, that ought to produce an electric or, as it is now known, a Hertzian wave. In order, therefore, to produce a wave, firstly, we need a jar or bottle which can be charged with a large quantity of electricity, and we need two knobs, or some other means, by which a spark can pass in order to let the electricity inside the jar flow to the outside coat of the jar. But when the electricity from the inside flows outside, it will flow a little too far—that is to say, a little more will flow out than ought to, and it will swing backwards and forwards between the inside and outside of the jar, and will thus produce a current which will oscillate—that is to say, it will first flow in one direction and then in the other alternately, and it will do this with extreme rapidity. It is quite easy to arrange a jar with wires connected with the outside and the inside in which the electricity will flow first in one direction and then in the other many millions of times in one second. If we can produce this current flowing from the outside to the inside and back again many millions of times in one second, we produce around the wire an electric force first in one direction and then in the other, and we also produce a static force. These are exactly the conditions that Clerk Maxwell set down mathematically as necessary to start an electrical wave in space, or what is known as a Hertzian wave.

I should like to refer to a most remarkable article by Sir William Crookes which appeared in the *Fortnightly Review* in 1892 In this article Sir William Crookes predicted that it would be quite possible to communicate from one place to another by means of electric waves without any wires between the two places, and he predicted that it might become the most important method of telegraphing In 1894 Sir Oliver Lodge gave his well-known lecture at the Royal Institution, at which he showed all Hertz's experiments and a few others. In 1896 Signor Marconi, an Italian engineer, came to this country with an apparatus for signalling at a distance. He took that apparatus to the Post Office. The Post Office officials, and Sir William Preece in particular, were very much impressed with the necessity of being able to signal to a distance without having to lay wires, because they had had great difficulty in putting wires from the stations round the coast to the lightships. It was, therefore, very necessary to be able to communicate with the lightships without using cables. Sir William Preece had been working for many years trying to devise a system to overcome this difficulty, but not with complete success, owing to the conductivity of the sea-water and its effect on the magnetic conductor that was then used. The Post Office, therefore, took up and experimented with Signor Marconi's invention, and in 1897 Sir William Preece gave a lecture in which he described the results which had been obtained. These results were looked upon with a great deal of interest, and the Press took up the matter and wrote leading articles on it from day to day. And from that time to the present the developments have gone on steadily, until from signalling over a distance of two or three miles, as was the case in 1897, Signor Marconi has now succeeded in signalling to America, which is 3,000 miles.

I now propose to show you some of the more modern developments of wireless telegraphy, starting with the original form of apparatus for producing electric waves. In the early days it was proposed to use a Leyden jar to produce the electric waves, but they may be produced by any two bodies that can be charged, and I have here a piece of apparatus which has been lent me by the courtesy of the Post Office, and which is of great historical interest, although it is only about eight or nine years old. In fact, this is the actual oscillator which was used in the early experiments

Digitized by Google

of Signor Marconi when he was working at the Post Office. In order to greatly increase the distance at which signals can be given, it has been found necessary to improve all the apparatus piece by piece. In this work a large number of experimenters have been engaged, and they have succeeded in constructing a great variety of apparatus for producing electric waves, for conducting them and for measuring their length and intensity, and it is largely due to the development of different parts of the apparatus that they have succeeded in telegraphing over such great distances.

One of the first developments in order to produce greater sensibility in the receiving apparatus was the reduction in size of what is called the coherer. Removing the air from the tube and the great reduction in size has resulted in producing a coherer which is extremely sensitive. If you want to signal over great distances you have to collect the electric oscillations, and therefore it is necessary to employ some form of wire to the coherer which will be acted upon by the electric waves, and which will have produced in it an E.M.F. that has a pressure of electricity, and that will cause the coherer to become conductive. For this purpose Signor Marconi connected to the terminals of the coherer a horizontal wire stuck out at each end, which helped to collect the electrical waves. In later experiments he found it much better to connect a vertical wire to one terminal of the coherer, and to connect the other terminal to the earth or to a plate fixed in the earth.

For ordinary telegraphy you want a permanent record. Now, when you come to deal with very sensitive coherers, you cannot put a large current of electricity through them It is therefore necessary to arrange a second circuit, so that the coherer has a small current through it, which can be turned on and off with an ordinary switch which works a bell or a printing apparatus. This switch is technically called a relay. I have a relay here made by Mr. Sullivan, and he tells me that he is able to make a relay which will work with about $\frac{1}{300000}$ part of an ampere. It is necessary to have an apparatus of that sort to print signals. Before showing you actual apparatus in operation, I wish to show you some diagrams of how the wires are usually arranged for producing electrical waves.

The lecturer then illustrated his remarks by a number of experiments, diagrams, and lantern slides, including portraits of Marconi and Hertz, and gave some technical details of the functions and operations of the different parts of the apparatus used in wireless telegraphy. He also described the various kinds of transmitters and receivers used by the different wireless telegraphy companies, and exhibited apparatus lent him by the Lodge-Muirhead Company, by Mr. Sullivan, Mr. G. S Brown, and Mr. Bowron, as well as that lent by the Post Office. The lecturer concluded by describing some of the tests carried out by Mr. J. E. Taylor and himself, under the superintendence of Mr. Gavey, engineer-in-chief to the Post Office, between Howth in Ireland and the cable ship "Monarch," during which tests actual measurements were made not only of the current in the vertical wire at the transmitting station, but also of the very minute currents in the receiving wire. These tests established the relations existing between the strength of the received signal, as well as the distance and the height of the vertical wire and its resistance. He believed that these results would prove of great practical value in designing stations for wireless telegraphy.

CABLES FOR ELECTRIC DISTRIBUTION.

(Specially Contributed.)

The Electrical Exhibition at Olympia affords a good opportunity for reviewing the present practice of cable manufacture and of systems for the distribution of electrical energy. The last electrical exhibition at the Crystal Palace, held in 1892, came at a time when there was a great deal of uncertainty as to the best means of insulating street mains. The use of indiarubber had already been proved unsatisfactory, but it was then still being employed by many engineers. A perusal of Mr. Hamilton Kilgour's book on electrical distribution and the descriptions in it of the systems existing in 1892 is interesting, as showing what was then being done. Thus it is to be noticed that a large variety of street mains with bare copper conductors and porcelain and air insulation were introduced. These have not survived to any considerable extent owing to various causes The space required was considerable, and the systems were hardly practicable enough to meet the conditions which exist under the pavements in a busy town. Of insulated cables the book gives several descriptions, amongst which is one of the original paper-insulated mains used by Mr Ferranti for high-voltage transmission between Deptford and London. These mains may be looked upon as the parents of the paper-insulated cables now so universally employed. Practically every cablemaker exhibiting at Olympia uses paper insulation for their high-tension conductors. The cables vary amongst themselves as to the quality and class of materials employed in manufacture of the paper and in the impregnation of the same. They are all, however, the outcome of Mr. Ferranti's pioneering work at Deptford. The use of this insulation has necessitated lead sheathing, and quite a large portion of distribution cables used to-day are also armoured and then laid direct in the ground.

The type of main laying which has not been altered during the past 13 years is the Callender's solid system. Thus the following is a verbatim extract from p. 352 of the above book, which our readers will see would do as a specification of the same system to-day: "In the Callender solid system of underground electric mains the

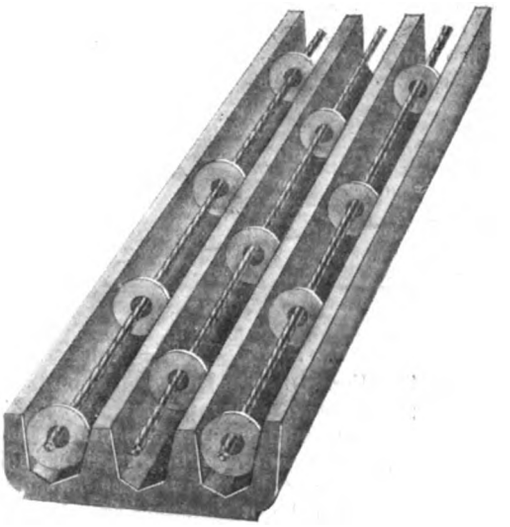

FIG. 1.—"Imperishable" System. Trough showing Conductor in position ready for filling

cables, heavily insulated, are laid in suitable troughs, generally of cast iron, placed in trenches under the street, and the whole of the vacant space in the trough round the cables is run in solid with refined bitumen. All the bitumen employed is genuine natural Trinidad bitumen, free from any admixture of gas, tar, and pitch. The whole forms a solid and compact mass, into which neither gas nor water can possibly penetrate, and which itself forms a very high electrical insulation. There are few substances more durable than this bitumen, and with cables thus embedded there is little probability of any deterioration taking place in mains when once laid, while thorough mechanical protection which is ensured reduces to a minimum the liability of injury from exterior causes. Mains laid on this plan are permanent, and form a sound engineering job. It is, of course, clear that such mains should only be laid when the conditions do not require that the capacity of the cables should be afterwards altered."

Another old idea which, while not successful at the time, is now being revived, is that of Mr. T. Tomlinson's, a description of which may be found on p. 274 of the above-mentioned book. His idea was to construct a concrete trough under the street and to introduce into it bare copper tubes. These were then to be filled up solid with a special composition of asphalt, which was to afford the necessary insulation. The idea of using a tube was to allow of the section of the conductor being increased, as more copper could be drawn in as required. Two firms

Digitized by Google

are showing at Olympia systems similar to this as far as insulation is concerned. The first of these is the Simplified Underground Conductor Company, Limited, who on Stand 107A show a variety of troughings into which bare copper mains can be laid and filled in solid with their special composition.

Another type of system on the same general principle is that known as the imperishable system, exhibited by Messrs. Alexander Duckham and Co. In this, as illustrated in Fig. 1, the troughings are made of reinforced concrete, with a separate way for each main. They are supported on porcelain insulators, and run in solid with a special box compound.

(To be continued.)

THE TRANSMISSION OF POWER BY ALTERNATING CURRENTS.

BY ALFRED STILL, M.I.E.E., A.M.I.C.E.

(Continued from page 454.)

Rise of Pressure at the Distant End of a Long Transmission Line.—A slight modification of the diagram (Fig. 9) will clearly show the well-known effect of a *rise* of pressure occurring at the far end of a line *when the load is very small* provided also that *both self-induction and capacity are present*. We shall still suppose the arrangement to be as shown in Fig. 8, with the one exception that the transformer and load at the receiving end are entirely disconnected. We shall also suppose the capacity and self-induction to be greater than in the previous example, so as to magnify the effect.

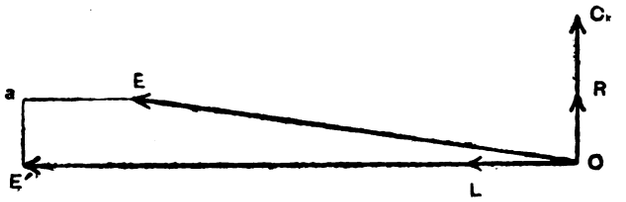

FIG. 10.

Draw O E' in Fig. 10 to represent the pressure at the distant end; then O C_k (at right angles to O E'—in the forward direction—and equal to $2\pi n$ K E') is the capacity current which, under the condition of open circuit at distant end, is also the total current flowing in the wires. We now proceed with the construction exactly as in Fig. 9, making E' *a* (in phase with the current) equal to $C_k \times 2r$, and *a* E (at right angles to the current) equal to $2\pi n \times C_k \times 2$ L. The vector O E, which, it will be seen, is *smaller* than O E', is the necessary pressure at generating end. It will be noted that, if self-induction were absent, the pressure at generating end would be O *a*, which is practically equal in length to O E'; but, since the E.M.F. of self-induction, O L (for this particular state of things) is *in phase with* E' it stands to reason that the necessary pressure at generating end will be *reduced* accordingly.

Rises of pressure at the end of long underground feeders are by no means uncommon, and they may also occur on long-distance overhead lines. Indeed, a rise of 8 per cent. has been observed on a 40-mile 25,000-volt line when the circuit was open at the distant end. It should be mentioned that the pressure rises due to the combined effects of capacity and self-induction are often greater in practice than would be indicated by the construction of a diagram such as Fig. 10. But this diagram is based on the assumption of the E.M.F. wave being a sine curve, and the abnormal effects sometimes met with in practice are almost invariably due to peaked or irregular wave forms. These may lead to enormously increased capacity effects, which, unfortunately, cannot be predetermined with any degree of accuracy. The writer does not see that there can be any insurmountable difficulties in the way of designing alternators to give E.M.F. waves approximating to sine curves; careful attention to the arrangement and shape of the pole-pieces should lead to the desired results. That such a wave form is desirable in nearly all cases there can be little doubt, yet few manufacturers of alternating-current generators appear to have given special consideration to the matter. The essential point to bear in mind is not that the wave should exactly coincide with the theoretical sine curve, but that, *especially on open circuit*, it should be free from ripples or peaks.

With regard to *electrical resonance*, this is generally supposed to be responsible for nearly all unlooked for and, at first sight, unaccountable capacity troubles; but exactly what they mean by resonance, few, if any, electrical engineers are able to explain. There are, no doubt, certain scientists and mathematicians who have a clear understanding of the causes which lead to resonance effects, but they have not yet succeeded in expressing these ideas in popular language. The writer prefers, if possible, to avoid any reference to electrical resonance, because of the indefinite if not erroneous ideas which the expression suggests. It would, however, seem as if every transmission line had a certain natural period of wave oscillation, with the result that, when the periodicity of the supply synchronises with it, abnormal pressure rises may occur. This synchronism might occur not only with a definite alternator speed, but also through ripples or irregularities in the wave form; and this is an additional reason why machines giving sine curve waves under all conditions of load would seem to be the ideal generators for the purpose of power transmission.

TRANSMISSION BY TWO-PHASE ALTERNATING CURRENTS.

Let us first assume, as when dealing with single-phase transmission, that not only the load at the distant end, but also the transmission line are without self-induction or capacity. If we run four conductors as in Fig. 11, keeping the two phases entirely separate, the arrangement resolves itself into the transmission of two distinct single-phase

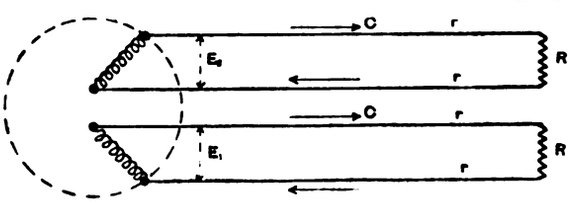

FIG. 11.

currents; and if the load is equal on both sections the total power transmitted will be

$$W = 2 E \times C,$$

or,

$$2 \times C^2 \times (R + 2r),$$

where E = the terminal pressure of each section, and
C = the current in each section.

The pressure lost in transmission will be $2r \times C$, where r is the resistance of a single conductor, and the necessary weight of copper in the conductors for a given pressure drop (or loss of power) will be the same as for a single-phase transmission scheme. It is, however, evident that by combining two of the conductors to form a common return, the transmission of two phase currents can be effected with only three wires, as shown in Fig. 12.

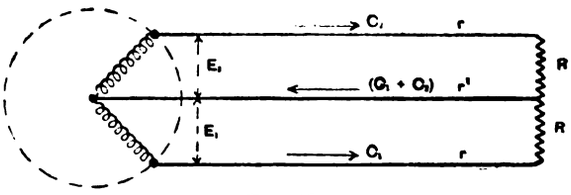

FIG. 12.

The vector diagram for such a system of transmission is very simple *if we can assume the resistance, r', of the common conductor to be negligible*, and it has been drawn in Fig. 13. Here the phase difference of a quarter period between the two E.M.F.'s is represented by E_1 being drawn 90 deg in advance of E_2, and since the circuits are balanced—*i.e.*, since the load is the same as both phases—we may write

$$C_1 = C_2 = \frac{E_1}{r + R} = \frac{E_2}{r + R},$$

and as we are not taking into account either capacity or self-induction, the two currents will be in phase with the respective E.M.F.'s, and the return current in the common

Digitized by Google

conductor will be 45deg. in advance of E_2 and 45deg. behind E_1: its value (owing to O C being the hypothenuse of a right-angled triangle) will be $\sqrt{2}$ times C_1 or C_2.

We shall now see how the problem is somewhat complicated as soon as the common return conductor has appreciable resistance.

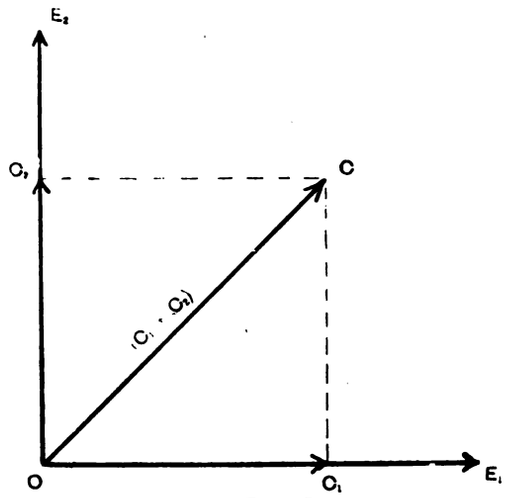

FIG. 13.

For the purpose of drawing the diagram Fig. 14, we may suppose the E.M.F.'s, E_1 and E_2, at generating end to be the same as in the previous diagram, but the pressure drop will be greater, owing to the resistance of the common return, and—for the sake of exaggerating the alteration in the diagram—we shall assume this drop (in the middle wire alone) to be as much as half the impressed voltage—*i.e.*, $\frac{1}{2}$ E_1 or $\frac{1}{2}$ E_2. Owing to the load being balanced and the connections symmetrical, the fact that the middle conductor has appreciable resistance will not alter the phase relation of the total current, which will still be midway between the two E M F.'s, as in Fig 13, and since the component of the E M.F. required to overcome the resistance, r', of the middle conductor must be in phase with this total current, we may draw O a_3 to represent this component in such a direction as to make an angle of 45deg. with O E_1 and O E_2, and of a length equal to one-half of either of these vectors.

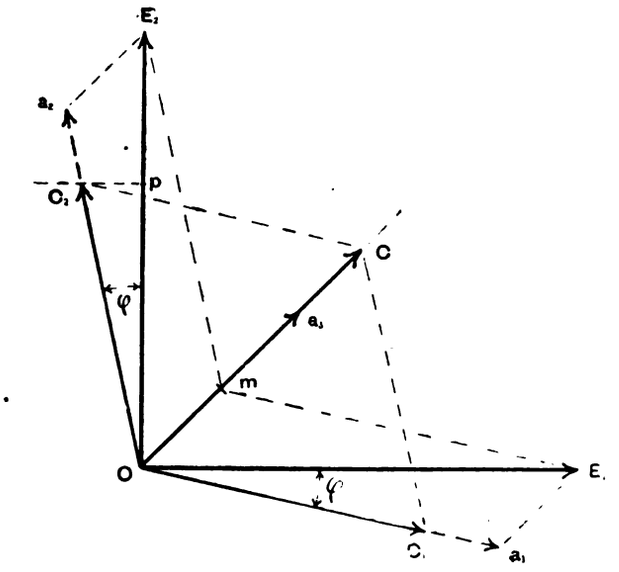

FIG. 14.

Again, on account of the symmetry of the arrangements, half of this component of the necessary total E M F. may be considered as being provided by E_1 and half by E_2. We must, therefore, bisect O a_3 at m, and complete the parallelograms O m E_1 a_1 and O m E_2 a_2, which will give us the E M.F. components, O a_1 and O a_2. These are evidently the components of the total E M F.'s, E_1 and E_2, which are necessary to overcome the resistance, r, of the outer conductor and, R, of the load, and send the two separate currents through this portion of the circuit before they unite to flow back through the common conductor (see Fig. 12). The currents C_1 and C_2 must, of course, be drawn in phase with a_1 and a_2 respectively. As to the magnitude of these currents, this will depend upon the value of $r + R$; but, on the assumption of a given *power* to be transmitted—equal, let us say, to the power transmitted in the arrangement to which Fig 13 applies—the projections of O C_1 and O C_2 on the corresponding E M F. vectors, O E_1 and O E_2, must have a definite value. If the point p in Fig. 14 corresponds to the point C_2 of Fig. 13, we have merely to erect the perpendicular p C_2 to O E_2, and the point C_2, where it meets O a_2, gives us the vector O C_2, representing the current in the outer conductors corresponding to the particular amount of *power* which each phase has to transmit. (The vector O C_1 is obtained in a similar manner, being equal to O C_2 in the case of a balanced load such as we are considering.)

The total current ($C_1 + C_2$) is obtained by compounding C_1 and C_2, and is represented by the vector O C; and we now have all the necessary particulars to enable us to calculate the required section (or resistance) of the lines for a given loss of power in transmission. (It should not be necessary to point out that the resistance, r', of the common conductor $= \frac{O\,a_3}{O\,C}$, while $(r + R) = \frac{O\,a_1}{O\,C_1}$).

The important conclusion to be drawn from the diagram Fig. 14 is that the arrangement of a two-phase transmission line with a common return conductor, although it effects a certain saving in the necessary weight of copper, leads to *an increase of the phase angle between the two currents*. It is true that the displacement is somewhat exaggerated in the diagram, which is based on the assumption of an abnormally large resistance drop, and, in actual practice, the angles ϕ—with a reasonable $C^2 r$ loss, and the same current density in the three wires—would probably never exceed 5deg—that is to say, the phase difference between the currents, at times of full load, might be 100deg. instead of 90deg. As a matter of fact, long-distance transmission by two-phase currents is usually carried out by four wires, partly because of the above objection to the common conductor, but also because there are certain advantages in keeping the two phases entirely distinct. We may, therefore, save ourselves the trouble of constructing further diagrams, on the lines of Fig. 14, but very much more intricate in appearance, which would take into account the effects of self-induction and capacity.

Everything that has been said in connection with single-phase transmission being applicable to the case of two-phase transmission with four wires, there is very little more to be added. It is true that, in addition to the self-induction of the lines, each circuit will have a certain inductive effect upon the other, especially when (as is usually the case) the two circuits are supported by the same set of poles. But, with a reasonable distance between the wires of the two circuits, the effects of mutual induction, even on a long line, are negligible. If necessary, it would be easy to cross the wires of one of the circuits at the middle point of the line, which would practically eliminate these effects.

Self-Induction of Two Phase Line with Common Return.—As the calculation of the *self induction* of a two-phase line with common return may present some difficulties, it is proposed to deal briefly with this question before passing on to the subject of three-phase transmission. In order to simplify the diagram, we shall make the assumption that the middle conductor is without resistance, but that the whole of the resistance of the line is divided equally between the two outer conductors.

In Fig. 15, O E'_1 and O E'_2 are the pressures at the distant or receiving end of the line. There is an angle of 90deg. between these vectors to represent the phase difference of a quarter period. The two currents, C_1 and C_2, which will flow in the outer wires, are shown lagging behind their respective pressures by an angle θ depending upon the power factor of the load. The dotted vector, O C, gives us the magnitude and phase of the resultant current in the common middle conductor, of which the resistance is supposed to be negligible. The drop of pressure due to the resistance of the outer conductor conveying the current C_2 will be O e, but as regards the drop due to self-induction

Digitized by Google

this may be considered as the resultant of two E M.F.'s—the first, O M, calculated on the assumption that the total magnetism in the loop is due to C_2, and the second, O N, calculated on the assumption that the total magnetism in the loop is due to the current, C, in the common conductor. Each component E M F. must evidently be drawn 90deg. behind the current to which it owes its origin, and by compounding these we get O P as the total E M.F. of self-induction. We are now in a position to draw the vector O E_2, representing the pressure at the generating end of the line. It is obtained by adding to O E'_2 the three forces: E'_2 A equal to O e; A B, equal but opposite to O M; and B E_2, equal but opposite to O N. The vector O E_1 for the other phase is obtained in a similar manner.

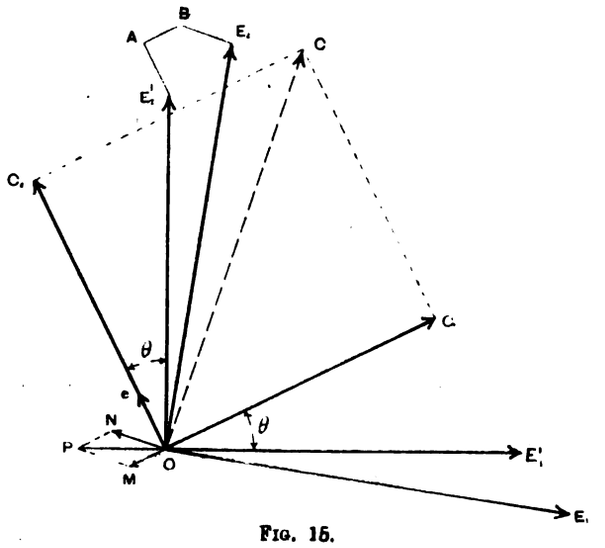

FIG. 15.

With regard to the actual calculation of the lengths O M and O N, it will be remembered that the curve (Fig. 4) gives us the coefficient of self-induction per mile of *single conductor*. The advantage of this will now be apparent, as we have merely to calculate the E M F's on the supposition that each wire forming the loop is producing a magnetic field independently of the other; bearing in mind that the E M F. component, O M, is due to the current, C_2, in one of the wires, while O N is due to a current equal to $C_2 \times \sqrt{2}$ in the other wire, these two E M.F.'s being compounded in the usual way, as indicated in Fig. 15.

TRANSMISSION BY THREE-PHASE ALTERNATING CURRENTS.

We shall again assume, in the first instance, that the line is without self-induction or capacity. If we were to run six separate conductors—*i.e.*, two for each phase—we should merely be transmitting three independent single-phase

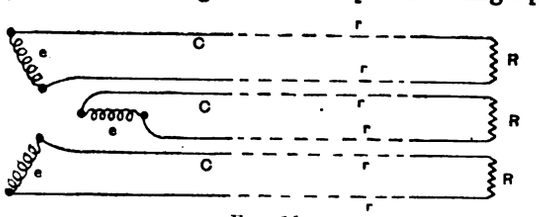

FIG. 16.

currents, the arrangement being as shown in Fig. 16; and if

e = the potential difference at the terminals of each circuit;
C = the current in each wire;
r = the resistance of each wire;
R = the resistance of the "load" on each phase;

then the total power transmitted would be

$$W = 3\,(e \times C),$$

or,

$$W = 3 \times C^2 \times (R + 2r).$$

The pressure lost in transmission would be $2r \times C$, and the total power lost in the lines would be $3 \times C^2 \times 2r$.

Let us now see what is the effect of providing a common return for these three circuits. The arrangement is shown in Fig. 17. The pressure at generating end between the three terminals of the alternator and the common return or neutral point is still e volts, and the total power transmitted is still $W = 3\,(e \times C)$, but, owing to the fact that the sum of the three outgoing currents is zero (seeing that they differ in phase by 120deg, as shown in Fig. 18, and that any one current, such as O B, is exactly equal and opposite to the resultant of the other two currents), there will be no current flowing in the common return conductor, and both pressure drop and $C^2 r$ losses in lines are, therefore, reduced to *one half* of what they were with the arrangement of three separate circuits, the power loss in the lines being now $3\,C^2 r$. This clearly shows how the transmission by three-phase currents is more economical as regards line losses than single-phase transmission. But it must not be overlooked that, in order to obtain a reduction by half of the weight of copper in the lines, the pressure between wires is greater on the three-phase system than on a single-phase system transmitting the same power. Thus, the pressure, E (Fig. 17), between any two of the three transmission wires is equal to $e \times \sqrt{3}$, as shown by the

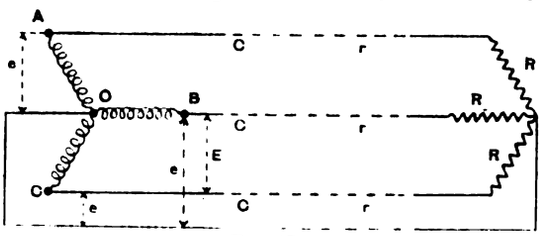

FIG. 17.

diagram Fig. 19. Here the E.M F.'s in the three sections of the alternator windings are represented by O A, O B, and O C, and since the E M.F., E, between any two terminals, such as B and C (Fig. 17), is the resultant of the E M F.'s acting in the two windings, O B and O C, connected in series, we must subtract one of these, O C, from the other, O B. Thus the resultant O E (Fig. 19) is obtained by *adding* to the vector O B an imaginary vector, O C', exactly equal but opposite to O C. This

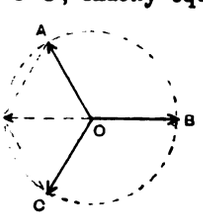

FIG. 18.

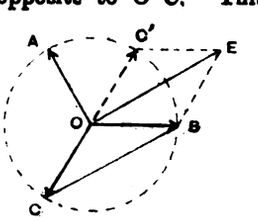

FIG. 19.

resultant is evidently equal and parallel to the line, C B joining the ends of the two vectors O B and O C, and it can be shown to be exactly $\sqrt{3}$ times the length of either of these vectors. We may, therefore, write $E = 1{\cdot}732\,e$

The *power* of a three-phase circuit, which is equal to three times $e \times C$, can evidently also be written

$$W = 3\left(\frac{E}{\sqrt{3}} \times C\right),$$

or,

$$W = \sqrt{3}\,E \times C,$$

where E is the pressure between the wires.

(To be continued.)

PERSONAL.

Mr. J. A. Squire, assistant at Maidenhead electricity works, has resigned.

Mr. E. Edwards has resigned his appointment as general manager of the Gloucester Corporation light railways.

The Loughborough Town Council have increased the salary of their electrical engineer. Mr. W. H. Allen, from £120 to £150 per annum.

The Aberdeen Town Council have awarded Mr. Caird, interim superintendent of the tramways, £100 honorarium for extra duties performed while the Council are without a superintendent.

Mr. Walter J. Bache, M.I E.E, has taken up his work as borough electrical engineer of Cheltenham, and Mr. G. R. White, the assistant engineer, has been requested to take charge of the Gloucester electricity works.

The Rathmines Urban District Council have granted Mr. Pilditch, of the electric light department, an increase of £25 to his salary in connection with his increased responsibilities as electrical engineer, and £25 in connection with his duties at the refuse destructor.

ELECTRIC POWER DISTRIBUTION FOR THE RAND.

BY ROBERT HAMMOND, M.I.C.E.

(*Concluded from page 456.*)

In an electricity works it is obviously far more economical to generate a given number of kilowatt-hours by working at full load throughout the 24 hours than it would be to attain the same output if 90 per cent. of the load came on to the works for three hours per day, and the remaining 10 per cent. were spread over the remaining 21 hours. In the latter case the plant installed would not only be 7·2 times the size of one working on full load the whole 24 hours, but for 21 hours a day it would practically be running idle and most uneconomically. Obviously the 24 hours ideal is rarely attained, and the latter case closely corresponds to the conditions under which many lighting stations are working. The load factor under these conditions would be described as ·1388, or 13·88 per cent. In the supply of power naturally the conditions are more favourable. As has been already pointed out, most of the operations on the Rand are continuous during the 24 hours, and as a result the load factor of the individual mines is often as high as ·5 or ·6. The "load factor" of any works, therefore, furnishes an index of the conditions under which the plant at the central station has to work, and whether it is working at a varying and uneconomical rate or not. The "diversity factor," on the other hand, relates to the maximum load which the works will be called upon to supply at any one time when dealing with a number of consumers whose respective maxima are known.

The demand of all power users must fluctuate to some extent from time to time, and even in kindred industries it is inconceivable that all the consumers would attain their maximum demand at precisely the same moment. Hence the capacity of the generating plant necessary to supply those consumers is not arrived at by adding together all the individual maximum demands. The term "diversity factor" is used to denote the ratio of the maximum load to be supplied by the central power plant to the sum of the individual consumer's maxima. Its value depends, of course, upon the extent to which the various consumers' demands overlap one another.

The writer agrees that in practice it is impossible to obtain a load factor of 100 per cent., but he points out that the greater the number of consumers and the more diverse the purposes for which the power is used, the more will the resultant load on the generating station approach the ideal one shown. A certain degree of overlapping cannot be avoided, but the percentage effect on the total load would be small. The writer instances the load obtained at a tramway generating station. In a small works with but a few cars running the load varies between enormous limits. On a large system, however, the total load is almost constant.

Turning now to the conditions under which a power station for the Rand would have to work, it is evident that a very favourable load factor would be obtainable. As stated above, the load factor of the plant at many of the mines is as high as ·5 or ·6, but, of course, it would be too sanguine to trust that all the consumers' demands would be as favourable. The writer is inclined to think that it would be on the safe side to assume that the average of the consumers' load factors would be 40 per cent., equivalent to an average use of the maximum power for 9·6 hours per day. On the basis of a consumption of 300,000,000 units per annum and a 40 per cent. load factor the sum of the consumers' maximum demands would be 82,200 kw. On the assumption of a diversity factor of 60 per cent. and a 20 per cent. loss in distribution and transformation, a plant capacity at the generating works of 60,000 kw. would be required.

Capital Outlay.—The engineers to whom the carrying out of the scheme was entrusted would have to give very careful consideration to the question whether the generation to the question whether the generators should be steam or gas driven. In designing the power-house for the supply of electric power to the trams, and for the lighting in the future of the city of Johannesburg, the engineers recommended that preference should be given to gas-engines on the ground that electric energy could by their use be generated more cheaply and as efficiently as with steam plant. The writer, therefore, deems it prudent to figure on the more expensive steam plant, thereby providing for the possibility of a reduction upon his figures if the scheme were carried out by the use of gas-driven plant.

Power House.—Dealing, then, with steam generators, provision should be made for seven generating sets, each of a capacity of 10,000 kw., each set being capable of sustaining an emergency overload of 20 per cent. On the assumption that one set would be occasionally laid off for overhaul, there would always be available for active use six sets with a total normal capacity of 60,000 kw., and an overload capacity of 72,000 kw., amply sufficient to cope with the estimated present requirements and the estimated output of 300,000,000 units per annum. The cost of the power-house, including steam generators, boilers, pumps, condensing plant, switchboard, and erection, is estimated at £980,000.

Transmission and Distribution.—The estimate is drawn upon the basis that the primary voltage would be 6,600 volts, the mines within a radius of nine miles of the central station being supplied at that voltage. For the more distant consumers, step-up transformers would be used and energy transmitted at 30,000 volts to transforming sub-stations. Two such sub-stations would be required, one on the East Rand and one on the West Rand. The energy would be transformed down to 6,600 volts, and distributed to consumers at that pressure. For the purpose of the estimate a power factor of 85 per cent. is assumed, bare copper overhead wires used throughout, carried on steel structures. The loss in transmission which has been worked to throughout is about 7 per cent. The 30,000 volt feeders to the east and west sub-stations are each arranged so as to be 50 per cent. in excess of requirements, so as to provide for reserve. The 6,600-volt lines radiating out to consumers are able to transmit the energy with a 7 per cent. loss over five miles, if load is taken off at one end, or a course of 10 miles if tapped off evenly all the way. Ample provision is made in the estimate for the transformers necessary to give consumers, especially those who already have electrical systems at work, a supply at any voltage they may desire. The sum included for the electric lines, transformers, sub-stations, etc., is £340,000.

Water Storage Tank.—In order that the plant may work at full efficiency, an ample supply of condensing water is necessary. Provision is therefore made for a tank to hold 100,000,000 gallons, the sum included for its construction and filling being £300,000.

Land and Roadmaking.—A sum of £60,000 is included under this head. The complete estimate is as follows: power-house, £980,000; electric lines, transformers, sub-stations, £340,000; storage tank, £300,000; land and road-making, £60,000; contingencies, engineering, and supervision fees, etc., £170,000; working capital, £150,000—total, £2,000,000. Which it is suggested might be raised in the form of: 5 per cent. debentures, £660,000; ordinary capital, £1,340,000—total, £2,000,000.

Costs of Working.—These are compiled on the basis of an output of 375,000,000 units, made up as follows: used by consumers, 300,000,000 units; loss in distribution and transformation, 75,000,000 units—total, 375,000,000 units. With a maximum load of 60,000 kw. the resultant load factor would be: the output in units multiplied by 100 divided by the maximum load in kilowatts and the total number of hours in the year—viz,

$$\frac{375\,000\,000 \times 100}{60{,}000 \times 8{,}760} = 71 \text{ per cent.}$$

With such a magnificent load factor as this, very low costs of generation are attainable.

Coal.—As the sets of plant would during the bulk of the 24 hours be running at full load, the consumption of coal should not exceed 4lb. per unit generated. The price is taken at 10s. 6d. per ton of 2,000lb.

Water.—A storage tank is provided for under the capital outlay, containing 100,000,000 gallons. This would be drawn upon for the condensing water, which would be pumped from one spot and returned to the tank at the most

* Paper read before the Engineering Section of the British Association at Johannesburg, Aug. 30.

Digitized by Google

distant spot from the intake. It is estimated that there would be required to supply the loss by evaporation, etc., 1¼ gallons per unit of electrical energy delivered to the mains, and this is estimated to cost 3s. 6d. per 1,000 gallons.

Remaining Items.—These will be seen by referring to the full estimate, as follows:

Costs of Generation and Distribution of 375 000 000 Units per Annum.

Coal on the basis of 4lo. per unit and 10s. 6d. per ton of 2,000lb.		£393,750
Water (to make up for condensing and for boiler feed), 1¼ gallons per unit at 3s. 6d. per 1,000 gallons		82,031
Oil, waste, and stores		3 125
Wages		52,000
Management, rent, rates, insurance, etc.		12,000
Repairs and maintenance, ½ per cent. on capital outlay—viz.	£2 000 000	
Less working capital	150 000	9,250
	1,850,000	
		552 156
Add 5 per cent. for contingencies		27 607
		579,763
Capital charges—5 per cent. on £660,000 debentures and 10 per cent. on £1,340,000 ordinary capital		167,000
Reserve fund—for depreciation and antiquation fund and 2 per cent. on capital outlay on plant		37,000
Total		783 763
Margin to the good		91 237
		£875,000

Revenue.

300,000,000 units delivered to consumers at ·7d. per unit ... £875,000

Financial Results.—It will be seen that on the basis of a payment by the consumers of ·7d. per unit, there would be sufficient profit to provide 5 per cent. on £660,000 of debenture capital and 10 per cent. on £1,340,000 of ordinary capital, after setting aside the sum of £37,000 per annum to a reserve fund to cover the depreciation and antiquation of the plant. It will, I think, be agreed that these figures are sufficiently favourable to support the idea of one central electric station for the Rand; but it will be seen that they are based on the assumption that water storage of 100,000,000 gallons is possible, and that a matter of 470,000,000 gallons of water per annum, or, say, 1,300,000 gallons per day, are available for making up the losses by evaporation. In making-up the estimate of cost of working it is presumed that this quantity of water will be available at a cost of 3s. 6d. per 1,000 gallons. Doubtless, if a good supply of water were available, it could be secured at a lower figure, but the serious question in such quantities at one central spot is to permit of the daily evaporation of so large a quantity. Assuming that the demand from mines on the east of Johannesburg would roughly be double that from the west side, the ideal position for the power-house is about eight miles to the east of Johannesburg. Is water available in that vicinity in sufficient quantity? If not, where can it be obtained, and at what cost? Let us presume for the purpose of illustration that ample water were available at Vereeniging, at a distance of, say, 35 miles from Johannesburg. In this case it would be necessary to add to the estimate of capital expenditure a sum of, say, £80,000 for the construction of a weir dam to provide a reservoir as a stand-by in times of drought, and of the necessary line of pipes for inlet land return to the lower level.

The generating station would be alongside the river, and the whole of the energy would be transformed up to 70,000 volts. The whole 50,000 kw. would be transmitted to a central point in Johannesburg by means of three sets of transmission lines, each consisting of three cables. Six of these cables would be sufficient to transmit the whole 50,000 kw. with a loss of only 6·7 per cent. The other three cables are, therefore, available as spares. In addition to the central transforming station at the Rand to which the trunk lines would be connected, two other sub-stations would be provided, as was the case with the central generating station, one of these being situated on the East Rand and one on the West Rand. Calling these stations A (west), B (central), and C (east), the whole of the energy would be received at B at 70,000 volts, and rather more than one-third of it would be transformed down to 6,600 volts, and this would be distributed to consumers within a radius of about eight miles at that pressure. The remainder of the energy would be transformed down to 30 000 volts, and would be transmitted at that pressure to A and C. Here, again, a further transformation would be made to the distributing pressure at 6,600 volts. The total cost of the trunk feeders and poles, additional transformers, and sub-stations would amount to, on a liberal estimate, £200,000. On the other hand, the outlay of £300,000 on the storage tank would be avoided. There would, of course, be an increase in the cost of the transmission of the energy, but this would be more than compensated for by the lower price of the coal and water at Vereeniging, always presuming that arrangements could be made for the use of the Vaal River.

If such arrangements could be made, the future central power distribution station for the Rand will probably be situated there, and the supply given at ·6d. per unit. The question will then resolve itself into a purely commercial one, and the mine owners throughout the Rand will have to decide whether it will pay them better to draw their supplies from a central station or to combine to use their own electric installations. There is little doubt that those who are at present only using steam power would find an economy in adopting electric power. In this connection it is significant to note that on the north bank of the River Tyne, in spite of coal being available at very low rates, 50,000 h.p. of steam have been displaced by electrical power during the last two years, the supply being drawn from the central power distribution works situated in Newcastle-on-Tyne.

In conclusion, the writer desires to express his great thanks to the engineers and managers of the Rand mines, who so heartily and fully responded to his requests for data as to the present methods. He especially thanks the following: Mr. Wager Bradford, Langlaagte Deep, Limited; Mr. T. P. E. Butt, Randfontein Estates; Mr. H. Y. Clayden, Consolidated Main Reef; Mr. Percy Cazalet, Nourse Deep; Mr. J. Davies, Goldenhuis Deep; Mr. J. A. Dennison, Rand Mines; Mr. P. Fuller, Princess Estate; Mr. M. Ford, Meyer and Charlton; Mr. E. E. Hardach, Knights Deep; Mr. C. E. Hutton, Van Ryn; Mr. T. Johnson, Rose Deep; Mr. H. C. McDonald, Durban Roodepoort; Mr. David T. Morton, Vogelstruis Estates; Mr. C. J. Price, Village Deep; Mr. H. B. Price, Bonanza, Limited; Mr. Frank G. A. Roberts, Witwatersrand Deep; Mr. H. L. Sapte, Consolidated Gold Fields; Mr. H. Ross-Skinner, Durban Roodepoort; Mr. Edward J. Way, Kleinfontein; and Mr. L. Wilms, East Rand. And he only trusts that the arguments that he has induced in this paper will prove convincing to them, and add another step in advance in the methods of working the Rand mines, which methods in the hands of the very able engineers in charge have already merited so much praise throughout the engineering world.

For the following abstract of the discussion we are indebted to the *Transvaal Leader*:

Mr. SIDNEY JENNINGS said one of the important points to be considered was as to whether enough allowance was made for antiquation of plant. It was a matter of pounds, shillings, and pence to the capitalist and to the engineer who advised him. If it could be proved without doubt that a central power station would be vastly more economical, then he thought the capital, although huge, would be forthcoming. He thought the electrical engineer must recognise that capitalists were timid folk, and that they wanted not only estimates which were apparently correct, but some demonstration to prove that their estimates would be borne out in practice. They had on these fields central power stations of very much smaller proportions than the one advocated by Mr. Hammond. The price they received for their power was something like six times the price at which Mr. Hammond estimated it could be delivered on a very large scale. In other words, the Rand Central Electric Works were selling at 4 1d. per unit, whereas Mr. Hammond suggested that on a very large scale it should be generated and sold for 0 7d. per unit. As to electric winding and air compressing by means of electricity, he last year paid a visit to the chief collieries in West Australia and in Belgium, and he was immensely impressed by the power and facility with which electric winding could be applied on these fields. It was again a question of cheapness. There was no doubt, to his mind, that electrical winding could be made easy, and that the handling of a motor was within the

Digitized by Google

range of the ordinary intelligent engine-driver's capacity. In conclusion, he thanked Mr. Hammond for his exceedingly valuable paper.

Mr. G. HENNING said it was easy to find fault with the Rand engineers for not putting larger distribution power into use, but they should remember a few years ago there was no Rand, and plants had to be put down step by step. They should also remember that the work had been restricted, as each particular group had its own interest and its own policy. If there was to be a central plant they should go the whole length, and have the one plant. As regards Mr. Jennings's statements regarding air-compressors, he did not agree. He was quite certain that if Mr. Hammond were to offer them power at the price he mentioned, they would all take his power. They would be very glad to have such a distribution company.

Mr. E. P. RATHBONE pointed out that with the power contralised in the way proposed, if anything went wrong with the centralisation the whole of the mines would be dislocated. Such a company would have to consider the indemnifying of mine owners if such occurrences happened.

Mr. A. SIEMENS said they had heard every speaker say that the real criterion as to whether the thing ought to be introduced or not was, in commercial and industrial matters, the cost. In electricity, where the capital outlay was so very heavy, the charges in interest and antiquation were the main factors in deciding the matter. Mr. Hammond had told them that the load factor in the mines or group of mines as at present constituted was at present very high—·5 or ·6. What would they gain if they made a central power station? Mr. Rathbone had emphasised the danger of putting all their eggs in one basket. He, for one, did not believe that that wonderful economy could be effected simply by increasing the plant to wonderful sizes. He thought, personally, that 2,000-kw. or 3,000-kw. units were big enough, and they were handier. Mr. Hammond quoted Newcastle-on-Tyne, and said that the North-Eastern Railway Company there were taking their supply from the central power station. He (Mr. Siemens) believed they paid ·45d. per unit. He had been over the Liverpool and Southport Electric Railway, and he was told that they generated their electricity for ·33d. per unit. They had placed their station halfway between Liverpool and Southport. In consequence they had hardly any taxes to pay, and got water for nothing. His argument was that everything depended on the cost. It had not been at all proved that that high-power central stations would necessarily be cheaper than smaller stations. If they could make smaller stations with a good load factor of ·6 or ·7, they could get their electricity as cheap as any big station could give it.

Mr. SPENGEL (Rand Central) pointed out that on the Rand they had comparatively modern plant. On some mines particularly the machinery was most modern, and, therefore, the chance of saving much from electric power supply was not quite so favourable. It seemed to him at first sight that the cost of £30 per kilowatt was very small. However, it might possibly be done. The total working costs appeared to be correct, and it might, therefore, be possible to supply from a plant having a capacity of 60,000 kw. at ·6d. But this was based entirely on the assumption of a large load factor, and if he were advising a financier to put up his money, he would say: "If you can guarantee that load factor, and are able to sell up to 60,000 kw., it would be a safe proposition." But what were they going to do until this state was reached? There was probably no mine which would enter into contract with them now for, say, over 1,000 kw., and new mines generally started at 15 kw. or 20 kw. Until the full load was reached the fixed charges per kilowatt would be rather high, and in that he saw a commercial difficulty.

In replying, Mr. HAMMOND said he did not think his estimate of 70 per cent. for the load factor was too high.

The PRESIDENT (Sir C. Scott-Moncrieff) proposed a hearty vote of thanks to the lecturer, hoping that the paper would raise a general discussion in South Africa.

BURNLEY ELECTRICITY ACCOUNTS.

The accounts of the Burnley electricity department for the year ended March 31, 1905, show a total expenditure on capital account to that date of £87,765. Abstracts of the revenue account and balance-sheet are given herewith.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
To generation of electricity	5,632	11	10
Distribution of electricity	542	12	6
Attending and repairs to public lamps	28	9	2
Rents, rates, and taxes	849	9	3
Management expenses, salaries, etc.	1,114	7	1

LEGAL INTELLIGENCE.

THE ELECTRICAL CONSPIRACY CASE.

At the London Guildhall William Leslie, Francis Cheeseman, George Webber, and Richard T. Rosenberg were again charged with being concerned in obtaining goods and money by false pretences to the extent of about £33,000 from various City and provincial firms in connection with the Electrical Accessories Co. After further evidence had been given, the case was again adjourned.

CHARGE OF EMBEZZLEMENT.

Mr. J. W. Eudean, the ex-manager of the Devonport Tramway Co., was brought before the Devonport magistrates last week to answer four charges of embezzlement. It was stated in evidence that Mr. Eudean had issued a number of season-tickets without the authority of the company. He pleaded guilty to two charges, and the two other charges were withdrawn. He was sentenced to six months' imprisonment.

VALUATION OF ELECTRIC WORKS.

At the Valuation Appeal Court, Hawick, the appeal by the Parish Council against the valuation of the Urban Electric Supply Co.'s premises being fixed at £800 was heard. The Council contended that, were the profits of the company taken as the basis, the valuation ought to be at least £1,350 The company submitted that were due allowance made for depreciation of plant and machinery, and for repairs, even £800 was far too much. Mr. Park, assistant assessor, said that the assessor originally valued the works at £877 and the mains at £439—a total of £1 316—but a compromise was made in court. After evidence had been given, the Court unanimously dismissed the appeal. The Council asked that a case be stated, as they proposed to appeal to the Court of Session. This was agreed to.

COMPANIES' MEETINGS AND REPORTS

WILLANS AND ROBINSON.

The ordinary general meeting of this Company was held on Wednesday at Cannon-street Hotel, E.C., Mr. Mark Robinson presiding. Particulars of the report appeared in our last week's issue.

The CHAIRMAN said that in the unanimous opinion of the Board the Company was moving, slowly as yet, but moving towards renewed prosperity in the future. The Company was not poorer in cash by the half-year's trading, except to a small amount. A loss due chiefly to depreciation was not a loss which called for counsels of despair, and it was useful to point them out; but, on the other hand, until the earnings were more than sufficient to cover the natural depreciation of the Company's property, due to lapse of time and other causes, there could be no pretence that the Company was making a profit. The Company's high-speed engine business was, unfortunately, very unprofitable, for prices continued extremely low. On its gas engine business no final judgment could yet be passed. The Company had made some successful engines as regards design and working, and had the best prospects of a technical success, the only question, as he had said before, being whether anyone would pay enough for such engines to make their manufacture profitable. That question could not be answered yet, but there was one unfavourable fact to be reckoned with, and one which had evolved since the Company undertook that branch of its business. The Company took up the gas-engine as a matter of prudence, because the large gas-engine threatened to supplant the large reciprocating steam-engine. The steam-turbine now threatened that result even more seriously, and so, in turn, the Company had taken up the steam-turbine. The success of the steam-turbine was clearly assured, and there seemed no reason to doubt that the Company would play an important part in developing it. A turbine of 1,400 kw. had been running for some months in one of the lighting stations of the Corporation of Glasgow, and the Board believed its running had been entirely satisfactory to the Corporation and its officers. Another turbine of 3 000 kw. was being installed in the same station, and was nearly ready for steaming, and a third, of the same power as the second, was near completion. Four other turbines which the Company had put to work elsewhere had given satisfaction, and the Board might safely say that the Company was fairly embarked in the turbine manufacture on commercial lines, and might look forward with confidence to a satisfactory business, not less important than that it had enjoyed at any previous time. The manufacture of the Diesel engine, to which reference had been made on former occasions, had just been commenced. Queen's Ferry had been referred to in the report. The directors were satisfied that the proper course was being followed there—that was, not to shut it up, but to develop it gradually. Every effort was being made to keep down the working expenses, as well as the cost of manufacture, and in the last some important economies were in view. The new vanadium steel, a speciality of the Queen's Ferry Works, was rapidly taking an important position in industry. Referring to the accounts, the chairman stated that in the Company's prosperous days the directors wisely put back into the business no less than £134,822 of the Company's profits. Not until the loss exceeded that amount—and the Board confidently looked for the Company to be "round the corner" before any such amount was reached—they would have to face an actual loss of capital.

No criticisms being forthcoming, the resolution that the report and accounts be adopted was put to the meeting, and declared carried unanimously.

MERSEY ELECTRIC RAILWAY.

At the half-yearly meeting of this Company, whose report we published last week, Mr. JAS. FALCONER, the chairman, said the increase in the number of passengers was very interesting, having regard to the change from steam to electric traction. The number of passengers carried had steadily increased from 2,844,708 in the second half of 1902 to 4,862,378 in the first half of 1905, an increase of 2,017,670, or 71 per cent. Those were booked passengers, quite distinct from season-ticket holders, and the receipts from season tickets had steadily increased ever since the line was opened for electric traction. They had stopped the issue of second-class tickets, but the first and third had gone on increasing. As the tramway system of Birkenhead did not afford all the facilities which passengers travelling on their line required for getting to and from the stations, the Board had resolved to provide a service of motor 'buses.

A shareholder inquired whether it was possible to diminish the working expenses, as they still stood at a very high figure. He also asked what the proportion was per train mile in the cost of working by steam to electricity.

The CHAIRMAN pointed out that they were giving more than double the service of trains now that they used to give when the line was worked by steam, and the cost was practically the same. The cost per train mile had been enormously reduced. When steam traction was used it amounted to about 1s. 2d. per train mile, whereas to-day it was about 6d.

DICK, KERR, AND CO.

The ordinary general meeting of this Company was held last week, Mr. John Kerr, M.P., presiding. Particulars of the accounts for the past year appeared in our issue of the 28th ult.

The CHAIRMAN, in moving the adoption of the report, stated that efficiency had been maintained, and everything that could make for economy of production had been studied and given effect to. He remarked that it was desirable that the youth of this country should show a higher appreciation of the technical education which was within the grasp of most of them. During the year the Company had been carrying out operations in almost every part of the world, except in the highly protected countries of Europe and America, where they could get no footing, and they expected none. In this connection he was strongly in favour of a mutual preferential tariff. He asked the shareholders to support the board in setting aside the considerable sum of £40,000 for depreciation, as changes in machinery occurred with frequency in these days. Their order-book was fuller than it was last year, but it was a question whether the percentage of profit was as great. The business was expanding in many directions, and if in the near future there should be less to do at home, their foreign connection might more than fill up the gap.

The motion was adopted, and special resolutions were afterwards passed to alter the articles of association.

MEXICO ELECTRIC TRAMWAYS.

At the annual meeting of this Company, whose report we published in our issue of the 22nd ult., the CHAIRMAN (Sir Charles Euan Smith) drew attention to the need of putting more money into the venture in order to make out of it that good return which everyone considered to be possible. The result of his visit to Mexico was a confirmed opinion that they not only had a valuable property out there, but that the country was also in a state of prosperity and advancement. One thing that must make for the general good of all who had business transactions with Mexico was the fact that the Government there had decided on a fixed value for the Mexican dollar. It was proposed in the near future to extend the Company's lines and ramifications, for which there was very ample room, and this would necessitate additional capital. Prominent men in Mexico were interested in the Company, and were assured of its success and of the need of extended working.

Mr. LUDWIG BREITMEYER seconded the motion, which was carried unanimously.

EDISON AND SWAN UNITED ELECTRIC LIGHT.

The report for the year ending June 30, to be submitted on the 12th inst, states that the sum of £47,898. 0s. 2d. has been brought forward from profit and loss account. Interest on debenture stocks has absorbed £18,760. 18s. 4d., £12,000 has been set aside as depreciation on freehold and leasehold property, plant, machinery, and tools; £1,552. 18s. 5d. has been applied in writing down values of stocks; and the sum of £2,677. 3s. 3d. has been reserved on account of bad and doubtful debts. A further sum of £1,000 has been added to the reserve for future stock depreciation. The result as shown in the net revenue account is a credit balance of £11,907. 0s. 2d., to which must be added the sum of £5,302. 2s. 11d. brought forward from the previous year, thus making a total of £17,209. 3s. 1d., out of which the directors recommend the payment of a dividend for the year on the A shares at the rate of 2½ per cent., amounting to £9,586. 19s., leaving a sum of £7,622. 4s. 1d. to be carried forward. During the year £43,947 of this Company's debenture stocks have been purchased and cancelled, resulting in a profit of £6,970. 9s. in addition to that shown in paragraph 2. This amount has been appropriated partially by way of discount on amounts owing by debtors, and partially as a reserve against stock depreciation. Cost of establishing the business, goodwill, etc., £443,451. 8s. 1d., has been brought forward at the figure standing in the last balance-sheet. The freehold and leasehold property, plant, and machinery have also been brought forward at the value stated in the last balance-sheet, with the addition of the amount expended to June 30, 1905, less depreciation charged in net revenue account. There has been expended on capital during the

Digitized by Google

year ending June 30. 1905, £2,395. 16s. 8d. The shares of the Altrincham Electric Supply have been taken at par, as in previous years. This concern continues to show satisfactory progress. Its indebtedness to this Company has been reduced during the year by £3,265. 8s. 6d. The following resolution, or a resolution to the like effect, will be submitted to the meeting, with a view to its subsequent confirmation as a special resolution: "That the capital of the Company be reduced from £961 090, divided into 150,000 A shares of £5 each, 26,436 B shares of £5 each. and 23,564 B shares of £2. 10s. each, to £888,071, divided into 150,000 A shares of £5 each, 25 436 B shares of £5 each, and 23 564 B shares of 5s. each, and that such reduction be effected by cancelling paid-up capital which has been lost, or is unrepresented by available assets, to the extent of £2. 5s. per share on each of the 23 564 B shares which have been issued and are now outstanding, and by reducing the nominal amount of each of such 23,564 B shares to 5s."

CITY OF BUENOS AYRES TRAMWAYS.

At a general meeting of this Company for the purpose of receiving the liquidators' account and fixing their remuneration, it was stated that the transfer of the undertaking to the Anglo-Argentine Tramways Co. had been accomplished most satisfactorily. The sum of 300 guineas was unanimously voted to each of the liquidators as remuneration.

WEST LONDON AND PROVINCIAL ELECTRIC SUPPLY.

The report for the 12 months ending Dec. 31, 1904, states that the earnings of the Company are dependent on the business done by the Chiswick Electricity Supply Corporation, whose shares the Company owns, and the report of the directors with the accounts and balance-sheet of that corporation accompany the present accounts. From these it will be observed that during the year satisfactory progress has been made by the undertakings worked by the corporation. The corporation accounts, after paying interest on debentures and other charges, show a profit balance of £2,673, which the directors propose to apply to the payment of a dividend at the rate of 4½ per cent. on the ordinary shares. This will be paid over to the West London Company, whose accounts herewith show a balance at the credit of the profit and loss acount in the balance-sheet of £1,953. 4s. 4d. The directors propose to apply this amount to the payment of a dividend on the cumulative preference shares at the rate of 6 per cent. per annum for the year ending Dec. 31, 1900.

CHISWICK ELECTRICITY SUPPLY.

The report for the 12 months ended Dec. 31, 1904, states that satisfactory progress has been made during the year. The business of the Corporation shows a steady increase, and to meet this extensions have been made from time to time. During the year £10 937. 10s. 9d. has been expended on capital account for new machinery, mains, etc. At Chiswick at the end of 1904 the equivalent of 29 668 lamps was wired to the mains, as compared with 25 159 at the end of 1903, and at Aberystwyth the equivalent of 11,902 lamps, as compared with 11,286. Chiswick being a rapidly growing district, there is every reason to believe that the rate of progress indicated by these figures will be fully maintained. During the year the capacity of the Chiswick generating station was increased by the addition of a new 500-h.p. generating set. The station can now supply 50 000 lamps connected to the mains, and efforts are being made to get the new machinery well loaded up without delay. The economy effected by the use of the condenser which started working a year ago will be apparent from the accounts. The total profit made by the Corporation for the year amounted to £4,370. 19s. 8d. Out of this sum interest on debentures and loans, amounting to £1,513. 8s. 2d., has been paid £184. 11s. 6d. has been carried to depreciation reserve account, a balance of £2 673 being carried to the credit of profit and loss account. This latter the directors propose to apply to the payment of a dividend on the ordinary shares at the rate of 4½ per cent. per annum for the year.

APPOINTMENTS VACANT.

Premium Pupil, Electricity Works, Canterbury. See advertisement.

Improver, Perth Corporation electricity works. Wages 12s. per week. See advertisement.

Electrical Foreman. Applications to Box P 50, *Electrical Engineer* Office. See advertisement.

Switchboard Attendant. Wages 20s. per week. Applications to Engineer, Electricity Works, Canterbury, by Oct. 14. See advertisement.

Junior Engineers for a company in the Metropolitan district Apply to B. W., *Electrical Engineer* Office. See advertisement in last issue.

Junior Assistant, Aldershot Urban District Council electricity works. Salary £65 per annum. Applications by Oct. 18. See advertisement.

Assistant for electrical estimating department in large switchworks. Applications to Box H 2, *Electrical Engineer* Office. See advertisement in last issue.

Electrical Engineer, West Ham Borough Council. Salary £350 per annum, with annual increments of £50 to £500 per annum. Applications by Oct. 12.

NEW COMPANIES REGISTERED.

New Arrol-Johnston Car Co, Limited.—Capital, £100,000. Object: to carry on the businesses of engineers, electricians, etc. Registered office: Underwood-road, Paisley.

Nelson Patent Lighting Co., Limited.—Capital, £2 000. Object: to adopt an agreement with J. Blakey, J. Carter and T. Rycroft, and to carry on the business of gasfitters, electricians, engineers, manufacturers of and dealers in electricity for motive power and light, etc.

Neophone (1905), Limited.—Capital, £70,000. Object: to acquire from the Neophone Co., Limited, their rights, title, and interest, subject to a royalty in favour of Dr. W. Michaelis, in certain letters patent for improvements relating to sound-producing and recording apparatus. Registered office: 22, Philpot-lane, E.C.

Newport (Mon.) Motor Supply and Garage, Limited.—Capital, £3,000. Object: to carry on the business of motor garage proprietors, mechanical and electrical engineers manufacturers, builders, and repairers of, agents for and dealers in, motorcars and cycles, etc. Registered office: Cambrian-chambers, Cambrian-road, Newport (Mon.).

CONTRACTS FOR ELECTRICAL SUPPLIES.

Paris.—The Post and Telegraphs Department, 13, Rue de Grenelle, require tenders for copper and bronze wire and other telegraph material. Tenders by Oct. 9.

Prestwich (Lancs.).—The Urban District Council invite tenders for the installation of electric light in their Council Offices, Prestwich. Tenders by 12 noon on Oct. 9.

Chantilly.—Tenders are required for motors, pumps, and generators for the service at the reservoir. Particulars appear in the *Journal des travaux publics* (Paris) of July 20. Tenders by Oct. 12.

Madrid.—The Public Works Department require designs for a scheme of electric tramways in the town. Particulars from Direccion General de Obras Publicas, Madrid. Tenders by Nov. 27.

Utrecht.—The Government Railways require tenders for Contracts 215 219—for steel plates, tirefonds, bolts, etc. Specification (1s.) from the Chief of Works and Stores, Morcelse Park, Utrecht. Tenders by Oct. 24.

Paris.—The Colonial Office, 4 rue Jean Nicot, Paris, require tenders for galvanised iron wire for the Indo-China telegraph service. Tenders by Oct. 10. Specification from Inspection Générale des Travaux publics, room No. 146, at above address.

Great Western Railway.—The directors of this company invite tenders for the supply of various stores from Dec. 1 next to Nov. 30, 1906. Specification, with forms of tender, may be obtained at the office of the Stores Superintendent at Swindon. Tenders to Mr. G. K. Mills, secretary, Paddington Station, London, by Oct. 16.

Leeds.—The Guardians invite tenders for the wiring and installation of subway and underground concentric mains for the electric lighting and power for the pump-house and imbecile wards at the workhouse. Send names to Messrs. T. Winn and Sons 84, Albion-street, Leeds, by Oct. 11, when specification and full particulars will be duly forwarded. Each application must be accompanied by a deposit of £2. 2s., which will be returned on receipt of a bona fide tender.

RESULTS OF TENDERS.

Grays (Essex).—The Urban District Council have accepted the tender of H. H. Carter, of Grays, at £485, for extension of the electric lighting station.

Chelmsford.—Two tenders have been received for lighting the public streets and public clock for a period of three or five years from March 25, 1906—viz, from the Chelmsford Electric Lighting Co. and the Chelmsford Gaslight and Coke Co. The Lighting Committee have the tenders under consideration.

Gloucester.—The City Council have accepted the tender of A. Crane for the supply and delivery at the electricity works, during the ensuing six months, such coal as may be required of the kinds mentioned and at the following prices: Wimberry small at 10s 7d., Princess Royal small at 10s. 4d., and Lydbrook small at 10s. 4d. per ton.

Ashton-under-Lyne.—The Electricity Committee have accepted the following tenders for (Section A) one 500-kw. D.C. generator; (B) one water-tube boiler, with superheater, to be worked in conjunction with a refuse destructor; (C) two superheaters for Lancashire boilers: Bellis and Morcom, engine; Dick, Kerr, and Co., dynamo; Babcock and Wilcox, boiler; W. B. Haigh and Co., superheaters.

Accumulators.—The A.B.P. Accumulator Co., Stockton-on-Tees, notify the following new contracts: 54 17 plate S type cells for Portishead; 55 seven-plate S-type cells for Chester; and 54 11-plate S-type sections for Wilmslow, near Manchester. They have also just completed contracts for a number of batteries for Blackpool Winter Gardens, Handsworth Urban District Council, Barry Railway Co., Silksworth Hall, Brompton, Ivybridge, and for the s.y. "Calanthe."

Pembroke (Ireland).—The Electric Lighting Committee of the Pembroke District Council have accepted the following tenders for the extensions of the electricity supply undertaking: Callender's Cable and Construction Co., London, E.C., at £14,624. 18s. 4d., for electricity supply mains; W. Lucy and Co., Oxford, at £1.132. 10s., for arc lamps, pillars, and accessories; Chamberlain and Hookham, Birmingham, at schedule rates, for house meters; Nalder Bros. and Thompson, London, E.C., at £472, for extension of switchboard.

BUSINESS NOTES.

TRACTION.

Lincoln.—The Corporation's newly-electrified trams are expected to be running this month.

Dundee.—Terms "fairly" satisfactory to the tramway employés have been agreed upon.

Bangkok.—Electric tramways were formally inaugurated by the King of Siam on Tuesday.

Portsmouth.—The inhabitants of Milton have appointed a deputation to interview the Corporation relative to an extension.

Southend.—The Town Council are expected to further consider this week the question of extending the tramways along the sea-front to Shoeburyness.

Glasgow.—The receipts on Monday, the 25th ult., constituted a record, the amount being £3,884, which was £560 more than the corresponding day of last year.

Derby.—The receipts for the nine weeks ended Sept. 23 were £27,723. 11s. 1d., an increase of £1,853. 16s. 4d. compared with the corresponding period last year.

Dover.—The new municipal electric tramway service was inaugurated on Monday, the Hon. George Wyndham, M.P., driving the first car. The rails are laid on sleepers.

London County Council.—A public meeting, presided over by the Mayor of Bermondsey, decided to call upon the local M.P.'s to support the County Council's embankment scheme.

West of Fife Trams.—The promoters of this scheme desire certain modifications in the County Council's requirements as to permanent way. The matter has been referred to committee.

Wilmslow.—The proposed scheme for a tramway between Wilmslow and Cheadle was under the consideration of the Wilmslow Council on Monday night. Finally, a resolution approving of the scheme was lost.

Dartford.—In reply to a public deputation, which urged that the laying of the tramways through the centre of the town should be commenced forthwith, the Mayor stated that steps were being taken to expedite matters as much as possible.

Berlin.—The Great Berlin Tramway Co. has unanimously sanctioned a proposal for the concession of the service into an underground system in certain streets where the traffic is particularly heavy. The cost of the change is estimated at £3,000 000.

Ramsgate.—The Board of Trade has fixed Friday, the 13th inst., as the date of the adjourned inquiry into the Ramsgate tramway accident of Aug. 3, when a tram went over the East Cliff. The inquiry was adjourned for the evidence of the driver, who was too severely injured to be available.

Motor 'Buses.—The London and District Motor 'Bus Co. are beginning their first service this week, and all the company's conductors and drivers will be dressed in uniform. The first service will be between Charing Cross and Putney, *viâ* Leicester-square, Piccadilly-circus, Hyde Park-corner, Knightsbridge, Brompton-road, and Fulham-road.

Potteries Electric Traction Co.—At the meeting of the Stoke Town Council last week it was decided to take immediate steps against the Potteries Electric Traction Co. to compel them to carry out their obligations with reference to the alterations to the roadway in Church-street, and as to the making-up of the highway at the Trent Vale light railway extension.

Leeds.—The Corporation have substituted half-mile for two-thirds of a mile stages in connection with ½d. fares, the longer distance being unprofitable. Having regard to the low fares charged over the system, the Corporation consider transfer tickets inadvisable. The Morley Town Council are understood to be negotiating with Leeds for an extension of the latter's system.

Barcelona Tramways.—The company notify that notarial transfers of their concessions have been executed, and that the instalment of £245,000 has been paid to the company. The company have given notice to redeem the 4½ per cent. debenture stock, and have set aside £50,000 to meet the 5 per cent. debentures (1888). Proceedings will in due course be taken for voluntary liquidation.

Lancs and Yorks Railway.—Steam trains will shortly disappear from the Liverpool-Southport section. An electric battery station has just been erected at Hall-road. There are four of the station buildings between Liverpool and Southport, two of which, situated at Hall-road and St. Luke's, are in operation, while others, at Great Howard-street and Freshfield, are nearing completion.

Bournemouth.—The proposal to institute a Sunday service appears to have aroused considerable opposition, and a committee has been appointed, pledged "in the interests and welfare of the borough, to the maintenance of its best asset, a quiet Sunday, earnestly to support at the forthcoming municipal election those candidates who promise to maintain the present six days' service in the borough."

Wednesbury and Darlaston.—After being closed for nearly two years the tramway between Wednesbury and Darlaston was reopened last week for passenger traffic, and the appearance of the electric cars in place of the old steam trams evidently gave general satisfaction. A through service is in operation between Darlaston and Handsworth. Arrangements to reopen the Dudley section are being proceeded with.

South Shields.—At the meeting of the Tramways Committee the town clerk reported that replies had been received from 37 tramway undertakers, of whom 24 have appointed an independent official as tramways manager, and 13 combine the managership with the office of electrical engineer. The committee, after a long debate, decided by a majority of seven to five to adhere to their former decision to recommend the Corporation to combine the two offices.

Heywood.—The work of reconstructing the tram track is now proceeding steadily towards the centre of the town. From Heap Bridge to Boohole Farm the track is practically completed, but there is a break from the farm to the Towler Inn, where the new lines require laying. From the Towler Inn to the Brunswick Hotel the old track has been lifted and the new lines laid, and the paving has been finished up to the neighbourhood of Wrigley Brook.

Wemyss.—At a meeting of the Kirkcaldy District Committee a letter was submitted from Mr. Sellon, the engineer, suggesting that a meeting should be arranged with him for the purpose of agreeing to certain details, including accommodation for road scrapings, in connection with the Wemyss tramway scheme. Councillor Prentice thought the Roads Committee should send their suggestions to Mr. Sellon, and if he could not agree to them they could meet him and discuss the matter. This was agreed to.

Newcastle.—The total revenue of the Corporation tramways in the past year amounted to £197 493, and after meeting working expenses the gross profits are £71.155. The net balance, after providing for various charges, is £9 954. The number of car miles run is 4 326 152, and the passengers numbered 43 069 934. The Sunday traffic realised £18,910, an average of £356 per day. The weekday traffic was pretty uniform, but the average receipts on Saturdays were £838. The Newburn Urban District Council have decided to approach the Corporation with a view to the Scotswood line being extended.

Fatality.—At a coroner's enquiry held on Monday into the circumstances attending the death of a child named Selina Phillips, who was knocked down by a tramcar and killed, a witness stated that the car struck her down, and he saw her on the lifeguard. He ran alongside and tried to get her by the foot, but she rolled off and under the lifeguard. His opinion was that the driver could not possibly have seen her approach, as she was on the blind side of the car. It was a pure accident, and the driver did all he could to avert it. The jury returned a verdict of "Accidental death," and added a rider that no blame was attributable to anyone.

Mitcham Light Railways.—Committees of the Croydon Rural District Council and the Carshalton Urban District Council have decided, as the result of a joint conference, to recommend that the British Electric Traction Co. be required to provide a wood-paved track throughout the route in the two districts; that in all cases where the width of the carriageway between the outer rail and the kerb was less than 9ft. 6in. the company should be required to wood pave the whole width of such carriageway; and that the cable or feeders should be laid under track. Also that the two authorities should consult together before approving the designs of standards and other details connected with the construction of the lines.

Belfast.—Terms have been arranged for the widening of Shore-road in connection with the reconstruction of the trams. The advertising contract has been let for five years at £2,500 per annum. The overhead equipment is almost complete, but it will be a little time before the power-house is ready. Probably the system will be in operation by the middle of next month. In regard to the delay in the work of reconstruction, the contractors, Messrs J. G. White and Co., state that if the contract is completed within the specified nine months it will constitute a record considering the size of the undertaking, but they have been handicapped by material not being ready. They intimate that they will be prepared to treat any claim arising through the delay in an equitable spirit.

Cost of Tramway Accidents.—A special report just issued compares Sheffield, Leeds, Manchester, Bradford, and Glasgow in regard to accidents. At Sheffield it was found that in the year 1904 1,722 accidents of all kinds happened with a car mileage of 5 997,063, 315 claims were made, and £470 was paid for compensation. In Bradford for the year ended March 31, 1905 1,739 accidents occurred 238 claims were made, and £4,600 was paid in compensation, with a car mileage of 5 053,392. In Leeds £2 000 was paid on a car mileage of 7,044 745 during the same 12 months. At Glasgow £18 000 per annum is paid in insurance against third-party risks; and in Manchester £11.000 was paid for the last 12 months as claims with a car mileage of 13,759,071.

Hanley.—At the meeting of the Town Council the following report of the Works Committee was submitted: "The extension of the Providence-square tramway along Chell-street has been completed, and there only remains to be put in a passing place loop at the junction of Leonard-road. The work of doubling the Broad-street tramway between Victoria-square and Shelton Church has made good progress. The section between Queen-street and Victoria-square will next be taken in hand, and the few objections that have been made will be met by adjusting the kerbs a few inches in the short length between Oxford-street and Sun-street. Objections have been lodged with respect to the narrow part of Snow-hill, but hopes are entertained that terms will be made satisfactory to the owners."

Tipton.—It is gratifying to learn that the Town Council and the South Staffordshire Tramways (Lessee) Co. have now finally agreed upon terms which are as follows: The company undertake within three months from the sealing of the agreement to electrify the line between Dudley and the Bulls Head Inn, Princes End, and within the same period to reconstruct and electrify the tramway from Wednesbury boundary to the Oaker Hill railway station. The intermediate portion where the mining subsidences are now taking place was to be electrified and reconstructed within 18 months from the sealing of the agreement, unless the Council, in their wisdom, see fit to extend that time. In addition, the company undertake to pay to the Council £150 for the watering of the track up to April 3 next, the sum to be paid in advance. The company also agree to pay the sum of £110 per annum, which sum was to be paid in April.

Digitized by Google

Bradford.—After an inquiry into the general administration of the tramways department lasting over six months, the special committee of the Tramways Committee have now issued their report. The inquiry was instituted at the express wish of the manager (Mr. C. J. Spencer) himself, in consequence of certain criticisms which had been levelled at his management. The result is a complete vindication of Mr. Spencer's administration, for the committee, after a careful and detailed investigation, and a comparison with other large tramways, unanimously report that the Bradford tramways compare favourably, both as regards working and organisation, with any other large system in the country. The accounts, both as regards income and expenditure, they find are satisfactory when compared with the accounts of similar systems and taking the local circumstances into consideration.

Falkirk.—At the meeting of the Town Council on Monday the dispute between the Council and the Scottish Central Electric Lighting Co. as to the supply of power for the trams about to be opened in the burgh, was discussed. This has now been settled by agreement, under which the electric power company pay the Council the sum of £100 towards their legal and other expenses, and the sum of £30 per annum. The tramway system will be inaugurated within the next few days. The company are at present restricting the cars to 18. Of that number 15 have already been completed. The cars, which have been made in France, are of the double-decked type, and have a holding capacity for 50 passengers. The high-tension supply of 3 000 volts is transmitted to the sub-station, where it is converted to a pressure of 500 volts, which is the line voltage. The contractors for the entire undertaking are Messrs. Bruce Peebles and Co.

Collision.—At the Hyde Borough Police Court last week Thomas Edwards, a car driver, of Stalybridge, was charged with not bringing his tramcar to a standstill to avoid impending danger in Mottram road. A witness stated that he was riding a horse up Mottram-road, towards the arches; he had a halter on the horse, and the rope was in its mouth. He was proceeding up the centre of the road and saw a tramcar coming in the opposite direction. He tried to take his horse out of the tram track, but there was some water on the roadside and the horse would not face it. Witness then shouted two or three times to the car driver to pull up, but he did not do so. The car dashed into witness's horse, and witness was thrown through the front window of the car. His horse died shortly after the accident. Witness's head was badly cut, and he was not able to follow his work properly yet. The car was coming at a furious speed. He shouted first time when the car was about 50 yards away. For the defence it was contended that the occurrence was quite accidental, and it was stated that defendant bore a good character. Finally, the Bench imposed a fine of 5s.

Torquay.—At the meeting of the Town Council on Tuesday, the town clerk reported having written to the Dolter Electric Traction Co conveying the resolution of the last meeting of the Council that they would only approve of the suggested alterations of tramway routes provided the company relieved the Council of their obligation under their agreement in the event of the Council failing to obtain the consent of the Local Government Board to the proposed loan enabling them to supply the current for working the trams. In their reply, the company stated that the resolution could not be entertained. "The directors," the letter proceeded, "had gone considerably out of their way to assist the Council in the very awkward position in which they had been placed in regard to their proposed new electricity works. It was quite clear under the Act that the Council had to supply the current, but where they supplied the current from was of no moment to the company." The company would now act strictly in accordance with the terms of the Act. After some discussion the matter was referred to committee. The Council have rejected the company's application for leave to lay a line along the sea-front, æsthetic considerations being the reason.

Preston.—The Corporation's official booklet describing the history of the tramway system contains some interesting information. The actual reconstruction of the tramways for electric traction, with standard gauge instead of the 5ft. 6in. gauge used with the horse trams, was commenced on the expiration of the lease to Messrs. Harding and Co., at the end of 1903. Two routes were opened for service in the following June, and in January of this year an extension to the Bowling green Inn was completed. The extent of the system is 10 54 route miles, partly double and partly single track, this work and the overhead equipment being carried out by Messrs. Dick, Kerr, and Co. The Corporation's generating station takes a supply of steam from the refuse destructor. Two Lancashire boilers are at present installed in the boiler-house, and the engine-room contains two 300 kw. Dick-Kerr compound-wound generators, while there is accommodation for another 500 kw. set. The engines are of the horizontal cross-compound type, built by Messrs. Cole, Marchent, and Morley, of Bradford. Each generating set is specially designed to run for two hours on a 25 per cent. overload, and a momentary overload of 50 per cent. above the normal. Official tests of the plant showed the consumption to be 12 25lb. steam per indicated horse-power, and 19 5 lb. steam per kilowatt-hour measured at the terminals of the generators, the combined efficiency of the engine and generator being 85 per cent. The cars were built by the Electric Railway and Tramway Carriage Works, of Preston, and 26 of them are mounted on Brill single trucks with 30 in. steel-tyred wheels, the wheel base being 5ft. For the overhead equipment, span and side bracket construction was adopted. Altogether Mr. W. H. Tittensor, the engineer and manager, has charge of an excellent system.

New American Electric Railway.—A Pittsburg correspondent of the *Times* writes that the Spokane and Iceland Railroad, which runs for 150 miles through a fairly well-developed part of the State of Washington, is to be exclusively equipped for that length with electric power for traction purposes. Steam is to be barred out from any portion of the line, though for the ordinary interchange of passenger and goods traffic the line will be operated to connect with other steam railways. The step is regarded as notable in that the railroad mentioned is the first to decide upon electricity as the sole tractive power. In the construction of the line, however, there appears at first to have been no leaning towards electrical equipment, steam services being contemplated, until a difficulty arose in the high cost of coal in the part of Washington through which the line is to run. Thereupon a standard electric railway with standard equipment throughout was determined on, and the Westinghouse Electric and Manufacturing Co. has been awarded the contract. The single-phase alternating-current system is to be adopted, it being regarded as the most economical for long-distance transmission of power and as dispensing with sub-power stations, while energy is to be generated from a large water-power plant near Spokane. The trolley system is to be used for operating the locomotives, and the one power-house only which the single-phase system of current renders possible will suffice for general traction and shunting purposes, for the lighting and heating of the trains and stations, and for supplying power to the company's works. The initial cost of the work is named at £100,000. The correspondent remarks that the contract is significant in view of the tenacious clinging to steam power by the ordinary American railways and the consequent retarded efforts of electricity to obtain any real footing hitherto.

Croydon.—In reference to our note last week, the following is the text of the terms offered by the British Electric Traction Co. for a renewal of the lease: (1) An increased yearly payment of ½ per cent. on the expenditure for the time being by the Corporation in connection with the tramways—*i.e.*, a yearly payment at the rate of 7 per cent. in place of 6½ per cent. as provided in the present lease. As the expenditure by the Corporation as at Dec 31 last amounted to £237 512. 8s. 10d., the increased percentage represents an additional yearly payment of £1.187. 11s. 4d. (2) An increased yearly payment in respect to road repairs of £100 per mile where the road is paved with wood, and £50 per mile where the road is paved with any other material, for each mile of single track, and of £200 per mile where the road is paved with wood, and £125 per mile where the road is paved with any other material, for each mile of double track. The scale fixed in the present lease is £100 per annum per mile of route, and the yearly payment amounts to £1,076. 19s. 6d. The increased scale represents an additional yearly payment of £1,732. 9s. (3) A farther yearly sum equal to 25 per cent. of the net profit realised from the working of the leased lines, such profit to be arrived at after charging 7 per cent. on the capital employed in the working of the lines, other than that provided by the Corporation, such as the cost of the additional cars provided by us. (4) Electrical energy to be supplied by the Corporation for the working of the leased lines, and for lighting purposes at the price fixed in the present lease—viz., 2d. per Board of Trade unit. (5) Tramway No 20, which is to be constructed by the Corporation under the provisions of the Act of 1902, and the further extensions of the Corporation's tramways for which the Corporation have recently obtained the sanction of Parliament, if and when the Corporation construct the same, to be leased on the same terms and conditions as the existing tramways, and the lease to be coterminous. (6) The Corporation to be entitled to inspect the books and accounts of the working of the leased tramways for the purpose of ascertaining the amount of any payment to be made to the Corporation under paragraph 3 hereof. (7) The new lease to be for the term of 21 years from June 1, 1906, determinable at the end of seven or 14 years by six months' previous notice in writing to be given by either side. The company allude to the fact that they have obtained powers for constructing a system in Mitcham, and point out the advantages to be derived from working the connected lines under one management.

LIGHTING AND GENERAL.

Leek.—Mr. Kenneth Faulkner has been admitted as pupil to the electrical engineer.

Sutton Coldfield.—Sanction has been received to the borrowing of £8.000 for electricity purposes.

Eastbourne.—The Corporation are about to lay cables for the electric lighting of Hampden Park and Willingdon.

Dundee Telephonists.—The Women's Trade Union League have recently formed a local branch of telephone operators.

Eastern Extension Telegraph Co.—The directors have declared an interim dividend for the quarter ended June 30 last of 2s. 6d. per share.

Gloucester.—Sanction has been received to borrow £11.610 for the purposes of the electricity undertaking (extension of buildings and plant).

Stirling.—After investigation, the recent breakdown has been found to be due to an injury to the armoured cable caused by a blow from a pickaxe.

Reuter's Telegram Co.—The directors have declared an interim dividend at the rate of 5 per cent. per annum for the half-year ended June 30 last.

Award.—The jury at the Liége Exhibition has give the Grand Prix to Marconi's Wireless Telegraph Co. for their exhibit of wireless telegraph apparatus.

Edison and Swan United Electric Light Co.—The directors recommend a dividend for the year ended June 30 last of 2½ per cent. on the "A" shares.

Kettering.—The Kettering Working Men's Club is now lighted by electricity. Messrs. Thompson and Co. were the contractors, and the cost was about £105.

Agency.—The British Johns-Manville Co. have been appointed sole agents for the McGillivray system of emergency lighting for cars, trains, and public buildings.

Digitized by Google

Accrington.—The units delivered for week ending Sept. 16 were 7,241, as compared with 4,200 units for corresponding week last year, an increase of 3 041 units, or 72 per cent.

Carrickfergus.—The Lighting Committee have been instructed to make inquiries as to the best means of lighting the town, and find out the cost of an electric plant or new gas plant.

Portsmouth.—The Horndean Light Railway Company have decided to generate their own current and to run a 20 minutes' service from Cosham to Horndean during the winter months.

Salford.—The Council have agreed to allow power consumers (from Jan. 1) to use 15 per cent. of their consumption of electric current for lighting purposes at the power rate.

Direct United States Cable Co.—The directors have resolved upon the payment of an interim dividend of 3s. per share, being at the rate of 3 per cent. per annum, for the quarter ended Sept. 30, 1905

Competition.—A competition of electric lighting and heating apparatus is being opened in connection with an exhibition to be held between Oct. 15 and Nov. 15 under the auspices of *Le Batiment*, a Paris journal.

Islington.—An estimate of £80, the cost of providing and laying the necessary length of low-tension distributing main, to meet an application for a supply of electricity for power purposes, has been approved.

Worksop.—Sanction has been received to a loan of £3 000 for electric light purposes (without an inquiry). The period of 16 years has been fixed for repayment, and an extension to 25 years is being asked for.

South Metropolitan Electric Light and Power Co.—The warrants for the payment of the interest on the 4½ per cent. first mortgage debenture stock of this company, payable on Oct. 1, have been posted.

Kensington.—The Brompton and Kensington Electricity Supply Co. are distributing circulars among their customers in Kensington stating that for the purpose of power, heating, and cooking electricity can now be obtained at the rate of 1d. per unit.

Gomersal.—An application of the Yorkshire Electrical Distribution for the Council's assent to their application for a provisional order authorising them to supply electrical energy at Gomersal will come before a special meeting of the Council shortly.

Dunfermline.—The Corporation and the Fife Electric Power Co. are still negotiating, but the Town Council Committee at present decline to agree to guarantee a maximum quantity of 50,000 units being taken for the first year at the rate of 1⅞d. per unit.

Hammersmith.—The premises of 18 additional consumers, representing a maximum of 378 8-c.p. lamps, have been connected to the mains, and seven consumers have been disconnected, the present number of consumers taking current from the mains being 1,661.

Spanish Cables.—As it is considered impossible to further repair the Canaries cable the Minister of the Interior will propose to the Chamber of Deputies the laying of a new cable. He will likewise propose the laying of a new cable between Spain and North Africa.

Cardiff.—With regard to telephones, tell-tales, fire-alarms, and electric bells at the new asylum at Whitchurch, it has been decided that firms named by the architects with any others suggested by the borough electrical engineer should be asked to tender for the work.

New Address.—The offices of the Midland Electric Corporation for Power Distribution, Limited (J. Hardie McLean, M.I.E.E., general manager and engineer), have been removed from 73, Lichfield-street Wolverhampton, to Colmore House, Waterloo-street, Birmingham.

Falkirk.—The Council have decided to reduce the price of electricity for power purposes to 2d. per unit for the first hour per day of maximum demand, 1½d. for the next two hours, and 1d. per unit thereafter, but with a minimum charge of 40s. per annum. The new rates come into force with the January term.

Bruce Peebles and Co.—An interim dividend has been paid on the original issue of the preference shares at the rate of 6 per cent. per annum for the half year to June 30, 1905, and on the recent new issue of preference shares at the rate of 6 per cent. per annum for the period ending June 30, 1905.

Maidenhead.—Mains are to be laid to Upper Taplow. The following prices have been agreed to in connection with a prospective consumer—namely: for the first 10,000 units per annum, 2d. per unit; for the second 10 000 units per annum, 1½d. per unit; and any further consumption at 1¼d. per unit.

Whitby.—An electrical exhibition is being held with the object of popularising the light and promoting the use of electricity in all its branches in the town. The arrangements were made by Mr. L. H. King, electrical engineer to the Whitby Urban District Council, assisted by Mr. J. Hawes, the Council's assistant electrical engineer.

Brighton.—The ratepayers' association have passed a resolution to the effect that, in view of the action taken by the Postmaster-General and the inconvenience caused to traders by a dual system of telephones, the ratepayers' federation should urge upon the Council the necessity of commencing negotiations for the disposal of the municipal undertaking.

Hull.—The Electric Lighting Committee have decided to lay the mains in Victoria-avenue at an estimated cost of £140. The electrical engineer, Mr. Bell, has been asked to report upon the advisability of laying a cable to St. Andrew's Dock. The agreement which had been prepared for the hiring of electric motors from the Corporation has been approved.

London Gazette.—The partnership between Edwin C. Wallace and E. H. Watson, electrical engineers, 36, Trinity-street, Leeds, has been dissolved by mutual consent. The last day for receiving proofs in the estate of Alexander Holland, electrical engineer, trading as the Electrical and Mechanical Engineering Co. at 13, Bridgwater-street, Farnworth, Lancs., is Oct. 14.

New Firms.—Mr. H. S. Meyer, M.I.E.E., who for the last five years has been the British Thomson-Houston Co.'s chief designing and consulting engineer for alternating-current work, has resigned his position to open an office in London as electrical expert and advising engineer. Mr. John E. Raworth has opened an office at the Queen Anne's-chambers, Westminster, as a patent agent.

Stock Exchange.—The Stock Exchange Committee have appointed Oct. 11 special settling day for Babcock and Wilcox's further issue of 270 000 ordinary shares of £1 each, Nos. 530,001 to 800,000, and have ordered the said securities to be quoted in the official list. The committee have also been asked to allow the Indian Electric Supply and Traction Co.'s £125 000 6 per cent. construction debenture stock to be quoted in the official list.

New Atlantic Cable.—A Reuter telegram says the cable steamer "Colonia," which left Canso on Sept. 23 paying out the Commercial Cable Co.'s new Atlantic cable, arrived at 6 p.m. on Tuesday at the point 187 miles from the Irish coast, where she has to make her final splice between her ocean cable and the cable laid westward from Ireland by the steamer "Cambria" in June last. This makes the fifth Atlantic cable laid by the Commercial Co.

King's Norton.—A special meeting of the Council will be held to consider the Electric Lighting Committee's recommendation that they should be authorised to continue the negotiations with Callender's Cable and Construction Co., Belliss and Morcom, and the Electric Construction Co. as to the proposed establishment of an undertaking under the electric lighting order, 1898, and to settle with them the terms of the agreements to be entered into by the Council with the proposed new company.

York.—A scheme for lighting Gillygate, Castlegate, Fishergate, and Fulford-road (as far as the barracks) with electricity in place of gas will come before the next meeting of the Lighting Committee. The electric mains for this scheme have already been laid, and it is proposed to use enclosed arc lamps. A scheme for converting the gas lamps in Scarcroft-road and Bishopthorpe-road (as far as main extends) into incandescent electric of the same candle-power as the present gas lamps is also under consideration.

Derby.—The Electric Lighting Committee in their last report recommend a further reduction in the sliding scale of charges for the supply of electricity by ¼d. on each item, as follows: not exceeding 2 000 units per quarter, 4½d.; over 2,000 units and not exceeding 3,000, 4¼d.; over 3,000 and not exceeding 4,000, 4d.; all quantities over 4,000 units per quarter, 3¾d.; and to reduce the charges on the maximum demand system from 6d. for the first hour and 3d. afterwards to 6d. for the first hour and 2½d. afterwards.

St. Marylebone.—It is anticipated that the whole of the 6,000 consumers in the St. Marylebone district will have been transferred from the system of the Metropolitan Electric Supply Co. to that of the Borough Council's by the beginning of 1906. The whole of the district at the present time is being supplied with both continuous and alternating current at pressures varying from 50 to 240 volts. The whole of the consumers' installations have been overhauled, and the conversion of the pressure to 240 volts continuous current is being proceeded with as rapidly as possible.

Buncrana.—The Buncrana Electric Supply Co.'s undertaking was opened yesterday. The station engineer-in-charge is Mr. John K. Swan. In connection with the carrying out of the contract the following were contractors: engineers—hydraulic and power, Mr. James F. Maryon, C.E., London; electrical, Mr. Lewis J. Lawless, A.I.E.E., Dublin; engines, turbines and steel-pipe line supplied by James Gordon and Co., London; dynamos, motor and balancer set by Crompton and Co., Chelmsford; switchboard and resistances by General Electric Co., Witton; power-house buildings erected by Mr. Humphrey Campbell, Buncrana. The engine-room contains two direct-current Leffel water-turbines and continuous-current shunt-wound generators. The turbines are designed to develop 65 b.h.p. on the coupling when working under a head of about 60 ft., the water being conveyed from the upper level by means of riveted steel piping of 28in. internal diameter. The dynamos are of Messrs. Crompton's four-pole type, having self-oiling ring bearings and carbon brushes. The sets run at a speed of 780 r.p.m., and one of these duplicate sets will be sufficient for dealing with the present lighting requirements, the second being held in reserve for immediate use in the event of anything going wrong with the other turbine or generator. The equipment also comprises a gas-engine capable of working up to 75 b.h.p., and a third electric generator arranged for belt driving from the gas-engine or mill turbine. The engine is by Messrs. Grice, of Birmingham, arranged to work with suction gas supplied from a special producer plant contained in a compartment adjoining the engine-room. The distribution of the electric energy for the public and private lighting is by means of bare copper cables, carried overhead on poles spaced about 130ft. apart. The service is carried out on the three-wire system at 235 volts between either mains and the neutral conductor, the maximum voltage between the outside wires being 470. An independent service is provided for the street lamps controlled directly from the power-house. There are five arc lamps, besides a large number of smaller lamps, varying in power from 80 to 50 candles each, for the less important positions. The street lamps are in all cases enclosed in watertight lanterns, mounted on brackets fixed to the poles carrying the overhead cables, and each lamp will be protected by a fuse to cut out the fitting in case of any fault in the lamp sockets or connections. House connections are made by means of overhead service lines leading directly from the nearest connecting point to insulators fixed on the consumers' premises, and connection inside each house is carried out by means of special cable connecting the source of supply with the wiring contractor's cables.

Digitized by Google

Handsworth.—The formal opening of the electric lighting station in Piers-road will take place on Monday, when Sir A. B. W. Kennedy, the consulting engineer of the works, will give an account of the undertaking. Dr. A. T. Holdsworth, chairman of the Council, will unveil a bronze tablet fixed to the front of the building recording the date of opening. Afterwards Councillor Fred Tibbitts, chairman of the Parliamentary and Electric Supply Committee, will unlock the door of the principal entrance and declare the building open, and Mrs. Tibbitts will set the machinery in motion.

Dudley.—The electrical undertaking has now been running about five years. It provides current for the tramways, for several factories, and for the lighting of the main thoroughfares of the town and of many private residences and shops. The works and distributing plant has cost nearly £80,000. After provision had been made for principal and interest, there has remained every year a profit of a few hundreds of pounds, which have been placed to a reserve fund. An inquiry has been held into the application of the Town Council for sanction to borrow £21,000 for purposes of their electrical undertaking.

Southwark.—The Electric Light Committee reported at the last meeting of the Borough Council on a communication from the Electric Contractors' Association on the powers sought to be given borough councils to wire and fit consumers' premises for the use of electrical energy. As our readers are aware, the clause giving such powers was struck out of the County Council (General Powers) Bill last session by the House of Lords Committee after having passed the House of Commons. The Council adopted a recommendation that the County Council be urged to insert the clause in their next General Powers Bill.

Aston.—The second anniversary of the opening of the electric power station was celebrated last week. At a dinner the Chairman of the Electricity Committee (Councillor A. E. Godrich) said that whilst the number of units sold in August, 1904, was 78,432, it had grown to 118,616 units in August of the present year. The price they charged for lighting purposes was lower than any other place in the country. They charged for lighting purposes a maximum of 3¾d. per unit, and a minimum of 2½d. per unit, less 5 per cent. if the amount was paid promptly. Subject to the approval of both Councils, they had arranged to supply electrical energy to Erdington.

Elstead.—The Hambledon Rural District Council have been discussing a proposal under which the highways would be lighted by lamps affixed to the telegraph poles. The suggestion comes from Mr. A. Allen, who contends that the authorities by placing very large timbers as poles for the telegraph and telephone services were shutting out the light of the roads, and he thought both the main and the district roads should be lighted, and that the authorities that were erecting the poles should be asked to light, if not every second pole, every third one. He thought that the County Council, who derived great revenue from motorists and vehicular traffic, and the postal authorities might help them in the matter.

Fochabers.—The water power to generate the electric light for Gordon Castle and Fochabers was turned on on Tuesday by the Duke of Richmond and Gordon. Mr. Morgan, the Glasgow manager of Messrs. Gorham and Drake, the electrical engineering firm who have the contract; Mr. Miles, the resident manager for the firm; Mr. Ritchie (of Messrs Carrick and Ritchie, Edinburgh, who have had the building up of the turbines) attended. The sluice gates are at the head of a canal which is a mile long, and leads to the power-house. After the sluices were shut and those conveying the water on to the turbines raised, the Duke turned the lever in the power-house, which let the water on to the turbine, the dynamo instantly revolving.

Guernsey.—Sir Henry Giffard, President of the States, on Tuesday inaugurated the new multiple switchboard, forming a principal part of the extensive improvements of the central exchange of the municipal telephone department, and carried out at a cost of £2 600. Major-General Mainguy (chairman of the States Telephone Council), Colonel Bird, and others attended. The new switchboard was built by the International Electric Co. to the special design of Mr. A. R. Bennett. It enables each operator alone to connect any two subscribers. The Guernsey municipal telephone now numbers nearly 1,100 subscribers, being in proportion of one telephone to every 28 inhabitants against one in 70 in London, and one in 40 in Glasgow. Although the charges are low the department has made an annual profit since its formation over and above the amount required for interest on capital, provision of sinking fund, etc.

Lamp Testing.—The Westminster Electrical Testing Laboratory (the Electrical Testing Laboratories, Limited), York-mansion, York-street, Westminster, have published a new scale of fees. This is prefaced with some general remarks, in the course of which it is stated that incandescent lamps on life test are run on a circuit taking current from the Westminster Electric Supply Co.'s mains. The voltage is kept almost absolutely constant at 200 volts by means of a specially designed automatic regulator. The recording voltmeter, which is maintained always on the circuit, shows that the voltage never rises more than 1 per cent. above 200, and this amount only for a minute or so at a time whilst the regulator is coming into action. An excess pressure cut out which can act quickly is connected to the circuit, to act as a safeguard to the lamp in the event of a very sudden rise of voltage occurring, against which the automatic regulator might not act sufficiently quickly. For lamps taking more than 200 volts, cells are added to the circuit to make up to the voltage required. 100-volt lamps are arranged in two banks in series, and are connected to balancing cells, which are capable of maintaining the balance of the voltage should a lamp fail.

Venezuelan Cable.—The *Globe's* New York correspondent wires on Oct. 3 that the fact that the French ambassador and President Roosevelt had a 20 minutes' talk that day appears to be the only foundation for the announcement that Franco-American action of a drastic character is about to be taken against Venezuela. It is asserted now on behalf of President Castro that if the company and the Government had been allowed quietly to arrange matters the price to be paid for the company's land lines would have been settled by mutual concessions weeks ago, and then the Government would spontaneously have allowed the company two more coast stations, and an office in the capital. But according to President Castro, the good diplomats stepped in and spoiled everything. This display of benevolence seems, however, to be overdone. The company concession was granted in 1887, the first cable was landed the following year, and there have been constant troubles ever since, including a period of three years during which the Venezuelan Government prevented the company from doing any business whatsoever. A dispatch from Caracas of Monday's date says the French Cable Company, pending the arrival of its commissioners from France, has consented to the closing of its offices at Caracas and on the coast. Mr. Calhoun, the special United States commissioner to Venezuela, has sailed for home.

Hanley.—The Coventry Town Council are endeavouring, in conjunction with the local chamber of commerce, to seek increased facilities in the public telegraph service, particularly in respect of the provision of a continuous day and night and Sunday service, both for the receipt and delivery of telegrams, being of opinion that such a service should be established in all towns with a population exceeding 50,000. A resolution in favour of a continuous day and night and Sunday telegraph service being established in all county boroughs has been confirmed. The Board of Trade have approved of the Council as undertakers of the Hanley Electric Lighting Order, 1891, connecting the inter-conductor of their high-pressure mains with earth and the connection with earth of the intermediate conductor of the three-wire system at the new post office, their approval to be revoked or varied at any time. The Board also approved the supply of power up to 150 kw. in underground sub-stations of street boxes. An application for an electric motor of 7½ h.p. on the hire-purchase terms has been agreed to, the terms of payment aggregating £33. 10s., spread over two years, and a motor will be ordered for the purpose from Messrs. Brooks, of Huddersfield. Further applications were received which will probably be dealt with from stock. The Electric Lighting Committee are considering a report in which the electrical engineer stated that he had carried out some experiments on street-lighting, and that, with a view to improving the effect of the lamps in Etruria road and Victoria-road, he recommended that silvered glass reflectors be fitted to such lamps as a charge on the lighting rate, in consideration of the electricity department providing two lamps instead of one, maintaining same and supplying the extra electricity required without change in the current prices paid per post for the public incandescent lamps.

Tunbridge Wells.—The Town Council on Wednesday considered a proposal made by Councillor Woollan for the sale of the municipal electric light undertaking to a company. The reasons advanced for this course were that the concern never had paid, and was never likely to do so. It was pointed out by the proposer of the resolution that the general body of ratepayers, whose credit was pledged for £80,000, were not likely to gain a single farthing by the working of the concern, and there was always the possibility of it becoming a charge upon the rates. In his opinion it had reached the limit of its profit earning capacity, and whilst consumers were grumbling at the high rates charged, there was no way by which the prices could be reduced without entailing a call upon the rates. If the concern were sold to a company, it would be developed in a way that the Corporation could not do, and consumers would benefit by getting a better light at a cheaper rate, and the ratepayers would be better off because a larger staff of men would be employed than was the case at the present time. Municipal trading was bad, and the want of success in regard to the Tunbridge Wells electric light was a clear proof of this. Although the accounts showed that a small profit had been made, the arrangements for the repayment of the loan were open to question, and there was no depreciation fund at all. Judged from an ordinary business standpoint, there would be a loss of £2,000 a year instead of a profit of £700. Several members spoke strongly against the proposed sale, and pointed out that the undertaking had made satisfactory progress from the first. It had paid £16,000 off the loans account, contributed £3,000 to the rates, and had a reserve fund of £4 000. It had not cost the rates a single farthing, and was never likely to. In it the town possessed a valuable monopoly, which it would be folly to part with. Alderman Robb, the chairman of the Lighting Committee, said, although convinced that municipal trading was a curse to the country, he would be lacking in his duty to the ratepayers if he did not tell them that they had a very valuable undertaking. It had progressed every year, but it might have done more if the Council had been more sympathetic towards the recommendations of the Lighting Committee. If it was worth keeping at all, it ought to be pushed for all it was worth. He strongly opposed any sale at the present time. On a vote being taken, the Council decided by 17 votes to 7 not to sell the undertaking.

Wireless Telegraphy.—The Gesellschaft für drahtlose Telegraphie, Berlin, report the following work at present being executed by them. Holland: The Dutch military authorities are at the present time making manœuvre trials with transportable stations, and, if satisfactory, a number of military stations will be ordered for their colonies. Several stations of 180 km. range have been ordered. The place of erection is at present unknown; presumably they are required for warships in the Dutch East Indies. Norway: Two stations have been installed on the Lofoten Islands. Turkey: The two large stations—viz., Rhodos, in Asia Minor, and Derna, in North Africa—are nearing their completion, and will most likely be taken into operation in a few weeks, although somewhat great difficulty has been experienced on account of a lack of a sufficiently experienced staff. Peru: Three engineers who have been on the way with the two stations to be installed in the interior of Peru since Feb. 6, have only just arrived in Masisea and Puerto Bermudez, after having met with great difficulties in the transport of the machines

Digitized by Google

and iron towers. This transport, on account of the low level of the water and the many cataracts, had to be effected principally in open boats, the main difficulties being now, however, overcome. The erection of the stations will, therefore, be taken in hand in the course of the present month. Brazil: In August of the present year the Brazilian training-ship "The Benjamin Constan" arrived in Cherbourg, on which occasion complete Tel-funken apparatus were installed. Germany: The "Reichspost" (Government postal service) has, as is well known, been engaged for some time with experiments in wireless telegraphy. Two experimental stations "system Telefunken" having been erected in Berlin, and the results obtained by the same having proved that our system fulfils the high requirements of the Imperial Post, the official stations between Borkum Rift lightship and the lighthouse at Borkum were installed. The establishment of a connection between the Borkum lightship and the naval station at Heligoland was also carried out. The erection of a large station which it had been intended for a long time to build for the purpose of controlling the whole of the North Sea, was also taken in hand. This station is now being installed at Norddeich, near Emden, the preliminary work—viz, the foundations for the towers, the erection of the station house—having already so far progressed that the building of the four iron lattice towers of 60m. to 70m. high, and the putting down of the machines, can now be commenced. Switzerland: The Swiss War Department are installing at the present time two wireless telegraphic stations—system "Telefunken"—for the intercommunication of the fortresses of Rigi-Scheidegg and St. Gotthardt. This department has also purchased from the Gesellschaft für drahtlose Telegraphie m. b. H., Berlin, several portable stations, which are regarded as especially practical for mountainous country.

PROVISIONAL PATENTS, 1905.

SEPT. 25.

19342. Improved magnetic apparatus for advertising purposes. Gustaf Charles Lundberg, 477, Liverpool-street, London.

19345. Improvements in holders and connections for electric incandescent lamps. John Robert Quain, 6, Waterford-road, London.

19355. Improved means for automatically operating gas or other valves or electric switches at predetermined times. Arnold Hare, 111, Hatton-garden, London.

19368. Improvements in brush-holders for dynamo-electric machinery. John Herbert St. Hill Mawdsley, Norfolk House, Norfolk-street, London. (Complete specification.)

19372. Electrically-operated electromagnetic valves. Walter Clifford Northcott, Eyre, Coote Townsend, and Egmont Charles Hoegerstaldt, 5, Great Winchester-street, London. (Complete specification.)

19379. Process for the production of incandescent filaments for electric incandescence lamps. The Deutsche Gasglühlicht Akt.-Ges. [Auer Ges.] 322, High Holborn, London. (Date applied for under Patents Act, 1901. Jan. 17, 1905, being date of application in Germany.) (Complete specification.)

SEPT. 26.

19425. Improvements in and relating to electro-capillary apparatus. Ernest Oldenbourg, 61, Chancery-lane, London.

19447. A new or improved connectors for electric conductors. Edward Wilmer Hill, Norfolk House, Norfolk-street, London.

19483. Improvements in hydraulic lifts electrically operated. Edmond Meyer Tudor Boddam, 23, Savernake-road, London.

SEPT. 27.

19495. Improvements in electric radiators or heaters. Sherard Cowper-Coles, 82, Victoria-street, Westminster, London.

19504. Improvements in trolley pole controllers. Andrew Lafayette Prentise, 18, Southampton-buildings, Chancery-lane, London.

19545. Improvements in and connected with electric meters. John Mesny Tourtel, 33, Cannon-street, London.

19551. Improvements in electrical time switches. Edward Du Bois, Norfolk House, Norfolk-street, London.

19553. Improvements relating to telephones especially adapted for the use of partially deaf persons. Cecil Nathan and John James Leyland, 322, High Holborn, London.

19554. Improvements in indicating or checking devices for use in connection with telephones. Henry Brown Sheldon and Frank Morris Elliott, 6, Lord-street, Liverpool.

19561 Improvements in electric arc lamps. William James Davy, 40, Chancery-lane, London.

SEPT. 28.

19568. Improvements in electrically-controlled semaphore signals for railways. Frank Bartholomew Holt and Arthur Wallis, Telegraph Department, Midland Railway, Derby.

19603. Improvements in and relating to automatic electrical circuit breakers. Crompton and Co., Limited, and Robert Charles Harris, 55, Chancery-lane, London.

19616. Improvements in electric batteries. Georges Schauli, 173, Fleet-street, London.

19631. Improvements in primary electric batteries. Majs Christensen, 40, Chancery-lane, London.

19633. Improvements relating to sockets for holding electric lamps and the like. Frederick Millington, 322, High Holborn, London.

19638. Process for the electrolytic production of copper. Johannes Albert Wilhelm Borchers, Franz Emil Güsher, and Paul Rudolf Frankf, 53, Chancery-lane, London. (Date applied for under Patents Act, 1901, Oct. 4, 1904, being date of application in Germany.) (Complete specification.)

SEPT. 29.

19657. Electric transformer controller. George Tilden Hanchett, De Witt Clinton Conkling, and John Edward Winn, 57, Barton-arcade, Manchester. (Complete specification.)

19680. An improved form and method for holding and insulating flexible cords and wires in connection with electric lampholders and other electric appliances. Frank MacCallum, 61, Piccadilly, Manchester.

19684. Improved means of attaching and detaching the reflectors of electric lights. Walter Bell, 4, St. Ann's-square, Manchester.

19698. Improvements in electric lighting apparatus for shop-window lighting and the like. Henry Langdon Vickery, 5 Budge-row, London.

19706. Improved replacement action for intercommunication telephones. William John Roach, 5, Palmer-street, Westminster, London.

19712. Improvements in or relating to electric arc lamps. André E. Blondel, 111, Hatton-garden, London. (Complete specification.)

19719. Improvements in reflectors for electric arc lamps. Milton Victor Ely and Edwin Rudolph Grote, Worple-road, Wimbledon, Surrey. (Complete specification.)

19746. Improvements in or connected with trolley heads for electric tramcars or the like. Frank Hewer, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

SEPT. 30.

19752. Improvements in road vehicles. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Allgemeine Elektricitäts-Ges., Germany.) (Complete specification.)

19753. Improvements in insulated belts for electric tramway systems and the like. James Haydock and Thomas Smith Jones, Penny Bank-chambers, Halifax. (Complete specification.)

19816. Improvements in or relating to electrical fuse or cut-out boxes. Robert Rumney and Henry Hepher Bishop, Birkbeck Bank-chambers Chancery-lane, London.

19819. Improved device for strengthening telephone currents. Franz Oprendek, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

19823. Improvements in or connected with means for supporting and insulating overhead conductors for electric tramways or railways. Frank Hewer, 221, Birkbeck Bank-chambers, Southampton-buildings, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Oct. 19.

1904.

20877. Magnetic separators. Goodwin and Hollidge.

21962. Dynamo-electric machines. British Thomson-Houston Company, Limited, and Clinker.

23097. Electrical measuring instruments. Fricker.

23109. Electro-capillary apparatus. Armstrong and Orling.

23816 Electric control systems particularly applicable to electrically heated and propelled vehicles. British Thomson-Houston Company, Limited. (General Electric Company.)

23971. Electric device adapted for circuit closing, indicating, power transmitting, and other purposes. Anders and Byng.

24030 Electric time switch or contactor. Jones.

24432 Electro-mechanical synchronisation apparatus. Bonniksen.

24960. Electric brakes or interruptors and means for operating the same. Davis.

25276. Vapour electric lamps, rectifiers, and the like. British Thomson-Houston Company, Limited. (General Electric Company.)

25524. Electric lighting of railway carriages and the like. Imray. (Denham.)

25630. Syatems of control for electrically-operated doors. British Thomson-Houston Company, Limited. (General Electric Company.)

25634. Seals for vacuum tubes. British Thomson-Houston Company, Limited. (General Electric Company.)

25705. Electric projecting lamps chiefly for enlarging and projecting lanterns. Kamm.

25730. Dynamo-electric machines. British Thomson-Houston Company, Limited. (General Electric Company.)

28889. Electric fire-alarm and like circuits. Abrahamson.

Digitized by Google

25963. Apparatus for the distribution of electric current. Atkinson.

1905.

424. Working of single lines of railway on the electric staff or other electric systems. Jacobs.

1281. Devices for use in controlling polyphase and monophase alternating-current motors. Siemens Bros. and Co., Limited, and Berry.

2190. Starting switches for electric motors. Clatworthy, Holmes, Holmes, Holmes, and Holmes.

10647. Electric cables. Smith and Granville.

10804. Single-phase alternating-current meters. Allmänna Svenska Elektriska Aktiebolaget. (Date applied for under International Convention, Sept. 15, 1904.)

10553. Electric arc lamps. Weedon. (Date applied for under International Convention, May 20, 1904.)

11169. Carbon-holders for arc lamps. Siemens Bros. and Co., Limited. (Schuckertwerke, G. m. b. H.)

11329. Device for lowering the vacuum of X-ray and other vacuum tubes. Cressor.

11361. Secondary battery plates Hubbell.

13381. Electrodes for electric arc lamps British Thomson-Houston Company, Limited. (General Electric Company.)

13679. Aerials for the transmission and receipt of electromagnetic wave energy. Fessenden.

15658. Telephone attachments Damico.

15673. Electric lamp bulb and method of and apparatus for finishing same. McDonald. (Date applied for under International Convention, Nov 2, 1904.)

16075. Means for supplying and cutting off currents of high potential to and from conducting lines. Siemens Schuckertwerke, G. m. b. H. (Date applied for under International Convention, Feb. 23, 1905.)
